Austin, TX 78711-3087

Subject: **Response to Third Technical Notice of Deficiency (NOD)**
McCombs Municipal Landfill – El Paso County
Municipal Solid Waste (MSW) Permit No. 729B

Dear Mr. Yadav:

On behalf of the City of El Paso, SAIC Energy, Environment & Infrastructure, LLC (SAIC) is providing the information requested by the Texas Commission on Environmental Quality (TCEQ) third technical notice of deficiency (NOD) letter dated December 18, 2012. A suspension request was granted by the TCEQ for an additional 60 days to the original due date for submittal by March 18, 2013. The TCEQ comment is provided in *italic print* followed immediately by the response. Revised sections and appendices are included as an attachment to this letter and are identified as to the appropriate replacement location in the existing application. It should be noted that the attachment is ordered as to the location of replacement in the existing application, not based on the order of comments.

Part I

1. *The application in some sections, including Part I form indicates that "the application is for a vertical expansion," and does not indicate the proposed increase in the area within the facility boundary. Since the submittal has been updated to increase the area within the proposed facility boundary from 327.29 to 346.74 acres, please revise the application to include this accordingly.*

   The Part I form has been updated and is included in the Attachment.

2. *It appears that the application materials posted on the internet Website prior to the recent submittals have been removed from the Website. Please ensure to post a complete copy of the application, including all revisions and supplements to the application on the internet Website in accordance with 30 TAC §330.57(i).*

   The previous permit application materials have been re-uploaded to the City's website. In addition a complete permit application has been uploaded to reflect the Third Technical NOD.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

3. *The first sentence in Section 1.1.2 of the supplementary technical report references "Permit 729B" as the existing permit. Please correct the sentence to indicate the existing Permit 729A.*

   As per the teleconference call with the TCEQ on December 20, 2012, this item has not been addressed.

Part II

4. *The recent submittal updated the application to increase the area within the proposed facility boundary from 327.29 to 346.74 acres. Please explain if the proposed increase in acreage affects the facility's compliance with the rule requirements of 30 TAC §330.557 relating to Seismic Impact Zones. Please revise Section 2.6.5 (Seismic Impact Zones) as appropriate.*

   The acreage within the proposed facility boundary was increased for this permit amendment from 327.29 to 346.74 acres at the request of the TCEQ to reflect the existing Landfill buildings and retention ponds that were submitted and approved by the TCEQ under Permit Amendment 729A. These features included existing buildings associated with the landfill operations on property previously leased and now owned by the City of El Paso. Retention ponds within this area were designed by Moreno Cardenas, Inc. to handle runoff from existing buildings and infrastructure (Permit Amendment 729-A, December 2010) in accordance with the applicable codes in place at that time.

5. *Please revise Section 2.3 to address the rule requirements of TAC §330.61(h)(4) that the owner or operator shall provide the approximate number of commercial establishments within one mile of the proposed facility including the distances and directions to the nearest residences and commercial establishments.*

   30 TAC §330.61(h) is addressed in Appendix 2B. Appendix 2B has been updated to address commercial establishments.

6. *The first sentence of the last paragraph in Section 2.1.1 (Existing Conditions Overview) indicates that the facility will begin accepting waste in 2014. But, it is stated in Section 1.1.2 (Supplementary Technical Report) and Section 2.2.2 (Projected Waste Acceptance Rates) that the landfill will continue accepting only minimal waste from 2011 through 2013. Please clarify the status of the landfill, and ensure that the narratives provided in the permit amendment application are consistent.*

   Section 2.1 has been updated and is included in the Attachment.

7. *Application drawings including Drawing Numbers P2-8 and P3-33 indicate that a buffer zone has been provided along the permit boundary on the south side of the site. Please explain if the proposed buffer zone will provide safe passage for fire-fighting and other emergency vehicles in*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

accordance with 30 TAC §330.141(b), considering the size of the retention pond planned within the buffer in that area.

The site entrance facilities allow for safe passage for fire-fighting and other vehicles in accordance with 30 TAC §330.141(b) as stated in Section 4.9.6.

8. *Please provide a legend that shows the annotation for the limit of waste line on the appropriate drawings, including on Drawing Number P2-8 (Site Facility Layout), and revise the drawings as appropriate.*

   The limits of waste lines are shown on Drawing P2-8 as the sector boundaries. Please note the existing sector boundaries for the unlined area and for the lined Phase I/II are outside of the new proposed sector boundaries (to the south and west). Drawing P2-8 has been reprinted with darker existing sector boundaries to ease in review (still under revision 2).

9. *Please revise the cross sectional drawings for Sections D and E, to provide full cross sectional details along the south side within the proposed permit boundary.*

   The cross section drawings are provided in Appendix 3F and have been updated to provide full cross sectional details as appropriate.

10. *Please ensure that the application materials indicate "amendment application" instead of "modification application" to reference the current application. Please revise the application materials, including Section 2.6.5 (Seismic Impact Zones) accordingly.*

    Section 2.6.5 was revised to "amendment application" instead of "modification application".

11. *Please replace the word "Attachment" with "Appendix" in the last sentence of Section 2.9 (Floodplains and Wetlands Statement).*

    Section 2.9 has been updated and is included in the Attachment.

Part III

12. *The proposed vertical expansion over waste in existing Pre-Subtitle D area at the site includes placement of up to 55 feet of construction and demolition (C&D) waste before the planned piggy-back liner construction. Please provide justifications for placement of up to 55 feet of C&D waste over the existing waste in the Pre-Subtitle D area. Please note that 30 TAC §330.331 requires compliance with composite liner or alternate liner system prior to placement of waste over Pre-Subtitle D cells.*

    The expansion area of C&D waste will be limited to 30-feet in thickness as discussed with the TCEQ and as presented in the attached updated permit documents. The C&D fill material to be used for the fill will be select materials listed in Section 2.2. The remainder of the fill area

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

needed to establish the base grades for MSW will be consumed by uncontaminated soil. Drawings P3-26B and P3-26C have been added to aid in the review.

13. *Section 3.1.2 (Permit Amendment Overview) indicates that 78 acres of 95 acres will have a piggyback liner, and the remaining 17 acres are currently Subtitle D lined. This does not appear to be consistent with the NOD response dated November 2, 2012. The response referenced Drawing Number P3-28 and indicated that some areas within 78 acres will be provided with a type of final cover profile proposed for the landfill cells that do not have a synthetic bottom liner. Also, Drawing Number P3-45 (Largest Area Requiring Final Closure) indicates "area requiring final cover without a geomembrane liner," which is not consistent with the areas indicated on Drawing Number P3-28. Please revise Section 3.1.4, Drawing Numbers P3-28 and P3-45 as appropriate.*

    Drawings P3-28B and P3-33B have been created to delineate the different base and final cover profiles, respectively. Drawing P3-45 has not been updated as it is intended only for portraying the largest open area at any time of site development. The only instance in which the area shown on Drawing P3-45 will receive final closure is if the piggyback system is not constructed. Section 3.1.2 has been updated with the correct areas (as shown on the previous stated drawings).

14. *Please provide a legend to identify hatched lines with dots in between on Drawing Number P3-45. The proposed area for the final cover appears to be indicated beyond the sector boundary on Drawing Number P3-45. Please explain why a final cover is proposed beyond the sector boundary.*

    Drawing P3-45 provides the largest open area at any time during site development that will require final cover (as required by 30 TAC §330.457(e)(2)). The final cover portrayed is for both the existing and future sector boundary extensions. Drawing P3-45 is only applicable at the time of Sector G development (i.e., prior to the development of the piggyback area). It should be noted final cover will not be placed on the existing unlined (70.8 acres) and lined (20.5 acres) areas prior to the piggyback liner unless the Landfill is closed prior to development of the piggyback area (Sectors H-J) and the vertical expansion of Sector K.

    Drawing P3-33B has been developed to portray the final closure conditions proposed for the Landfill at the time of Landfill closure.

15. *Please clarify if the proposed piggy-back liner system will be provided over the previously closed areas (Drawing Number P3-45), and revise Drawing Numbers P3-28, P3-45, and cross sectional drawings to clearly identify the areas to be provided with the proposed piggy-back liner system.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

The area shown on Drawing P3-45 will not be closed prior to the piggyback liner system. Drawing P3-45 is meant to only show the maximum open area at any given time in accordance with 30 TAC §330.457(e)(2). The only instance in which the area shown on Drawing P3-45 will receive final closure is if the piggyback system is not constructed. Drawings P3-28B and P3-33B have been created to delineate the different base and final cover profiles, respectively.

16. *Please revise the drawings P3-19 through P3-24 (Typical Landfill Sections) to identify the existing top elevations for the previously closed areas (Drawing Number P3-45), and ensure that the permitted elevations for MSW Permit 729A within the proposed 125-foot buffer zone are not increased. Please revise the cross sectional drawings to indicate the permitted elevations as appropriate.*

    The area shown on Drawing P3-45 will not be closed prior to the piggyback liner system. Drawing P3-45 is meant to only show the maximum open areas at any given time in accordance with 30 TAC §330.457(e)(2). The only instance in which the area shown on Drawing P3-45 will receive final closure is if the piggyback system is not constructed. Drawings P3-28B and P3-33B have been created to delineate the different base and final cover profiles, respectively.

    The vertical expansion for the Landfill does not increase the previously permitted elevations outside of the 125-foot buffer. The cross sectional drawings have been updated to portray the previously permitted elevations.

17. *The "Key to Map" provided on Flood Insurance Rate Map is not legible. Please revise the drawing or provide a separate page with an appropriate font size so that the information is legible.*

    A copy of the FIRM without the SAIC border has been provided to help in reviewing the FIRM. Alternatively, the TCEQ may go to the City's website to view the original of the FIRM map at: http://home.elpasotexas.gov/city-development/documents/floodzone/current-flood-maps/4802140004C.pdf

18. *The information provided in the "Project Name" block on Sheet C13 in Appendix 3E does not appear to be consistent with the current amendment application materials. Please provide a revised drawing with appropriate information to be consistent with the current permit amendment application.*

    Drawing C13 has been updated to remove the existing "Project Name".

19. *Please provide a cover letter with responsible engineer's seal and signature over the existing documents (including for Appendix 3B-Attachment 3 (Culvert Calculations), Attachment No. 6 (Erosion and Sediment Control Plan), and Sheet C13) that are proposed to be included into the*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

current amendment application. Please also ensure that the contained information is consistent with the current amendment application.

A memo has been provided for Appendix 3B, Attachment 3 – Culvert Calculations and for Sheet C13. Appendix 3B, Attachment 6 – PSC Erosion and Sediment Control Plan has been removed from the permit amendment application.

20. Appendix 3B (Erosion and Sedimentation Control Plan):

a) Section 3B.2 indicates that "the permit revision 2 dated July 2009 by Parkhill, Smith & Cooper, Inc. (Appendix 3B –Attachment 6 - Erosion and Sediment Control Plan)" is applicable for soil loss calculations and best management practices. Since soil loss calculations are included in Appendix 3B-Attachment 5, please remove soil loss calculations from Appendix 3B-Attachment 6. Also, It is indicated on the cover page that the "portions of the original document are still applicable to the Permit Amendment 729B." Since the document is not fully applicable, it would be confusing to use the document in the future, and therefore, it is requested to submit a new updated document to be applicable for the proposed permit amendment.

Appendix 3B has been updated and is included in the Attachment. The previous Appendix 3B, Attachment 6 – PSC Erosion and Sediment Control Plan, is to be removed from the permit amendment application. Appendix 3B, Attachment 7 is to be updated as Appendix 3B, Attachment 6 – Drainage Calculations. New cover pages are provided in the Appendix.

b) The narratives are not consistent with the proposed amendment application. Please note the followings and revise the content as appropriate.

A. Please provide a tab to indicate Appendix 3B - Attachment 6 to maintain consistency in the document.

Updated tabs have been provided in the Attachment as necessary.

B. Please ensure to update the table of contents, as the table of contents includes "Figure Att6-F-1" and "Figure Att6-F-2," but, these figures are not included in the document.

Appendix 3B, Attachment 6 – PSC Erosion and Sediment Control Plan has been removed from the permit amendment application.

C. Please revise the sentences regarding the total permit area of the site throughout the document, including the first paragraphs of Sections B and C.

Appendix 3B, Attachment 6 – PSC Erosion and Sediment Control Plan has been removed from the permit amendment application.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

D. Please revise the second sentence of the first paragraph in Section C, as the referenced figures are not included in the document.

Appendix 3B, Attachment 6 – PSC Erosion and Sediment Control Plan has been removed from the permit amendment application.

E. Please revise Section D, as the referenced figures Att6-F1 and Att6-F2 are not included in the document.

Appendix 3B, Attachment 6 – PSC Erosion and Sediment Control Plan has been removed from the permit amendment application.

F. Please revise Section E.1, as the referenced figure Att6-2b is not included in the document, and "DA-B" and "DA-C" are not provided as referenced.

Appendix 3B, Attachment 6 – PSC Erosion and Sediment Control Plan has been removed from the permit amendment application.

21. The table of contents and the narratives provided in Attachment 3 (Appendix 3I) are not consistent with the amendment application. Please revise the followings as appropriate.

a) Please replace the table of contents with a clean version, as it includes a strike-out version.

b) Please revise the first sentence of the last paragraph, as the referenced Figure Att15-2 is not included in the current application.

Appendix 3I, Attachment 3 has been updated and is included in the Attachment.

22. The cover pages provided for Appendix 3B –Attachment 6 (Erosion and Sediment Control Plan), and for Attachment 3 (Appendix 3I) indicate "Appendix 6-F, Revised July 2009," and "Attachment 15, Revised July 29, 2002" respectively. This is not consistent with the current application which is yet to be approved. A new cover page with a cover letter would be required to use the existing document, and unrelated information to the current application needs to be removed. Please revise the cover pages as appropriate.

Appendix 3B, Attachment 6 has been incorporated into Appendix 3B. Appendix 3I, Attachment 3 has been updated and is included in the Attachment.

23. It is stated throughout Appendix 3J (Liner Quality Control Plan) of the application that the "owner's representative (OR)" will be responsible for the implementation of field inspection and testing activities under the direction of the professional of record (POR). Please revise Appendix 3J including Section 3J.2 to be consistent with the rule requirements of 30 TAC §330.339(a)(2) that the POR who signs the soil liner evaluation report or his representative should be on site during all liner constructions.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

The Liner Quality Control Plan has been updated to remove the reference of an "owner's representative". A reference to the "POR Representative" has been included for select personnel at the discretion of the POR to perform tasks associated with liner construction and inspection on behalf of the POR. As indicated in the Liner Quality Control Plan, the POR will sign and certify all construction documentation reporting associated with liner construction projects.

24. *Please provide the following details for the proposed liner system in accordance with 30 TAC §330.339(b)(2)(A). Details shall be depicted on cross-sections of a typical cell showing the slope, widths, and thicknesses for compaction lifts.*

    a) details for the overexcavation and recompaction of the in-situ soils, and

    b) details for the compaction of soils from a borrow source.

    Compaction lift details showing the details for the overexcavation and recompaction of the in-situ soils and showing the compaction of soils from a borrow source are depicted in Figures 3J-1 and 3J-2 of the Liner Quality Control Plan.

25. *Please include a requirement for thickness measurement frequency for the proposed compacted caliche layer under Table 3J.1, and also indicate that the thickness measurement report will be included in the Soil Liner Evaluation Report (SLER). It is recommended to include a test frequency of 1/5,000 ft2 for floor area, and 50-ft cross-sections for horizontal-lift sidewall liners, if facility intends to construct horizontal-lifts.*

    Table 3J.1, Item 2 has been updated to include a "Layer Thickness" test requirement using survey methods to verify a minimum, compacted, in-place thickness of 6-inches for the caliche soil layer. Section 3J.8.8 has been updated to include a requirement that all record surveys will be included in the SLER and GLER.

26. *30 TAC §330.339 (a) requires the facility to identify a minimum test frequency for each of the test procedures in a specific manner, including for GCL Index Flux, GCL Permeability, and for GCL Hydrated Internal Shear Strength, which are indicated as "weekly" and "Periodic" respectively in Table 3J.1. Please explain how the indicated frequency will be achieved in compliance with the conformance testing requirements. Please note that the TCEQ's recommended test frequency for conformance test for these properties is 1/100,000 sq. ft.*

    Table 3J.1 has been updated with specific testing frequencies for the GCL material. In addition, geotextile fabric testing requirements and moisture content testing has also been included in the table to better align with testing specifications listed in the Geosynthetic Research Institute (GRI) Specification GCL3.

27. *Please include manufacturer's tests, test methods, and frequency of testing for all materials used in the manufacturing of the geomembranes to determine their quality and suitability for use.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

HDPE geomembranes resin must be tested by the geomembrane manufacturer for density and melt index. Also, the manufacturer's tests on the geomembrane may include thickness, density, carbon black content, carbon black dispersion, tensile properties, tear resistance, puncture resistance, and for dimensional stability (Shrinkage). Please revise the proposed Liner Quality Plan (LQCP) as appropriate.

Table 3J-1, Item 6 notes testing requirements for geomembrane for material conformance. The tests listed in Table 3J-1, Item 6 include sheet thickness per ASTM D5994, specific gravity per ASTM D1505, asperity height per ASTM D7466, tensile strength yield and tensile strength break per ASTM D6693, elongation at break and elongation at yield per ASTM D6693, carbon black content per ASTM D1603 or ASTM D4218, carbon black dispersion per ASTM D5596, tear resistance per ASTM D1004, puncture resistance per ASTM D1004, puncture resistance per ASTM D4833 and direct shear testing per ASTM D5321.

No revisions to the Liner Quality Control Plan appear to be warranted as the existing version provided on 11/2/12 includes the testing requirements listed in this comment.

28. *Please note that a continuous, non-destructive testing shall be performed on all HDPE geomembrane seams by the installer. Air-pressure testing on dual-track fusion welds and vacuum-box testing for extrusion welds are the only acceptable test methods for HDPE geomembrane seams. Also, all factory seams in addition to field seams should be non-destructively tested, and all indicated leaks must be isolated and should be repaired. Please revise the LQCP to address the tests requirements, including passing criteria for the tests.*

Section 3J.8.5 details non-destructive testing requirements for HDPE geomembrane seams. It states, "the entire length of each seam weld will be nondestructively tested and certified for continuity and water-tightness in the presence of the POR representative using air pressure or other appropriate methods."

Section 3J.8.5 also details testing requirements for identified liner leaks, "repair or replacement is subject to the same nondestructive testing as other geomembrane liner seams."

A statement has been included in Section 3J.8.5 to indicate that "Factory seams are subject to the same testing requirements as field seams."

Non-destructive seam test passing requirements were added to Section 3J.8.5 to read, "The air channel that results between the dual bonded tracks will be inflated using a hypodermic needle and pressurized to approximately 200 kPa (30 pounds per square inch). There is no limit as to the length of seam that is tested. If the pressure drops within an allowable amount in the designated time period (typically 5 minutes), the seam is deemed acceptable. If an unacceptable drop in pressure occurs, a number of actions may be taken:

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

- The distance may be systematically halved until the leak is located.
- The section may be tested by some other leak detection method.
- An extrusion fillet weld may be placed over the entire edge.
- A cap strip may be seamed over the entire edge.

For non-destructive seam testing using a vacuum chamber or vacuum box will be performed by placing a transparent top over the seam. A soapy solution is placed over the seam. A vacuum of approximately 20 kPa (or 3 psi) is then applied. The top is held over the seam for approximately 10 seconds. When a leak is encountered, the soapy solution shows bubbles, which reduces the observed vacuum. If the vacuum is held and no bubbles observed, the test is deemed acceptable. Vacuum box testing will only be applied in areas where a level testing surface is present. Vacuum box testing will not occur over areas of the leachate collection sumps, anchor trenches, pipe penetrations or any other locations where the vacuum box top will not be able to provide a seal over the test area."

Section 3J.8.5 also states, "The geomembrane will be tested for potential holes and liner defects again after the protective sand layer has been placed over the geomembrane. The leak location detection testing will be performed in accordance with ASTM D 6747."

29. *In accordance with 30 TAC §330.339(c)(2) and (3), all field sampling and testing, both during construction and after completion of the lining, shall be performed by a qualified professional experienced in geotechnical engineering and/or engineering geology, or under his direct supervision. All liners should have continuous on-site inspection during construction by the professional of record or his designated representative. Please revise LQCP, including Section 3J.8.5 as appropriate.*

    Section 3J.8.5 states, "The POR and/or POR representative will provide continuous construction oversight during the deployment of the geomembrane and will directly oversee testing of trial welds, seams and repairs. Documentation retained during the installation of the geomembrane will be used in preparation of the soil and geomembrane liner evaluation report (SLER and GLER)."

    No revisions to the Liner Quality Control Plan appear to be warranted as the existing version provided on 11/2/12 includes the continuous inspection requirements listed in this comment.

30. *It is stated in Section 3J.7 that minimum passing criteria may be modified based on the site design considerations. Please explain those site design considerations, and note that a permittee or registrant may implement a modification to an MSW permit or registration provided that the permittee or registrant has received prior written authorization for the modification from the*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

executive director in accordance with 30 TAC §305.70(e). Please revise the section as appropriate.

The statement included in Section 3J.7, "Minimum passing criteria may be modified based on the site design considerations (i.e. available borrow source material, unforeseen site conditions) during the preparation of the project plans and specifications." has been removed from the Liner Quality Control Plan.

31. *Please revise Section 3J.8.1 to ensure that the top of the finished subgrade will be surveyed for topographic elevations by a registered surveyor prior to the placement of a caliche layer, and a survey report will be included into the SLER.*

    Section 3J.8.1 states, "Prior to the placement of the caliche (if used for the cell construction), the top of the finished subgrade will be surveyed for topographic elevations at a minimum rate of one survey point per 5,000 square feet of cell liner limits."

    Section 3J.2 has been updated to include the statement, "Any references to surveying contained within this LQCP shall be required to be performed by a professional land surveyor registered in the State of Texas."

    Section 3J.8.8 has been updated to include a requirement that all record surveys will be included in the SLER and GLER.

32. *Please address the rule requirements of 30 TAC §330.339(c)(6) that permeability tests for proving the suitability of soils to be used in constructing liners shall be performed in the laboratory using the procedures and guidance of paragraph 30 TAC §330.339(c) (4)(A). Field quality control must be provided by field density tests based on predetermined moisture-density compaction curves, Atterberg limits, and laboratory permeabilities of undisturbed field samples of compacted liner soils.*

    Table 3J.1 includes permeability testing requirements proving the suitability of soils to be used in constructing liners, along with testing procedures. No revisions to the Liner Quality Control Plan appear to be warranted as the existing version provided on 11/2/12 includes the referenced testing requirements and procedures listed in this comment.

33. *Section 3J.8.5 references a "composite liner system" instead of the proposed "alternative liner system." In accordance with 30 TAC §330.3(29), composite liner is a liner system consisting of two components: the upper component must consist of a minimum 30-mil geomembrane liner or minimum 60-mil high-density polyethylene, and the lower component must consist of at least a two-foot layer of re-compacted soil deposited in lifts with a hydraulic conductivity of no more than 1 x 10-7 centimeters/second. The geomembrane liner component must be installed in direct and uniform contact with the compacted soil component. Also, when referring to liners in the*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

application, please reserve the word "prescriptive" for designs that conform exactly to the design described by 30 TAC §330.331(a)(2) and (b). Please revise Section 3J.8.5 as appropriate.

The use of the term, "composite liner system" included in the LQCP was based on the common use of the phrase within the solid waste industry to refer to a liner system that contains two barrier layers. It was not intended to reference any definitions contained within the State of Texas rules and regulations. The phrasing has been removed from the LQCP to ease any confusion the TCEQ staff or the general public may have with the use of this terminology.

34. *30 TAC §330.339(c)(7) requires that a field permeability testing of in-situ soils or constructed soil liners shall be in accordance with ASTM D5093 for those liners that are in the floor of the excavation and a variation of the Boutwell STEI field permeability test approved by the executive director for the sidewalls. Please address the rule requirements including for the proposed caliche layer.*

    Note 1 on Table 3J.1 has been updated to remove the reference to subpart 4(A) under 30 TAC §330.339 (c).

35. *30 TAC §330.339(c)(8) requires that all quality control testing of soil liners shall be performed during the construction of the liner. In no instance shall any quality control field or laboratory testing be undertaken after completion of liner construction, except for that testing which is required of the final constructed lift, confirmation of liner thickness, or cover material thickness. Please address the rule requirements as appropriate.*

    Table 3J.1 has been updated so that the testing designation as "In-Place" for Items 1 and 2 shall be read, "During Placement".

36. *Please ensure that all soil testing and evaluation of constructed soil liners shall be complete prior to installing the leachate collection system in accordance with 30 TAC §330.339(c) (9).*

    A statement has been added to section 3J.8.7 to read, "All soil testing and evaluation of either in-situ soil or constructed soil liners shall be complete prior to installing the leachate collection system."

37. *Please address the rule requirements of 30 TAC §330.341(d) that the surface of a constructed soil liner should be covered or otherwise protected within a period of six months to mitigate the effects of dessication, surface erosion, and rutting due to traffic. Liner surfaces not covered within six months shall be checked by the soil liner evaluation report evaluator, who shall then submit a letter report on the findings to the executive director. Any required repairs shall be performed promptly. A new report shall be submitted on the new construction for all liners that need repair due to damage.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Section 3J.8.2 states, "The surface of a constructed soil liner should be covered or otherwise protected within a period of six months to mitigate the effects of dessication, surface erosion, and rutting due to traffic. Liner surfaces not covered within six months shall be checked by the POR and/or POR representative, who shall then submit a letter report on the findings to the TCEQ. Required repairs shall be performed promptly. A new SLER shall be submitted on the new construction for all liners that need repair due to damage."

No revisions to the Liner Quality Control Plan appear to be warranted as the existing version provided on 11/2/12 includes the protection inspection and reporting requirements listed in this comment.

38. *Please revise Section 3J.8.8 to replace "TCEQ Municipal Solid Waste Division" with "TCEQ Municipal Solid Waste Permits Section."*

    Section 3J.8.8 has been updated to reflect the current nomenclature used.

The following comments are provided by Mr. Arten Avakian, P.G., of the Texas Commission on Environmental Quality (TCEQ), MSW Permits Section. *These comments are regarding the alternative liner and overliner designs for the referenced facility, based on review of Sections 3.4.1.6 (Liner Quality Control Plan) and 3.4.1.7 (Final Cover Quality Control Plan) of the Part III narrative, and Appendix 3J (Liner Quality Control Plan; mainly Attachment 1, Multimed Modeling Results) to Part III of the application.*

Part III Narrative

39. *Please revise Section 3.4.1.6 to refer to both of the bottom liner designs (detailed in Tables 3.4-1 and 3.4-2) as alternative liner designs, and use the terminology established in Appendix 3J, Liner Quality Control Plan (LQCP): "Scenario 1 Liner System" for the design that has existed for MSW Permit No. 729A, and "Scenario 2 Liner System" for the additional alternative bottom liner.*

    Section 3.4 has been updated and is included in the attachment.

40. *In Tables 3.4-1, 3.4-2, and 3.4-3:*

    a) *In the rows currently labeled "composite liner," replace the word "composite" with a more accurate term (for example, "compacted soil" and "GCL barrier"). The word composite implies multiple layers with distinct properties, which is not the case for a single component.*

    b) *Indicate the hydraulic conductivity value for the geomembrane (HELP models use a value of 2 x 10-13 cm/sec).*

    c) *Indicate the thickness specification for the GCL component (a non-zero value is used in models).*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Section 3.4 has been updated and is included in the attachment.

Appendix 3J, Attachment 1 (*Multimed Modeling Results*)

41. *The distance to the point of compliance (POC) is reported in the text to be 125 feet; however, Figure 20 in Appendix 3K, Attachment 1 (Site Characteristics and Monitoring Plan) indicates that at its closest point the POC is only 30 or 40 feet from the downgradient boundary of the waste management unit. Please ensure that modeling is performed using the shortest distance to the POC.*

    The input parameter for the POC within the MultiMed model was changed to 10 meters or approximately 33 feet.

42. *The discussion of source parameters indicates the source area was limited to just 22.61 acres (91,500 square meters). For complete demonstration, the model should be based on a source area equal to the maximum area that would be underlain by an alternative liner. In the Multimed modeling for this site in 1995, the area was 881,000 square meters (217.7 acres). In the permit amendment under review, it appears there will be three types of alternative liners: Scenario 1 (the alternative bottom liner in MSW Permit No. 729A), Scenario 2 (proposed alternative bottom liner), and Scenario 3 (proposed "piggyback" overliner). Please discuss how to evaluate the relative contributions to the alternative liner demonstration from the three different liners. A simpler method may be to model the entire alternative-lined area using inputs for just one of the three designs.*

    The area for the Multimed model was changed to reflect the entire waste area of 881,000 square meters.

43. *Please address the following comments regarding infiltration rate for Multimed:*

    a) *The discussion of source parameters reports a liner leakage rate of 0.000015 (1.5 x 10-5) inches/day (from page 9 of the HELP model output in Appendix 3J, Attachment 1), and states that the equivalent is 0.000314 (3.14x10-4) meters per year. Please provide calculations showing how you converted from inches to meters (our calculation yielded 1.39 x 10-4 meters/year).*

    The TCEQ's calculation is correct, the source parameter was changed to 1.39 x 10-4 meters/year.

44. *The HELP model in Appendix 3J, Attachment 1 uses a lower hydraulic conductivity value (3x10-9 cm/sec) for the GCL than the upper limit (5x10-9 cm/sec) specified in Section 3.4.1.6 of the Part III narrative and in the Liner Quality Control Plan (LQCP) in Appendix 3J. Please rerun HELP models using the hydraulic conductivity limit specified in the LQCP.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

The HELP models have been re-run using the $5x10^{-9}$ cm/sec permeability value for the GCL. The updated models resulted in a few minor changes to Table 3I-2 in Appendix 3I. The values have been updated accordingly.

45. Please address the following comments regarding the Multimed modeling:

a) Reformat the model printouts to prevent "wrapping" of the text and overprinting by page footers, which makes the output difficult to read.

The Multilmed printout was reformatted for printing.

b) Evaluate and explain whether the input of a non-zero value (152 ml/g) for the chemical specific variable "normalized distribution coefficient" affects the output contaminant concentration. Normalized distribution coefficient is apparently relevant to retardation processes; for the purposes of an alternative liner design demonstration, models should be run using fate and transport assumptions that maximize contaminant migration (for example, no retardation or degradation of contaminants). Such an approach reduces the number of variables and associated uncertainty, and is consistent with the principles that apply to the groundwater monitoring system that is designed to detect any contaminants that may leak through the liner.

We will review the model results again after the application has been revised.

The "normalized distribution coefficient" parameter was set at zero (0) to reflect no retardation in the subsurface and present the most conservative scenario.

Appendix 3J, Attachment 2 (*Alternative Liner Modeling ("Prescriptive Liner")*)

46. Please include a copy of the June 1995, revised alternative liner design modeling report. The report consists of a letter report and attachments from Anderson Consultants to the City of El Paso, dated June 26, 1995, under a cover letter from the city to the Texas Natural Resource Conservation Commission, dated June 30, 1995.

The requested letters and attachments have been added to Appendix 3J, Attachment 2.

The following comments are provided by Mr. Jason Wang, P.G., of the TCEQ, MSW Permits Section.

47. Please address the comments (TCEQ Letter dated December 3, 2012) provided by Mr. Arten Avakian from his review of the Site Characterization and Monitoring Plan (SCMP) submitted in response to the permit modification for MSW Permit 729A (dated January 2, 2008) and subsequent revisions. Please ensure that your response will revise appropriate sections and references to the current permit amendment application number 729B.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

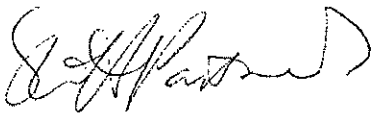
The SCMP has been updated based on discussions with TCEQ staff and is provided as Appendix 3K.

48. *Please explain the discrepancy in the allowable runoff values of 100% in Appendix 3I for the Leachate and Contaminated Water Plan versus 0% of precipitation in Table 3N-7 for the UNSAT-H model.*

The runoff values assigned in each of the models was selected to be the most conservative value for the method of evaluating water balance in the Landfill cover. The HELP model's primary purpose is to provide water balance evaluation within a conventional barrier-type cover by placing primary emphasis on the properties and function of barrier and drainage layers located above and below the waste. Using a 100% runoff value for the HELP model is conservative in verifying that the stormwater collection and transfer structures are sized adequately to facilitate the volume of expected precipitation and runoff. The HELP model does not adequately address the movement of water through the cover into waste percolation, which is why it is not used as a tool to model evapotranspiration covers. However, the UNSAT-H model simulates water flow throughout a soil cover using more rigorous theoretical methods, which is why it is commonly used to model evapotranspiration covers. Using a runoff value of 0% is the most conservative scenario because it models the maximum of amount of precipitation that infiltrates through the soil cover. In addition, TCEQ Guidance for Requesting a Water Balance Alternative Final Cover for a MSW Landfill (January 2012) states that, "The annual percentage of runoff generated by the model is expected to be less than 10 percent of total water applied (precipitation and irrigation)." In summary, the runoff values used for the models are different because the models evaluate water flow parameters differently. In each case, the most conservative value is applied.

Sincerely,

SAIC Energy, Environment & Infrastructure, LLC



Scott Pasternak
Assistant Vice President

Cami Van Abel, P.E.
Environmental Engineer

c w/encl: Miguel Parra, City of El Paso

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

November 2, 2012

Chandra S. Yadav
Project Manager
Texas Commission on Environmental Quality, MC 124
P.O. Box 13087
Austin, TX 78711-3087

Subject: **Response to Second Technical Notice of Deficiency (NOD)**
McCombs Municipal Landfill – El Paso County
Municipal Solid Waste (MSW) Permit No. 729B

Dear Mr. Yadav:

On behalf of the City of El Paso, SAIC Energy, Environment & Infrastructure, LLC (SAIC) is providing the information requested by the Texas Commission on Environmental Quality (TCEQ) second technical notice of deficiency (NOD) letter dated September 7, 2012. A time extension request was granted by the TCEQ for an additional 30 days to the original due date for submittal by November 6, 2012. The TCEQ comment is provided in *italic print* followed immediately by the response. Revised sections and appendices are included as an attachment to this letter and are identified as to the appropriate replacement location in the existing application. It should be noted that the attachment is ordered as to the location of replacement in the existing application, not based on the order of comments.

Furthermore, it should be noted that this major permit amendment also increases the permitted/facility area from 327.292 acres to 346.74 acres within Section 6, Block 80, Township 1, Texas and Pacific Railway Survey to include the site entrance facilities within the permitted/facility boundary. An updated metes and bounds is provided in Appendix 1C.

1. *The submittal includes the terms "existing and proposed" throughout the application, including on Drawing P0-2.0 (Abbreviations and Legend). The use of such terms will be confusing after an approval of the amendment application. Please ensure to revise such terms so that there will not be any confusion after approval.*

   The permit amendment has been updated throughout to remove the use of the word "proposed". The use of the word "existing" is still used in the document to describe existing conditions at the time of amendment preparation. All pages are dated to provide a time stamp on the "existing" terminology.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

2. *Drawing P0-2.0 (Abbreviations and Legend) does not provide a legend for the facility boundary. Also, it indicates a common legend for "buffer zone/waste limit." Please be informed that a buffer zone shall be free of municipal solid waste processing and disposal activities within and adjacent to the facility boundary on property owned or controlled by the owner or operator in accordance with Title 30 Texas Administrative Code (30 TAC) Section §330.3(19). Please provide cross sections to identify the buffer zone along the facility boundary for the locations proposed for the vertical expansion, and also provide appropriate legend to indicate the buffer zone, the facility boundary and the limit of waste.*

   The facility boundary has been updated to be synonymous with the property boundary. The existing waste limit permitted previously complies with the 50-foot buffer limit established under the previous rules. Any vertical expansion beyond the original permitted heights complies with the 125-foot buffer zone. Areas outside of the 125-foot buffer zone may contain waste (i.e., between the original permitted 50-foot buffer and the 125-foot buffer); however, no waste will exist between the 50-foot buffer zone and the property boundary. The cross-sections provided as Drawings P3-19 through P3-24 have been updated to portray the buffer zones. Drawing P0-2 has been updated to reflect these changes.

3. *Some of the attachments and appendices do not include cover page and table of contents (e.g., Appendices 3B, 3I and 3J). Please ensure to provide cover pages and table of contents, and also ensure to provide a page number for each page.*

   The cover page and table of contents for the appendices is inclusive of the associated attachments within those appendices. The table of contents has been updated to include further description on the attachments.

4. *The drawings are referenced in the text with their original Drawing Number (e.g., Drawing Number P2-7 on Page 2.3-2). But, the revised submittal includes a different number for the drawings (e.g., Drawing Number P2-7.1). Please revise the submittal to correct such discrepancies.*

   All drawings have been updated to remove the revision number from the drawing number (i.e., Drawing P2-7.1 has been updated to now read Drawing P2-7). Revisions to the drawings are indicated in the drawing title block. It should be noted that the revision to the drawing number was not highlighted as a change on the redline version of the drawings (and therefore, if that was the only change to the drawing, a redline version was not provided for review and only the final version was provided).

5. *Some of the labels on the drawings are not legible (e.g., Drawing Number P2-8.1). Please ensure to provide appropriate labels, and legend information on the drawings.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Drawing Number P2-8 has been updated to remove illegible background information and a legend has been provided for clarity.

6. *The revised submittal does not include an original certification statement per 30 TAC §305.44. Please ensure to provide certification statement (Page 10 of the Part I form).*

   An updated Part I form has been provided with this response to comments.

Part I

7. *The page for metes and bounds descriptions for the proposed easement area of 19.442 acres in Appendix 1C indicates a note on the left top corner as "McCombs Landfill+PSB Leased Area." Also, Drawing P0-2.0 indicates a legend for "PSB Lease Area." Please revise to delete "leased area" since the City owns the property.*

   An updated Metes and Bounds survey has been provided within Appendix 1C. It should be noted that the facility boundary has been revised to coincide with the property boundary (as indicated on Drawing P0-2 and associated drawings).

8. *Please ensure that the easement area is included within the property boundary, and ensure to revise the related drawings, including Drawing Number P2-8.1 as appropriate.*

   The drawings have been updated to either remove or enhance items screened within the background of the drawings. The cross-sections provided as Drawings P3-19 through P3-24 have been updated to portray the 50-foot and 125-foot buffer zones (easement areas) as described in the response to Comment #2.

Part II

9. *The site facility layout (Drawing Number P2-8.1) indicates a label as "New Site Entrance Facilities" within the proposed easement area of 19.442 acres. Please clarify if "New Site Entrance Facilities" includes a gate-house. Please note that a gate-house may not be allowed outside the facility/permit boundary. Please also ensure to identify the components of "New Site Entrance Facilities," and revise the site facility layout as appropriate.*

   The facility/permit boundary for the site has been updated to 347 acres as portrayed on Drawing Number P2-8. The new site entrance facility is shown in more detail on Drawing P3-17 (as indicated). The scale house indicated on the drawings is synonymous with a gate-house.

10. *The supplementary technical report indicates that the facility plans to accept Class 3 inert wastes on top of the existing unlined landfill. In accordance with 30 TAC §330.61(b)(1), the owner or operator shall identify the sources, characteristics and chemical composition of wastes proposed to be received for storage, processing, or disposal. Please revise Section 2.2 (Waste Acceptance Plan) to include the sources, characteristics and chemical composition of wastes.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Section 2.2 has been updated to include the sources, characteristics, and chemical composition of the wastes intended to be accepted at the McCombs Landfill. It should be noted that the Landfill intends to dispose of inert construction and demolition debris (Class 3 like); not actual Class 3 waste.

11. *Please clarify if the property boundary and the facility boundary are indicated synonymously on the drawings, including on Drawing P3-4. Please revise the drawings to make sure that the property boundary and the facility boundary are clearly defined. Please also update Drawing Number P0-2.0 (Abbreviations and Legend) as appropriate.*

    The facility boundary has been updated to coincide with the property boundary (347 acres) as indicated on the revised drawings.

12. *Please clarify if the facility will have a perimeter road, as the interior facility roadways for most of the units/cells are proposed to connect the perimeter of the landfill site. Also, the drawings (Drawing Numbers P2-11.1 through P2-18.1) do not show the continuity of roadways between the entrance gate and the interior facility roadways to access fill areas of the landfill units/cells. Please revise the drawings to provide the information as required by 30 TAC §330.61(d)(2).*

    Drawings P2-11 through P2-18 have been updated to better show the perimeter roads for the facility. The perimeter roads connect in with the proposed interior facility roadways as shown. In addition a legend has been added to the drawings to better indicate the existing roadways.

13. *Please identify the existing earthen berms as stated in Section 2.3.2 along the western and northern boundaries of the landfill, and provide a cross sectional details of the berms.*

    The existing earthen berms locations described in Section 2.3.2 are indicated on Drawings P3-19 and P3-22 within Appendix 3F.

Part III

14. *Please include the information that was provided as the response to Comment #15 of the first NOD in Part III of the application, and elaborate the narrative to comply with the rule requirements of 30 TAC Chapter 330, Subchapter M: Location Restrictions, as applicable to the facility.*

    The information provided as Comment #15 of the first technical NOD is included in Appendix 3K, Attachment 4. The memo within Appendix 3K, Attachment 4 has been expanded to include the referenced information.

15. *The revised application contains references to the existing permit (MSW Permit No. 729A) on cover pages, in headers and footers of pages, and in narratives of Appendix 3B, Appendix 3I and Appendix 3J. Please note, if this permit amendment application is approved, it will replace*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

document of Permit No. 729A. Please ensure to provide the proposed permit application number (MSW Permit No. 729B) on cover pages, in headers and footers of pages, and in narratives as appropriate.

Reference to MSW Permit No. 729A has been removed and replaced with MSW Permit No. 729B as applicable. Documents provided for reference only have been provided with a memo to explain the contents.

16. *Drawing C13 of the existing permit (MSW Permit No. 729A), prepared by Moreno Cardenas Inc. has been included in Appendix 3E of the submittal. Please update the drawing with the proposed permit application number (MSW Permit No. 729B).*

    Reference to MSW Permit No. 729A has been removed and replaced with MSW Permit No. 729B on Drawing C13.

17. *It is stated in the revised Section 3.3.1.3 that a stormwater basin will be developed as fill progresses and interim phases are built. Please identify location and a cross sectional details for the proposed basin, and discuss about the fate of the basin as fill progresses.*

    As described in Section 3.3.1.3, the mined pit area will act as a natural low-lying retention basin during interim phases of Landfill operation (applicable to Sectors A through F). The low-lying areas will be graded during Sector construction so that drainage is away from the developed Sector, preventing run-on. The natural low-lying retention basins are not designed basins.

18. *Section 3.3.1.3 indicates that the site drainage collection, conveyance, and detention structures are designed to operate during all phases of landfill operation. Please identify the structures to be constructed for necessary drainage collection, conveyance, and detention structures during interim phases of landfill operation.*

    Calculations for soil loss and non-erodible velocities for the interim phases have been provided in Appendix 3B, Attachments 5 and 7, respectively. Interim structures include delineation (run-on, runoff) berms as identified on Drawing P3-29, Detail 4.

19. *The erosion and sedimentation control plan by Parkhill, Smith & Cooper, Inc. (revision 2 dated July 2009) included in Appendix 3B, Attachment 6 has been referenced in the application, including in Section 3B.4. Please ensure to update the cover page information, headers and footers, and the table of contents to show the proposed permit amendment application number (MSW Permit No. 729B).*

    Reference to MSW Permit No. 729A has been removed and replaced with MSW Permit No. 729B.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

20. *Please revise the drainage area identification (DA-1 through DA-8) provided in Attachment 1 of Appendix 3B to make it consistent with Drawing Numbers P3-4.1 and P3-6.1 which appears to be indicated on the drawings as EX-1 through EX-3 for existing conditions, and DEV-1 through DEV-8 for developed conditions.*

    The calculations provided in Attachment 1 of Appendix 3B have been updated to include the correct reference for the drainage areas. It should also be noted that the existing conditions drainage areas (EX-1, etc.) have been updated to include the 19.4 acre entrance facilities area. The new areas for the existing conditions are provided on Drawing P4-4. The developed conditions (DEV-1, etc.) are indicated on P3-6.

21. *Please provide a figure to explain the soil loss calculations with a reference to the types of cover and the length of slopes for the interim and final conditions for each drainage areas at the referenced landfill. Please ensure that the top surfaces and external embankment slopes of municipal solid waste landfill units must be designed to minimize erosion and soil loss through the use of appropriate side slopes, vegetation, and other structural and nonstructural controls during all phases of landfill operation in accordance with 30 TAC §330.305(d)(2).*

    Figure 1 and Figure 2 have been provided in Appendix 3B, Attachment 5 to portray the final and interim slope lengths utilized in the soil loss calculations and to calculate the non-erodible velocities.

22. *It is stated in Section 3.2.3 that "stormwater runoff from the waste mass will be collected in v-ditches around the perimeter of the landfill, and they are designed to convey the 25-year storm event for each drainage basin and will direct the stormwater runoff into existing stormwater retention ponds." Please clarify if the existing stormwater retention ponds are provided with a liner, and ensure that stormwater runoff from the waste mass is managed in compliance with the rule requirements of 30 TAC §330.207 (relating to Contaminated Water Management). Please revise the section as appropriate.*

    It should be noted that the text referenced in Section 3.2.3 is stormwater runoff from the covered waste mass (i.e., not contaminated water) and therefore the existing stormwater retention ponds are not provided with a liner. Section 3.2.3 has been updated for clarification.

    Stormwater runoff from the active waste mass is contained within site run-on/runoff berms as described in Appendix 3I, Attachment 3 – Raba Kistner Leachate and Contaminated Water Plan. In the event that stormwater comes into contact with the active working face and is not contained within the site run-on/runoff berms, it will be managed in accordance with Appendix 3I.3 – Contaminated Water Management.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

23. *Please provide a discussion regarding the fate of collected stormwater runoff into the retention ponds, and also ensure that the existing or permitted drainage patterns will not be adversely altered in accordance with 30 TAC §330.63(c)(1)(C).*

    As stated in Appendix 3B.1.2, the retention ponds on site do not have an outlet structure and water will drain down via infiltration or evaporation.

    As stated in Section 3.3.1.3, the site drainage collection, conveyance, and detention structures are designed to operate during all phases of Landfill construction so that the existing drainage patterns will not be adversely altered. Calculations are provided in Appendix 3B, Attachment 7.

24. *Since the proposed amendment application intends to replace the compacted "six-inch on-site caliche layer" with a geosynthetic clay liner (GCL), please revise the proposed SLQCP to delete the text related to the caliche layer, and replace with GCL as appropriate.*

    The updated Liner Quality Control Plan (LQCP) is provided as Appendix 3J. The updated LQCP includes description for quality assurance/quality control (QA/QC) procedures for three composite liner construction scenarios at the Landfill: one using caliche as the primary liner, one using GCL as the primary liner if caliche is not available for cell construction, and a third describing the "piggy-back" composite liner system for areas where cell construction is planned over existing unlined waste fill.

25. *Since the compacted "six-inch on-site caliche layer" has been proposed to be replaced with a geosynthetic clay liner (GCL), please revise Drawing P3-29.1 (Liner Details) to delete the details provided for the existing liner system. Please provide a constructed liner details, where applicable, shall be depicted on cross-sections of a typical cell showing the slope, widths, and thicknesses for compaction lifts in accordance with 30 TAC §330.339 (a)(1). The amount of compaction shall be expressed as a percentage of a predetermined laboratory density. Please revise the proposed SLQCP, including Drawing P3-29.1 as appropriate.*

    Drawing P3-29 has been updated to indicate the three potential composite liner construction scenarios at the Landfill. Compaction requirements are detailed in the updated LQCP, and summarized in Table 3J.1.

26. *Please ensure that Section 5.2 on page 2 of the proposed SLQCP provides correct information for the proposed leachate collection system, including the diameter of leachate collection perforated and non-perforated pipes.*

    Section 3J.5 of the updated LQCP includes leachate collection pipe diameters.

27. *Please identify "the construction drawing" that is referenced in the proposed SLQCP in Sections 5.3, 6.1 and 6.2.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

The LQCP has been updated and is included as Appendix 3J. The LQCP references drawings included in this application submittal.

28. *30 TAC §330.339(b) requires that that the liner quality control plan shall specify materials, equipment, and construction methods for the compaction of clay soils to form impermeable liners. Please include the following information as appropriate.*

    A. *details for the overexcavation and recompaction of the in-situ soils, or the compaction of soils from a borrow source, shall be depicted on cross-sections of a typical cell showing the slope, widths, and thicknesses for compaction lifts; and*

    B. *procedures to be followed when excavations, cells, or disposal areas extend into or have the potential to extend into the groundwater shall be in accordance with the provisions provided in §330.337 of this title (relating to Special Liner Design Constraints).*

    The updated LQCP discusses scarifying and re-compacting in-situ soils in Section 3J.8. Composite liner details depicting as-built thickness, slope, widths, etc., is shown on Drawing P3-29.

    Hydrogeological reports for the site indicate the depth to groundwater is over 300-feet from the designed subgrade elevations. Therefore, discussion for ballast uplift support, de-watering activities, etc. is not necessary for cell construction at this site.

29. *The proposed SLQCP in Section 9.0 indicates that the drainage aggregate in leachate collection system as "2 inch concrete aggregate." This does not appear to be consistent with Drawing No. P3-31 (Leachate Collection System Details). Please revise the proposed SLQCP to ensure consistency within the application document.*

    The updated LQCP describes the drainage aggregate in the leachate collection system as depicted on Drawing No. P3-31.

30. *30 TAC §330.339(c)(4) requires that all soil tests performed on any in-situ or constructed soil liners shall be in accordance with the standards in subparagraphs 30 TAC §330.339(c)(4) (A) - (E). Please revise the proposed SLQCP, including Section 7.0 (Subgrade Placement and Compaction) to address these rule requirements.*

    Soil test requirements pertinent to the caliche layer (as described in 30 TAC §330.339(c)(4) (A) - (E)) are summarized in Table 3J.1 of the updated LQCP. It should be noted that the existing subgrade is not a component of the soil liner and therefore does not have the same testing requirements as the caliche layer. The prescriptive liner profile (caliche) is modeled in Appendix 3J, Attachment 2.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

31. *Please address the rule requirements of 30 TAC §330.339(c)(9) that all soil testing and evaluation of either in-situ soil or constructed soil liners shall be complete prior to installing the leachate collection system. Please revise the application as appropriate.*

    Soil test requirements are summarized in Table 3J.1 of the updated LQCP. The sections describing the components of the composite liner system detail that each layer of the liner system must be approved by the owner's project representative prior to installation of the subsequent layer.

32. *Please ensure that the test method (ASTM D2216) indicated for the moisture content determination in the proposed SLQCP in Table 3J-4 (Compacted Soil Liner Material Construction Tests) is correct.*

    Table 3J.1 of the updated LQCP lists ASTM D 2216 as the required moisture content determination test.

33. *Please address the rule requirements of 30 TAC §330.339 (e) and (f) that all constructed soil liners shall be keyed into an underlying formation of sufficient strength to ensure stability of the constructed lining, and each soil liner evaluation report shall be prepared in accordance with the approved liner quality control plan. Any deviation from the approved plan must have prior written approval from the executive director.*

    Soil liner construction is described in Section 3J.8.2 of the updated LQCP. Soil and geomembrane liner evaluation reports are described in Section 3J.8.8 of the updated LQCP.

34. *30 TAC §330.339 (g) requires that soil liners shall not be compacted with a bulldozer or any track-mobilized equipment unless it is used to pull a pad-footed roller. All soil liners shall be compacted with a pad-footed or prong-footed roller only. Please also ensure that in all cases soil clods shall be reduced to the smallest size necessary to achieve the coefficient of permeability reported by the testing laboratory and to destroy any macrostructure evidenced after the compaction of the clods under density-controlled conditions. Please revise the proposed SLQCP as appropriate.*

    Soil liner construction is described in Section 3J.8.2 of the updated LQCP.

35. *Please address the rule requirements of 30 TAC §330.341 (a) and (b) that prior to the disposal of solid waste in any cell, or on any area, excavation, or unprotected surface, a soil liner evaluation report and a geomembrane liner evaluation report shall be submitted to the executive director. Each soil liner evaluation report and geomembrane liner evaluation report shall be submitted in triplicate (including all attachments) to the executive director and shall be prepared in accordance with the methods and procedures contained in the approved liner quality control plan. Please revise the proposed SLQCP as appropriate.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

The soil liner and geomembrane liner evaluation reports are described in Section 3J.8.8 of the updated LQCP.

36. *Please provide a statement in the proposed SLQCP that the surface of a constructed soil liner should be covered or otherwise protected within a period of six months to mitigate the effects of dessication, surface erosion, and rutting due to traffic in accordance with 30 TAC §330.341 (d). Please also include in the SLQCP that the liner surfaces not covered within six months shall be checked by the soil liner evaluation report evaluator, who shall then submit a letter report on the findings to the executive director. Any required repairs shall be performed promptly. A new report shall be submitted on the new construction for all liners that need repair due to damage.*

    Soil liner construction is described in Section 3J.8.2 of the updated LQCP.

37. *Please replace "Texas National Resources Conservation Commission (TNRCC)" with "Texas Commission on Environmental Quality (TCEQ)" and "a permit modification" with "a permit amendment" in Attachment 1 (SLQCP) and Attachment 2 (Page 3J-1) in Appendix 3J respectively.*

    The updated LQCP refers to the "Texas Commission on Environmental Quality" as the regulatory agency. Attachment 2 of Appendix 3J is now included as Attachment 1 of Appendix 3J and has been updated to remove and replace the "permit modification" terminology.

38. *Since the proposed amendment application includes the existing soil liner quality control plan (SLQCP) as part of the proposed permit amendment application, please provide an evaluation for the proposed SLQCP, signed and sealed by a responsible engineer with a statement that the enclosed document (Appendix 3J, Attachment 1 – Soil and Liner Quality control Plan) addresses the current rule requirements of 30 TAC, Chapter 330, Subchapter H: Liner System Design and Operation, and will be applicable to the proposed site permit. Please also ensure to update the cover page, headers and footers, and the table of contents for the proposed SLQCP. Alternatively, as the comments #24 through 37 are regarding the proposed SLQCP, we recommend that you revise the proposed SLQCP and resubmit the updated version of the SLQCP with responsible engineer's seal and signature.*

    The updated LQCP complies with the rule requirements of 30 TAC 330, Subchapter H.

39. *The supplemental geotechnical evaluation report prepared by American Engineering Testing, Inc. (AET) in Section 3.0 indicates a factor of safety 1.33 for the assumed interface friction angle of 28° for a seepage flow parallel to the liner for a saturated depth of 0.49 feet (erosion layer side slopes) within the cover soil. The report also indicates that a factor of safety of 1.5 can be achieved for this seepage condition, if both the interface angle and the internal friction angle of the sand cover soils are at least 31°. The minimum factor of safety of 1.5 is considered*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

acceptable for any slope stability analysis. Please explain how the calculated factor of safety of 1.33 will be acceptable.

Based on the soil type needed to achieve a $5.8x10^{-3}$ cm/sec permeability (as modeled in the HELP model and identified in Appendix 3P, Table 3P-1 testing requirements), the erosion layer will also serve as a drainage layer above the geomembrane. As described in the AET Report Dated August 3, 2012, Section 3.0, a slope stability analysis was completed to evaluate the stability of the final cover system as proposed. Assuming the saturated depth of 0.49 feet (maximum calculated from the HELP model) and an internal friction angle of 28°, the factor of safety for the seepage condition would be 1.33. To achieve a FS of 1.5, the internal friction angle of the sand to be used for the soil erosion layer (prescriptive) needs to be 31°. Soils testing will be completed prior to construction to ensure that the internal friction angle of the sand is at least 31° to ensure the 1.5 factor of safety (as indicated in Appendix 3P, Table 3P-1). Published values for the internal friction angle of sand are 26° - 40° and should be readily obtainable from the material onsite.

40. *For the proposed alternate cover system, the AET report in Section 3.0 indicates a factor of safety as 1.41 for a no water flow condition for a friction angle of 25° for both 90% and 80% density sand. Also, it indicates a parallel seepage flow within the sand will lower the factor of safety below 1.0. The minimum factor of safety of 1.5 is considered acceptable for any slope stability analysis. Please explain how the calculated factor of safety of 1.41 and below 1.0 will be acceptable.*

    An internal friction angle of 27° for the sand to be used for the alternative cover is required to increase the factor of safety to 1.5 for the no flow conditions. Soils testing will be completed prior to construction to ensure that the internal friction angle of the sand is at least 27° to ensure the 1.5 factor of safety (as indicated in Appendix 3P, Table 3P-1). Furthermore, it should be noted that the parallel seepage analysis completed by AET does not apply to the alternative cover system as there is no saturation depth for the alternative cover. The alternative cover is designed so that a zone of saturation will never be established as the water entering will be countered by evapotranspiration.

41. *The AET report includes two appendices as "Appendix D." Please ensure that the appendices of the AET report are provided with correct nomenclature and page number.*

    Two separate AET reports were prepared (dated June 1, 2011 and August 3, 2012) for this permit amendment. Updated AET reports with footers have been included along with attachment dividers to separate the two reports (Appendix 3G, Attachment 1 and 2, respectively). In addition, a cover page for Appendix 3G has been included.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

42. The calculations for "Anchor Trench Design for Pullout" and "Interface Liner System Stability" indicate the proposed factors of safety 1.1 and 1.37 respectively. Please explain how the calculated factor of safety of 1.1 and below 1.37 will be acceptable. Also, these calculations are not provided with a cover page and page number. Please provide a cover page, page number, and identify a location for these calculations in the proposed permit document.

The anchor trench was designed with both constructability and strength in mind. The anchor trench should fail and pullout rather than the sideslope geomembrane liner failing and tearing, since it will be easier to observe and repair an anchor trench failure. However, the anchor trench also has to aid in construction, and providing a shallower anchor trench may have issues with wind and water migration under the liner edge. The calculated factor of safety of 1.1 is considered adequate as it shows that anchor trench pullout will be the governing failure mode. Also note that the configuration is temporary as the slope will be filled against after phase construction.

The interface liner system stability calculations are also most critical during and immediately after phase construction (until waste filling begins within the phase) and are a temporary condition. As waste is filled against the slope, the waste creates a buttress to provide more strength against failure. The calculated 1.37 factor of safety is considered adequate for temporary conditions.

Updated anchor trench calculations with pages numbers have been provided for the anchor trench calculations (Appendix 3G, Attachment 3) along with a cover page for Appendix 3G.

43. The memorandum, dated August 8, 2012 included in the submittal does not appear to include all the recommendations of AET report. Please provide a statement in the permit text that the recommendations of the AET report will be implemented in full, if the proposed permit is approved.

An updated memo has been included in Appendix 3G, Attachment 2 to state that all AET recommendations will be followed.

The following comments are provided by Mr. Jason Wang, P.G., of the Texas Commission on Environmental Quality, MSW Permits Section.

Part II

44. Section 2.3.2 Facility Layout Map - We have reviewed your response to our request for additional monitor wells to satisfy the 600 feet maximum spacing at the point of compliance in accordance with 30 TAC §330.403(a)(2). You have stated that a groundwater monitoring system will be submitted for our review once the groundwater assessment is complete. While this proposal is acceptable due to the recent installation of monitor wells PZ-4 and PZ-5 in June,

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

2011 and the required one year monitoring period to determine the groundwater gradient; the assessment should have concluded at this time. Please submit the groundwater monitoring system design within 30 days of the date of this letter. Please note that the processing of this major amendment application cannot proceed until a complete permit amendment application has been submitted.

An updated Site Characteristics and Monitoring Plan has been prepared by Parkhill, Smith and Cooper and was submitted to the TCEQ on October 30, 2012. A copy of this submittal has been provided as Appendix 3K, Attachment 1 for your information.

Part III (Appendix 3P - Final Cover Construction Quality Control Plan)

45. *Please revise the proposed minimum test frequency at the borrow source from one test per soil type to one test per 1000 cubic yards of placed material to verify soil classification. In addition, the permeability testing should be conducted using undisturbed large block samples at a minimum frequency of one test per lift and one test per 10,000 cubic yards of placed material. Please refer to TCEQ Regulatory Guidance Document RG-494, Guidance for Requesting a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill, dated January, 2012.*

Appendix 3P has been updated to include the testing requirements as described above.

Part IV

46. *Section 4.9.3 Facility Hours – Please address the following:*

A. *The currently permitted (MSW Permit No.729A) waste acceptance hours for the facility is 7:00 a.m. to 4:00 p.m., six days a week as stated in the Site Operating Plan dated February 2007. If the facility's intention is to expand the waste acceptance hours to 6:00 a.m. to 7:00 p.m., seven days a week with this amendment application, please revise the sentence that starts with "However, the landfill may extend…" to state "The waste acceptance hours for the facility will be 6:00 a.m. to 7:00 p.m., seven days a week."*

B. *If the facility intends to post waste acceptance hours on the site sign which will be more restrictive than the waste acceptance hours and days that are proposed to be authorized, as stated in the first sentence of the referenced Section, please revise the sentence by stating "The waste acceptance hours that will be posted on the site sign will be 7:00 a.m. to 4:00 p.m., six days a week."*

C. *For clarity, please consider revising the order of the sentences (i.e. first stating the waste acceptance hours that will be authorized with this amendment and then stating the actual waste acceptance hours that will be posted on the site sign.)*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Section 4.9.3 has been updated for clarity.

In addition, the following comments were received from the TCEQ on October 17, 2012 via email.

1. *If the facility intends to keep the liner system consisting of 6" of caliche layer and geomembrane, please ensure to address the rule requirements for an alternative liner (Comment #41 of the 1st NOD) under 30 TAC Section 330.335.*

   The original submittal of the alternative liner consisting of 6-inches of caliche has been included in Appendix 3J, Attachment 2. This submittal provides the HELP and Multimed model analyses for the caliche liner and conforms to 30 TAC §330.335. The previous approval letter from the TNRCC (now TCEQ) has also been provided for reference. It should be noted that throughout this submittal, the previously approved caliche liner is referred to as the "prescriptive" liner and the new proposed alternative liner (with GCL) is referred to as the alternative liner.

2. *Please revise the specs for the leachate collection system sand layer to maintain a hydraulic conductivity of $1x10^{-2}$ cm/s or greater. Please ensure to update the drawing P3-29 (Liner Details) and the text provided on Appendix 3I accordingly.*

   The leachate collection system sand layer (or protective sand layer) has been designed with a hydraulic conductivity of $1x10^{-3}$ cm/sec. HELP modeling of this sand layer (provided in Appendix 3I, Attachment 1) confirm that the specified hydraulic conductivity ($1x10^{-3}$ cm/sec) is sufficient to prevent a buildup of leachate on top of the geomembrane liner. Results of the HELP model analyses for different operating conditions are summarized in Table 3I-2.

3. *Also, please provide an appropriate Drainage Layer in between the proposed erosion layer and geomembrane for the prescriptive final cover system or provide justification on why it is not necessary.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

As described in the response to Comment #39, based on the soil type needed to achieve a permeability of 5.8×10^{-3} cm/sec (as modeled in the HELP model and identified in Appendix 3P, Table 3P-1 testing requirements), the erosion layer will also serve as a drainage layer above the geomembrane. The internal friction angle of the sand to be used for the soil erosion layer (prescriptive) needs to be 31° to achieve a factor of safety of 1.5 for the slope stability analysis. Soils testing will be completed prior to construction to ensure that the internal friction angle of the sand is at least 31° to ensure the 1.5 factor of safety (as indicated in Appendix 3P, Table 3P-1). Published values for the internal friction angle of sand are 26° - 40° and should be readily obtainable from the material onsite.

4. *Please delete the provision to provide a final cover system "for the landfill area that do not include a synthetic bottom liner," as a piggyback liner system has been proposed for the unlined portions of the landfill.*

   There are portions of the Landfill area still existing that will receive the final cover profile without a synthetic bottom liner. These areas are identified on Drawing P3-28 and are the areas of the existing unlined landfill up to the start of the liner profile for the piggyback area. The area to receive the piggyback liner is approximately 78-acres.

Should you have any questions or required additional information during the review of this permit application, please contact me at (651) 994-8415 or fredric.j.doran@saic.com.

Sincerely,

SAIC Energy, Environment & Infrastructure, LLC

Fredric J. Doran, P.E.
Senior Environmental Engineer

c w/encl: Miguel Parra, City of El Paso
Scott R. Pasternak, SAIC

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

August 9, 2012

Chandra S. Yadav
Project Manager
Texas Commission on Environmental Quality, MC 124
P.O. Box 13087
Austin, TX 78711-3087

Subject: **Response to First Notice of Deficiency (NOD)**
McCombs Municipal Landfill – El Paso County
Municipal Solid Waste (MSW) Permit No. 729B

Dear Mr. Yadav:

On behalf of the City of El Paso, SAIC Energy, Environment & Infrastructure, LLC (SAIC) is providing the information requested by the Texas Commission on Environmental Quality (TCEQ) first technical notice of deficiency (NOD) letter received March 19, 2012. A time extension request was granted by the TCEQ for an additional 90 days to the original due date for submittal by August 10, 2012. The TCEQ comment is provided in *italic print* followed immediately by the response. Revised sections and appendices are included as an attachment to this letter and are identified as to the appropriate replacement location in the existing application. It should be noted that the attachment is ordered as to the location of replacement in the existing application, not based on the order of comments.

The following Comments were provided by Mr. Chandra S. Yadav of the TCEQ:

1. *The application contains references to the existing permit (MSW Permit No. 729A) in several discussions and narratives (e.g., Part III, Section 3.3.2 for the permit modification dated April 24, 2002; Appendix 3B for the permit modification dated July 2009; Appendix 3J for the liner quality control plan dated August 7, 2002, etc.). If this permit amendment application is approved, will replace Permit No. 729A documents, and therefore, the permit amendment application for 729B must be a full permit application that contains all documents/information as required by the applicable rules without any reference to the Permit No. 729A. Please update the application as appropriate.*

   The above listed references (as well as others located) have been included in the Major Permit Amendment.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

2. *It appears that the following engineering documents are not provided with the responsible engineer's seal and signature in accordance with Texas Engineering Practice Act and Rules §137.33. Please ensure that the responsible engineer shall affix their seal and original signature or electronic seal and signature with the date on the final version of their engineering documents per rule requirements before such documents are released from their control.*

   a. traffic impact analysis in Appendix 2C;

   The TIA was completed and signed by the City of El Paso, an updated copy has been provided.

   b. soil loss calculations provided on Page 3B-1;

   Signed calculations have been provided.

   c. stormwater runoff, ditch sizing and culvert calculations provided in Appendix 3B, Attachments 1, 2 and 3 respectively;

   Signed calculations have been provided.

   d. pipe deflection calculations provided in Appendix 3I, Attachment 2;

   Signed calculations have been provided.

   e. Leachate and Contaminated Water Plan in Appendix 3I, Attachment 2; and

   A signed title page has been added to the Leachate and Contaminated Water Plan.

   f. Waste Mass Stability Report in Appendix 3G.

   The waste mass stability report is signed by AET on page ii of the report.

3. *The title pages of the submittal indicate "Technically Complete November 2011." Please remove such phrases from all the title pages.*

   The title pages have been updated and are provided in the Attachment.

Part I

4. *The title page indicates facility name as "McCombs Municipal Solid Waste Landfill", and Part I form indicates as "McCombs Municipal Landfill." Please ensure that the title page and Part I form indicate the correct name for the facility, and revise the pages as appropriate.*

   The title pages have been updated to be consistent with the Part I form and are provided in the Attachment.

5. *The metes and bounds description included in Section 1.4 (Appendix 1C) does not appear to identify the area specifically within the facility boundary, and is not signed and sealed by a registered professional land surveyor. Please address the rule requirements of 30 Texas*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Administrative Code (TAC) Section (§)330.59(d)(1) and (2), and resubmit the facility boundary metes and bounds description signed and sealed by a registered professional land surveyor. An area indicated in Drawing P3-17 is not included within the property boundary, please ensure that the metes and bounds description are included in the submittal. In addition, please ensure that the metes and bounds description for the easement area indicated in Drawing P3-17 is included in the submittal and explain why this easement area, which is owned by the city of El Paso is not proposed to be included in the area within the property boundary.

Updated Metes and Bounds surveys for both the permitted boundary and for the permitted boundary plus the Public Drop-off Area are provided in Appendix 1C.

6. *Please include a statement to ensure that all maps updated in the application are the latest revision in accordance with 30 TAC §330.59(c)(2).*

   The map sources used for the Drawings are provided in the notes to the drawings. The maps used to provide information were the latest version available at the time of map development.

Part II

7. *General location maps. Please provide the following information as required by 30 TAC §330.61(c) to accurately show proximity to surrounding features. Please also revise Section 2.3.1 to provide a narrative and to identify the location for the following information as appropriate.*

   Section 2.3.1 has been updated to provide the location and description of the below referenced items.

   a. *the prevailing wind direction with a wind rose;*

   The wind rose provided from the TCEQ is shown on Drawing P1-3 (Appendix 1A). The wind rose period of record is from 1984 to 1992. The wind rose frequency of occurrence of winds is plotted in the sixteen points of the compass, with a maximum of six wind speed classes for each direction.

   b. *all structures and inhabitable buildings within 500 feet of the proposed facility;*

   Three buildings were identified within a 500-foot radius of the facility boundary. These buildings include the CEMEX Quarry office and scale house and site trailers.

   c. *schools, licensed day-care facilities, churches, hospitals, cemeteries, ponds, lakes, and residential, commercial, and recreational areas within one mile of the facility;*

   Drawing P2-3 provides a land use map for the Landfill within one mile of the facility. Residential, commercial, and recreational areas are shown within this boundary. Table 2.4B-1 also provides a breakdown of the areas within the one mile radius by land use. Additionally, as

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

stated, there are no schools, licensed day-care facilities, churches, hospitals, cemeteries, or lakes within one mile of the Landfill. One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.

d. the location and surface type of all roads within one mile of the facility that will normally be used by the owner or operator for entering or leaving the facility;

The three main roads to be used by the facility (McCombs St, Stan Roberts Sr. Ave, and State Line Drive; locations shown on Drawing P2-1) are two-lane asphalt paved roads.

e. latitudes and longitudes;

The latitudes and longitudes of the facility are provided on Drawings P2-1 and P2-2.

f. area streams;

There were not any streams identified within a 1-mile radius of the facility.

g. drainage, pipeline, and utility easements within or adjacent to the facility;

Facility easements are provided on Drawing P2-7 and are also discussed in Section 4.9.6.

h. facility access control features;…

Access to the Landfill is restricted by an existing barbed wire fence located along the perimeter of the facility as well as a locking gate at the facility entrance as depicted on Drawing P2-7 and as described in Section 3.2.1.

…and archaeological sites, historical sites, and sites with exceptional aesthetic qualities adjacent to the facility.

As stated in Appendix 2B – Land Use Analysis, Page 2B-3, no archaeologically significant sites, historical sites, or locations of exceptional aesthetic quality were located within one-mile of the Landfill.

8. *Facility layout maps. Please revise the narrative in Section 2.3.2 to identify the maps that provide the information as required by 30 TAC §330.61(d)(1) through (9). It appears that the provided drawings do not indicate the interior facility roadways to provide access to fill areas and dimensions of landfill units/cells. Please include the interior facility roadways and dimensions of landfill units/cells in the facility layout drawings. Please also provide the following information as appropriate.*

Drawings P2-9 through P2-18 have been updated to indicate the potential interior facility roadways and dimensions of landfill units/cells.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

a. provisions for the maintenance of any natural windbreaks, such as greenbelts, where they will improve the appearance and operation of the facility and, where appropriate, plans for screening the facility from public view;

As described in Section 3.2.1, existing earthen berms along the western and northern boundaries of the Landfill provide a method of visual screening for the facility. This discussion has been included in Section 2.3.2.

b. sectors with appropriate notations to communicate the types of wastes to be disposed of in individual sectors; and

The type of waste to be received within each Sector has been updated on Drawings P2-9 through P2-18.

c. maximum waste elevations and final cover.

Maximum elevations for cell development are provided on Drawings P2-9 through P2-18. The actual waste elevation will be dependent on the final cover profile utilized (i.e., prescriptive or alternative final cover), but will generally be 40 or 48-inches lower than the final contour elevations (final cover profiles provided in Drawings P3-35 and P3-36) for prescriptive or alternative final cover, respectively.

9. *Drawing P3-17 indicates an entrance, a scale house, a public drop-off site, an above-ground fuel storage tank, an equipment maintenance building, and employee and public parking areas on the proposed easement area. But, the easement area and these features are not indicated on other appropriate drawings including the site layout plan. Please provide narrative to explain these features in the appropriate sections of the permit amendment application, and revise appropriate drawings, including the site layout plan.*

   The future site drawings have been updated to depict the entrance expansion area and the expansion area facilities are described in Section 3.2 and Section 4.1.

10. *Existing conditions summary. Please address the rule requirements of 30 TAC §330.61(a) that the owner or operator shall determine and report to the executive director any site-specific conditions that require special design considerations and possible mitigation of conditions identified in subsections §330.61 (h) - (o). The owner or operator may discuss any additional land-use, environmental, or special issues in an existing conditions summary.*

    Site specific conditions are summarized in Section 2.1.3. There are no existing site-specific conditions that require special design considerations or possible mitigation of conditions.

11. *The provided Flood Insurance Rate Map (FIRM) shows that some portions of the facility are in flood-prone areas that are inundated by the 100-year flood. Please provide information to*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

ensure that the waste disposal areas will be protected from the 100-year flood event. Please make sure to include engineering details, including cross-sections with freeboard information, for the floodplain mitigation structures. Please note that all berms/levees design to prevent the 100-year flood event should have a freeboard of at least three feet in accordance with 30 TAC §330.307(b)(1).

As discussed in Section 2.9.1, a portion of the Landfill is located within the 100-year floodplain. No waste disposal activities will occur in the section of the property lying within the 100-year floodplain. Furthermore, as discussed in the referenced Section 3.3.2, the proposed Landfill development base elevations are above the base flood elevations (BFE's). Pond A was sized to contain the volume of runoff plus a 25% emergency capacity and silt accumulations thus minimizing the impact to the BFEs for the area. Cross sections for Pond A are provided in Drawing P3-8. Note from the high-water elevation provided on the cross sections, at least three feet of freeboard is provided. The Pond A berm height is also above the 100-year flood elevation.

12. *Please explain why the Flood Insurance Map included as Drawings P2-26 and P3-13 is identified as "Preliminary". Please ensure that the FIRM provided on Drawing P2-26 and P3-13 is the latest revision of the map. 30 TAC §330.59(c)(2) requires that all maps provided in the application must be the latest revision.*

    At the time of development of the drawings, the Preliminary Flood Insurance Rate Maps (FIRM) were provided on the City of El Paso website (http://www.elpasotexas.gov/engineering/floodzones.asp). Since that time, the Federal Emergency Management Agency (FEMA) has "officially placed the preliminary flood insurance rate map project for El Paso County on hold until future notice". The FIRM from June 15, 1988 has been provided in the Attachment as a replacement to Drawings P2-26 and P3-13. It should be noted that there was not any apparent changes between the 1988 FIRM and the proposed FIRM map for the McCombs Landfill area, and the 100-year floodplain extents delineated on other drawings within the permit modification are still relevant.

13. *The provided copy of the National Pollution Discharge Elimination System, Storm Water Multi-Sector General Permit appears to be dated June 22, 1998. Please provide the current information demonstrating how the facility will comply with applicable Texas Pollutant Discharge Elimination System (TPDES) storm water permitting requirements and the Clean Water Act, 402, as amended. In accordance with 30 TAC §330.61(k)(3), the facility may provide a certification statement indicating that the owner/operator will obtain the appropriate TPDES permit coverage when required; or a copy of the permit number for coverage under an individual wastewater permit.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

As identified in Section 2.1.2, the Landfill currently holds a Texas Pollutant Discharge Elimination System (TPDES) Stormwater Permit (No. TXR05L795). Section 2.7.2 has been updated to include this permit number and an updated copy of the permit is provided in Appendix 2D.

Part III

14. *Please note, 30 TAC §305.45 requires a supplementary technical report submitted with an application. The report shall be prepared either by a Texas licensed professional engineer, a Texas licensed professional geoscientist, or by a qualified person who is competent and experienced in the field to which the application relates and thoroughly familiar with the operation or project for which the application is made. The report must include the following:*

    a. *a general description of the facilities and systems used for or in connection with the collection, transportation, treatment, and disposal of waste;*

    b. *for each place of disposal:*

        i) *the volume and rate of disposal of the defined waste, including appropriate averages, the maximum rates of disposal over representative periods of time, and detailed information regarding patterns of disposal; and*

        ii) *the physical, chemical, and radiological properties of the defined waste; the characteristics of the waste; the chemical, physical, thermal, organic, bacteriological, or radiological properties or characteristics, as applicable, described in enough detail to allow evaluation of the water and environmental quality considerations involved.*

    The supplementary technical report is included in Section 1.1.2 of the permit modification and has been updated to address the rule requirements.

15. *Please address the rule requirements of 30 TAC Chapter 330, Subchapter M: Location Restrictions, as applicable to the facility. Also, please provide a statement if any rules are not applicable to the facility. It is recommended to include the required information as appropriate in Part III of the application.*

    The rule requirements of 30 TAC §330, Subchapter M are identified and locations or addressed rules are provided below.

    - 30 TAC §330.543 - Easements and Buffer Zones
        - In accordance to 30 TAC §330.543(a), no solid waste unloading, storage, disposal, or processing operations will occur within any easement, buffer zone, or right-of-way that crosses the facility. The easements are identified on Drawing P2-7 and are discussed in further detail in Section 4.9.6.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

- In accordance to 30 TAC §330.543(b)(2)(B)(D), the vertical expansion utilized a 125-foot buffer zone for the newly permitted airspace. Discussion is provided in Section 4.9.6.

- 30 TAC §330.545 - Airport Safety
  - Airport safety is addressed in Section 2.5.2.
- 30 TAC §330.547 - Floodplains
  - Floodplains are addressed in Section 2.9.1.
- 30 TAC §330.549 - Groundwater
  - Groundwater conditions at the site are described in Section 2.7.1. However, 30 TAC §330.549 does not apply as additional groundwater evaluation is not required for the proposed vertical expansion of this facility.
- 30 TAC §330.551 - Endangered or Threatened Species
  - Section 2.10 addresses endangered species.
- 30 TAC §330.553 – Wetlands
  - Wetlands are addressed in Section 2.9.2. However, 30 TAC §330.553 does not apply as additional wetland evaluation is not required for the proposed vertical expansion of this facility.
- 30 TAC §330.555 - Fault Areas
  - Fault areas are discussed in Section 2.6.4. However, 30 TAC §330.555 does not apply as additional fault area evaluation is not required for the proposed vertical expansion of this facility.
- 30 TAC §330.557 - Seismic Impact Zones
  - Seismic impact zones are discussed in Section 2.6.5. However, 30 TAC §330.557 does not apply as additional seismic impacts zone evaluation is not required for the proposed vertical expansion of this facility.
- 30 TAC §330.559 - Unstable areas
  - Unstable areas are addressed in Section 2.6.6.
- 30 TAC §330.561 - Coastal Areas is not applicable to this facility.
- 30 TAC §330.563 - Type I and IV Landfill Permit Issuance Prohibited

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

- 30 TAC §330.563 does not apply to vertical expansions of landfills.

16. *Section "Bulky Items Storage" on Page 3.2-2 indicates that the large items will be stored at the referenced landfill until transported off-site. Please indicate a location where these items will be placed, and revise Drawings P3-2 and P3-17 as appropriate. Please ensure to provide schematic view drawings showing the various phases of collection, separation, and disposal as applicable for the types of wastes received at the facility including for the bulky items storage area as required by 30 TAC §330.63(b)(2)(B). Please revise the drawings as appropriate.*

    Drawing P3-17 has been updated to show bulky item storage locations within the public drop-off area.

17. *Section 3.2.2.1 on Page 3.2-2 indicates that the unloading area will include roll-off containers. However, the locations for roll-off containers are not indicated in the provided Drawing P3-2. Also, Drawing P3-2 does not appear to include generalized construction details for Public Drop-Off Area and it's cross-sectional details in accordance with 30 TAC §§330.63(b)(2)(D) and (E). Please provide a revised drawing.*

    Drawing P3-2 is meant to show the current conditions of the facility, and as the new facilities and entrance road have yet to be constructed, it is included in Drawing P3-17 (as referenced on Drawing P3-2, Note 5). The roll-off containers will be located in the z-depressions of the Public Drop-Off Site (and are called out on the updated Drawing P3-17 provided in the Attachment).

18. *Please identify all storage and processing components, and all loading and unloading areas (e. g. the public drop-off area, bulky items storage area, etc.) to provide a generalized process design and working plan for the facility. As required by 30 TAC §330.63(b)(2)(F), please provide locations and engineering design details of all containment dikes or walls (with indicated freeboard) proposed to enclose all storage and processing components and all loading and unloading areas. Please also revise appropriate drawings and Sections 3.2.2 and 3.2.3 accordingly.*

    The storage and processing components outside of the landfill disposal area are identified on Drawing P3-17. These include the public drop-off area and bulky items storage. Drawing C13 from the Moreno Cardenas submittal for the site development improvements has been included in Appendix 3E. The drawing indicates the ponding areas for the site entrance facilities as well as the high water elevations and top elevations of the containment ponds.

19. *It is stated in the fourth paragraph in Section 3.3.1.2 that the stormwater runoff is collected in a v-ditch around the perimeter of the landfill units. But, it appears (Drawing P3-4) that the v-ditch is provided only for some portions of the perimeter at the landfill. Please explain how the run-on (around the perimeter of the landfill) and run-off (especially from the existing conditions*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

drainage area, EX-3) are managed currently, and also identify the locations of the v-ditch on the drawing with legible legend information. Please ensure to address the rule requirements of 30 TAC §330.303(a) that a facility must be constructed, maintained, and operated to manage run-on and runoff during the peak discharge of a 25-year rainfall event and must prevent the off-site discharge of waste.

The statement provided in Section 3.3.1.2 is correct; the v-ditch collects stormwater around the perimeter of the existing landfill units and directs the stormwater into an existing stormwater pond. Drawing P3-4 has been updated to clearly show the v-ditch location around the existing facility and is provided in the Attachment. The facility will be constructed, maintained, and operated to ensure that run-on and runoff during the 25-year storm event is controlled within the site. This statement, as well as additional discussion of the stormwater run-on and runoff, has been added in Section 3.3.

20. *The permit boundary, and drainage area boundary lines/attributes on most drawings are overlapped, and form a solid line which makes it difficult to determine the actual permit boundary. Please revise these drawings including Drawing P3-4 to make sure that the permit boundary is clearly shown.*

    Due to the amount of different boundaries portrayed on each drawing, the predominant feature of the drawing was highlighted to be clear as to the intent and purpose of the drawing. Drawing P3-2 was developed to more clearly show the defined existing limits and boundaries of the facility and highlights the property boundary as well as the corner extents of the property (i.e., northing and easting). As to continue to clearly show the drainage areas on the stormwater drawings (i.e., P3-4), the drawings have not been updated.

21. *Please ensure to provide appropriate legend information on the drawings, including on Drawing P3-4 for the permit boundary and for the mined pit areas as referenced in the narrative provided in the fourth paragraph of Section 3.3.1.2. Please revise the drawing as appropriate.*

    Drawing legends for the entire drawing set are provided following the table of contents for each Part (Drawing P0-2). The current mined pit low areas are identified on Drawing P3-4 by the directional flow arrows. The majority of the site was originally a gravel mining pit; therefore specific areas are not delineated within the site. Current topography is provided in the background of the drawings to indicate high and low elevation areas.

22. *Please explain how the runoff being captured by the mined pit areas will continue during interim phase of landfill operation. Also, the last paragraph in Section 3.3.1.3 indicates that the landfill retains the stormwater onsite as well as receives some off-site run-on from the east. Please demonstrate that the runoff from the existing onsite drainage areas (EX-1, EX-2, EX-3), and run-on from the off-site areas will be provided with necessary drainage collection, conveyance, and*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

detention structures during all phases of landfill operation so that the existing or permitted drainage patterns will not be adversely altered in accordance with 30 TAC §330.305(a).

The mined pit areas will act as a sedimentation basin during interim phases of landfill operation. As each Sector is developed, delineation berms will be placed around the current sector to prevent runoff from the working face and run-on from the surrounding features. All drainage calculations for the facility (both existing and future conditions) include the additional run-on from these off-site areas. The site drainage collection, conveyance, and detention structures are designed to operate during all phases of landfill construction so that the existing drainage patterns will not be adversely altered in accordance with 30 TAC §330.305(a). Stormwater calculations are provided in Appendix 3B, Attachment 7 – Drainage Calculations.

23. *Appendix 3I, Attachment 3 (Leachate and Contaminated Water Plan) appears to be a copy of the document prepared by the engineer on August 7, 2002 for the existing permit (MSW Permit 729A). Please ensure that the headers and footers are updated to indicate the appropriate permit number, consulting firm's name, and page number on the document. Please ensure to address the rule requirements of 30 TAC §330.305(b) and (c) that the owner or operator shall design, construct, and maintain a run-on control system capable of preventing flow onto the active portion of the landfill during the peak discharge from at least a 25-year rainfall event, and a runoff management system from the active portion of the landfill to collect and control at least the water volume resulting from a 24-hour, 25-year storm. Please submit the updated calculations with the responsible engineer's seal and signature.*

    Appendix 3I, Attachment 3 was developed by Raba-Kistner Consultants, Inc for MSW Permit No. 729A on April 24, 2002 (Revised July 29, 2002). The assumptions utilized in the Leachate and Contaminated Water Plan prepared by Raba-Kistner comply with the 30 TAC §330.305(b) and (c) and are still relevant for the site operating conditions. These calculations have not been updated; however, a memo has been included to better describe the contents of Appendix 3I, Attachment 3.

24. *The final cover plan (Drawing P3-33) indicates the top slopes with 7% and the side slopes with about 33.33%. Please provide an estimate for peak velocities at the top surfaces and external embankment slopes for the final and interim conditions, and ensure that the estimated peak velocities for top surfaces and external embankment slopes will be less than the permissible non-erodible velocities under similar conditions in accordance with 30 TAC §330.305(d)(1).*

    Appendix 3B.4 has been added to address non-erodible velocities as per 30 TAC §330.305(d)(1).

25. *Appendix 3B in Attachment 5 indicates that the previously approved permit modification explains values of "R, K, S, C and P" used in the soil loss calculations. Please include the referenced information into the current application to explain the soil loss calculations as*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

appropriate. Please explain the soil loss calculations, including the length of slope used in the calculations provided on Page 3B-1.

The referenced values for R, K, S, C, and P from the MSW Permit No. 729A prepared by Parkhill, Smith and Cooper, Inc. (revision 2 July 2009) have been included in the Attachment. The soil loss calculations were performed using the Revised Universal Soil Loss Equation (RUSLE) as provided by the National Resource Conservation Service (NRCE), El Paso office (described in Appendix 3B.3). The maximum top dome length is 1,158 ft (DEV-5) and the maximum side slope length is 759 ft is (DEV-1). Soil loss calculations have been updated to provide additional information.

26. *It appears that the provided soil loss calculations are for the final conditions at the landfill for a single slope length of 750 feet. It does not appear that the provided soil loss calculations include calculations for the interim phases of landfill operation. In accordance with 30 TAC §330.305(d)(2), the top surfaces and external embankment slopes of municipal solid waste landfill units must be designed to minimize erosion and soil loss through the use of appropriate side slopes, vegetation, and other structural and nonstructural controls during all phases of landfill operation. Please revise the soil loss calculations as appropriate.*

    Soil loss calculations have been updated and are provided in Appendix 3B, Attachment 5.

27. *Appendix 3B, Section 3B.2 indicates that structural controls may include berms, dikes, swales, and rip-rap, however their design details and specifications are not provided. Please provide engineering designs, cross sectional details, and specifications for the drainage structures to be constructed during the interim and the final phases of the landfill development. Please note, 30 TAC §330.305(e) requires that dikes, embankments, drainage structures, or diversion channels must be sized and graded to handle the design runoff. The slopes of the sides and toe must be graded to minimize the potential for erosion. The surface water protection and erosion control practices must maintain low non-erodible velocities, minimize soil erosion losses below permissible levels, and provide long-term, low maintenance geotechnical stability to the final cover. Please revise the application as appropriate.*

    Design details and specifications for structural controls (i.e., silt fence, earthen diversion berms and dikes, drainage swales, and rip-rap) are addressed in the Erosion and Sediment Control Plan developed by Parkhill, Smith and Cooper (revision 2 July 2009) and has been included in Appendix 3B, Attachment 6. Drainage structures and diversion channels are not proposed for the final cover design as calculated soil erosion are less than the permissible soil loss and calculated velocities are below the permissible non-erosion velocities. Soil loss equations are provided as Appendix 3B.3 and non-erodible velocities for all phases of construction are provided as Appendix 3B.4.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

28. *Please address the rule requirements of 30 TAC §330.305(e)(a) and (b) that the owner or operator shall maintain the collection, drainage, and/or storage units as designed, and shall restore and repair the drainage system in the event of washout or failure, and control erosion and sedimentation, including having interim controls for phased development.*

    The rule requirements have been addressed in Appendix 3B.2.

29. *Section 3B.2.2 and Drawing P3-11 indicate that the ditches having velocities that exceed four feet per second will be protected against erosion. Also, the cross sectional drawings for the proposed ditches are not provided. Please explain how the value for the permissible velocity has been determined, and provide drawings with cross sectional details of ditches.*

    As stated in Section 3.3.1.3, ditches with velocities exceeding 4.0 feet per second will require erosion protection, according to maximum non-erodible velocities as published in the USDA-SCS Engineering Field Manual. This statement has been added to Appendix 3B.2.2 for clarification. Cross-sectional drawings for the proposed ditches have been provided within Appendix 3B, Attachment 2.

30. *It is stated in Section 3B.2.2 that the temporary and intermediate controls will be implemented for erosion and sedimentation management throughout the entire phasing of construction. However, details of control measures to be implemented for an erosion controls during interim phases of construction are not provided. It is recommended to follow the guidance documents "Guidance for Addressing Erosional Stability during All Phases of Landfill Operation" and "Outline of Requirements of The Erosion and Sediment Control (ESC) Measures for Landfill Facilities" to prepare an ESC Plan to address the rule requirements of 30 TAC §330.305. The guidance documents may be located on our website at the following internet address: http://www.tceq.state.tx.us/assets/public/permitting/waste/msw/interimdrainageguide.pdf*

    The "Guidance for Addressing Erosional Stability during All Phases of Landfill Operation" is a draft guidance document that should be followed in the development of an Erosion and Sediment Control plan. The second referenced document ("Outline of Requirements of The Erosion and Sediment Control (ESC) Measures for Landfill Facilities") is obsolete. Appendix 3B was updated to comply with the guidance document.

31. *Please address the rule requirements of 30 TAC §330.305 (g) that the owner or operator shall handle, store, treat, and dispose of surface or groundwater that has become contaminated by contact with the working face of the landfill or with leachate in accordance with 30 TAC §330.207 (relating to Contaminated Water Management). Storage areas for this contaminated water must be designed with regard to size, locations, and methods. Please also revise Section 3.2.3 as appropriate.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Contaminated Water Management is addressed in Appendix 3I.3 and Appendix 3I Attachment 3.

32. *Please provide a statement that the facility design complies with the requirements of 30 TAC §330.303 (relating to Surface Water Drainage for Municipal Solid Waste Facilities).*

    This statement has been added to Section 3.3.3.

33. *The cross sectional details, ditch grades and flowline elevations of the ditch are not provided in the submittal. In accordance with 30 TAC §330.63(c)(1)(B), please provide drawings to include designs of all drainage facilities within the facility area, including such features as typical cross-sectional areas, ditch grades, flow rates, water surface elevation, velocities, and flowline elevations along the entire length of the ditch.*

    As provided in the response to Comment 29, cross-sectional drawings (indicating slopes, design depths, and dimensions) for the proposed ditches have been provided within Appendix 3B Attachment 2. Design velocities are also included in the channel calculations.

34. *Please provide sample calculations to verify that existing drainage patterns will not be adversely altered in accordance with 30 TAC §330.63(c)(1)(C).*

    The overall site drainage boundary is not altered between existing and final conditions. For both the existing and final drainage conditions, no water leaves the site in the 100-year, 24-hour storm event. Calculations for the existing and final drainage conditions have been provided as Appendix 3B, Attachment 7 – Drainage Calculations.

35. *Structural design details for collection and conveyance systems for the runoff water along the top and side slopes are not provided. Please provide hydraulic calculations and designs for sizing the necessary collection and conveyance systems (e.g. berm, dike, chute, etc.), and identify their locations on appropriate drawings in accordance with 30 TAC §330.63(c)(1)(D)(iv). Please revise the drawings as appropriate.*

    Calculations for soil loss and peak velocities have been completed in accordance with 30 TAC §330.305(d) and are provided in Appendix 3B, Attachments 5 and 7, respectively. The calculations for soil erosion show that the potential soil loss is less than the permissible soil loss. The calculations for the velocities show that the peak velocities are less than the permissible non-erodible velocities. Structural designs for collection and conveyance along the top and side slopes (i.e., berms, dikes, chutes) are not proposed for the final cover design.

36. *In accordance with 30 TAC §330.63(c)(2)(C), please provide information detailing the specific flooding levels and other events that impact the flood protection of the facility. Data should be that required by §301.33 - 301.36 of this title (relating to Preliminary Plans: Data to be Submitted, Criteria for Approval of Preliminary Plans; Additional Information; Plans to Bear*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Seal of Engineer). The owner or operator shall include cross-sections or elevations of landfill berms/levees shown tied into contours.

30 TAC §330.63(c)(2)(C) states that "if the site is located within the 100-year floodplain, provide information detailing the specific flooding levels and other events…that impact the flood protection of the facility." The only area of the facility that is located within the 100-year floodplain is the existing Pond A. No waste will be placed within the 100-year floodplain. This is further discussed in Section 3.3.2 – Flood Control and Analysis. Furthermore, cross sections of Pond A are provided in Drawing P3-8 and storage capacity calculations provided in Appendix 3B, Attachment 1 and 7. As indicated on the cross-section, the Pond A berm is higher than the 100-year BFEs.

37. *It appears that a retention pond and berms/levees were constructed to protect the facility from a 100-year frequency flood. Please include the information per the rule requirements of 30 TAC §330.63(c)(2)(D)(i)-(iv) for any construction in a floodplain, as applicable to the facility.*

    Retention Pond A was constructed under the facility permit 729A and was permitted under the previous rules and limited data exist for the construction of the floodplain. As the pond was already constructed (and no waste will be placed within the 100-year floodplain extents), no new information is pertinent to this request. The 100-year BFEs are indicated on Drawing P3-8.

38. *The provided rule citations in Sections 3.3.2 and 3.8 appear to be incorrect. Please ensure to provide the correct rule citations.*

    The sections have been updated with the correct rule citations.

39. *Please revise the provided landfill unit cross-sections (P3-19 through P3-24) to indicate maximum elevation of proposed fill, top of the wastes, gas vents or wells, and groundwater monitoring wells, plus the initial and static levels of any water encountered, in accordance with 30 TAC §330.63(d)(4)(E). Please also ensure to provide narrative in Section 3.4.1.5 as appropriate.*

    Groundwater monitoring well locations and maximum elevations for cell development are provided on Drawings P3-19 through P3-24. The actual waste elevation will be dependent on the final cover profile utilized (i.e., prescriptive or alternative final cover), but will generally be 40 or 48-inches lower than the final contour elevations (final cover profiles provided in Drawings P3-35 and P3-36) for prescriptive or alternative final cover, respectively. The drawings have been updated to include reference to other drawings for locations of gas vents or wells and the approximate water elevation. Section 3.4.1.5 has also been updated.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

40. *Please address the rule requirements of 30 TAC §330.63(d)(4)(F) to provide construction and design details of compacted perimeter or toe berms that are proposed in conjunction with aboveground (aerial-fill) waste disposal areas to be included in the fill cross-sections.*

    For design detail clarity, the cross-sectional view of the perimeter berm is provided as Detail 4 on Drawing P3-29.

41. *It appears that Appendix 3J has been provided to update (Pages 1 through 4) the existing liner quality control plan (MSW Permit No. 729A). Please submit a complete liner quality control plan to address the rule requirements of 30 TAC Chapter 330, Subchapter H: Liner System Design and Operation (30 TAC §330.331 through §330.341), including for the proposed piggy-back liner system as applicable for the facility. Also, please provide a statement if any rules are not applicable to the facility.*

    Rule requirements of 30 TAC §330.331 through §330.333 are addressed in Appendix 3I – Leachate and Contaminated Water Plan. The Proposed Alternative Liner discussion (in accordance with 30 TAC §330.335) is included in Appendix 3J with modeling results provided in Appendix 3I. Rule 30 TAC §330.337 does not apply to this facility. Rules 30 TAC §330.339 and §330.341 are addressed in Appendix 3J.

42. *It is stated in Section 3I.2.2 that the leachate collection system and piping must be designed to maintain "a minimum of 30-centimeteer"of leachate depth over the liner." Please revise the statement to state that a leachate collection system must be designed and constructed to maintain "less than a 30-centimeter" depth of leachate over the liner in accordance with 30 TAC §330.331(a)(2).*

    Appendix 3I.2.2 has been updated to reflect the statement above.

43. *Please discuss the calculations provided in Attachment 2 of Appendix 3I, and ensure that the rule requirements of 30 TAC §330.333(3)(A)-(G) are addressed. Please revise the narrative provided in Section 3I.2.2 to explain that the proposed leachate-collection and associated leachate-removal systems are provided with the pipe strength, pipe network spacing, collection sump materials and strength, drainage media performance, and demonstration that pipes and perforations will be resistant to clogging and can be cleaned.*

    Rule requirements of 30 TAC §330.333(3)(A)-(G) are addressed in Appendix 3I.2.2. This section has been updated to provide rule references throughout for easier identification of addressed rules.

44. *Please discuss the calculations provided in Appendix 3I, Attachment 2 to explain that the proposed leachate-collection and associated leachate-removal systems will be of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes,*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

waste cover materials, and by any equipment used at the landfill in accordance with 30 TAC §330.333(2). Please also revise the narrative in Section 3I.2.2 as appropriate.

Appendix 3I.2.2 has been updated to provide additional discussion on the equations provided in Appendix 3I, Attachment 2.

45. *Please note that the analysis of leachate generation should assume surface conditions that simulate the most infiltration for the available soil and vegetation cover type at the site, and the precipitation data used in the modeling is current and site-specific. The assumption of bare ground for "Help Modeling Methodology/Assumptions (Table 3I-1)" indicates maximum runoff and less infiltration. In accordance with 30 TAC §330.165(c), intermediate cover layers are expected to be vegetated within six months of installation, and therefore, assumption of bare ground for the system that will last for 20 years is inappropriate. Please ensure that the modeling performed is accurate and site specific.*

    Intermediate cover conditions were remodeled for poor grass ground cover (typical vegetative growth for the City of El Paso) and HELP model results are included in Appendix 3I, Attachment 1.

46. *Since a vertical expansion at the landfill has been proposed, please address the rule requirements of 30 TAC §330.333(2)&(3)(A)-(G) for the existing leachate-collection and associated leachate-removal systems in the existing Sector K at the landfill.*

    As per 30 TAC §330.333(3)(D) and (F), the leachate collection layer and spacing has been evaluated via the HELP model and model results are provided in Appendix 3I, Attachment 1. The minimum coefficient of permeability specified for Sector K construction (Phase I/II) meets the requirements specified in Appendix 3I.2.2. As per 30 TAC §330.333(2) and §330.333(3)(C),(E), and (G), pipe deflection calculations have been added to Appendix 3I, Attachment 2 to evaluate the existing leachate collection piping in Sector K. As per 30 TAC §330.333(3)(A) and (B), the leachate sump capacity has been evaluated and the estimated rate of leachate removal is discussed in Appendix 3I.2.2.

47. *The proposed alternative liner system for the vertical expansion over waste in existing Pre-Subtitle D areas at the site does not appear to meet regulatory requirements of the 30 TAC Chapter 330 rules. The planned piggy-back liner proposed to be constructed consists of 25-foot to 55-foot of construction and demolition (C&D) waste over the existing waste in the Pre-Subtitle D area before placement of the proposed liner system. This indicates placement of waste over existing waste in a Pre-Subtitle D area without installing an approved liner over the existing waste as required by rule provisions under 30 TAC §330.331. Please explain how the proposed configuration meets the rule.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

The C&D waste placed prior to placement of the proposed liner system will consist of Class 3 inert waste (including, but not limited to, rock, brick, glass, dirt, certain plastics, rubber, and similar materials that are not readily decomposable). Section 1.1.2 (Supplementary Technical Report) has been updated to include this discussion.

48. *Please identify the components of the proposed alternative liner system and label coefficient of permeability values for soils to be used for constructed liners on related drawings including on P3-27 and P3-29. The soils must have a coefficient of permeability less than or equal to 1 x 10E-7 cm/sec to be used in constructed liners in accordance with 30 TAC §330.339(c)(5)(E). Please revise the appropriate drawings.*

    Drawing P3-29 has been updated to include the coefficient of permeability values on the details. Furthermore, these values are provided in Section 3.4, Tables 3.4-1 to 3.4-4. Drawing P3-27 has not been updated, as coefficient of permeability values are not applicable to the details provided on that drawing.

49. *It appears that an alternative liner system has been proposed in the application. Please discuss that the proposed alternative liner designs for the landfill includes a leachate management system with a demonstration by computerized design modeling that the maximum contaminant levels detailed in §330.331 of this title (relating to Design Criteria), Table 1 will not be exceeded at the point of compliance. Please also elaborate the narrative to explain the results of the Help Model included in Appendix 3I, Attachment 1.*

    The alternative liner design proposed in this application (Detail 2 on Drawing P3-29) is the replacement of the 6-inches of caliche with a geosynthetic clay liner. The replacement is detailed in Appendix 3J and modeled is included in Appendix 3I (HELP modeling) and Appendix 3J (MultiMed Model).

50. *A leachate collection sump appears to be located on the existing waste/intermediate cover within the Pre-Subtitle D area. In accordance with 30 TAC §330.167, ponding of water over waste (in active portion or on closed landfill) regardless of its origin is not allowed. A large-scale detail drawing of the locations of the leachate sumps, sump elevations, as well as details of the configuration of the leachate collection pipe inlet into the sumps needs to be provided to demonstrate compliance with the above-referenced rule.*

    The detail specific to the sump located on top of the piggyback of the Pre-Subtitle D area has been provided on Drawing P3-32, Section C. Note that the liner over the pre-subtitle D area will prevent water from entering the existing waste; furthermore, the water collected within the sump will be pumped out as needed to prevent standing water within the sump.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

51. *Please discuss the results of the waste mass stability analyses provided in Table C-2,3 and 4 of the report prepared by American Engineering Testing, Inc. (AET) considering the proposed landfill configuration presented in Drawing P3-16.*

    The initial waste mass stability analysis completed by AET evaluates the deep-seated stability of the waste and analyzes potential circular and block failure along cross-sectional planes "A", "B", and "E" (as provided in Appendix 3F). Table C-2 provides the results of these analyses using peak strength values; Table C-3 results are from completing a limited sensitivity analysis by varying the strength parameters from base conditions (i.e., reducing cohesion and interface friction angles independently). Table C-4 provides a secondary stability analysis using assumed large displacement interface shear strengths. The factor of safety values provided for peak and large displacement conditions are acceptable based on published information.

52. *The AET report estimates that a settlement due to compression of the existing waste from the new overlying waste could reach to 17.6 feet at station 25+00 along Cross-Section B. Please discuss if the recommended geosynthetic reinforcement "geogrid" (with a minimum design tensile strength of 3,500 pounds per foot at an allowable stress of 5% or less over the 50 year design life) will be sufficient for the stability of the piggy-back liner system along such cross-sections at the landfill.*

    Additional settlement evaluation has been provided in the Report of Supplemental Geotechnical Evaluation completed by AET (and provided in Appendix 3G). In summary, the maximum tensile strain calculated for the piggyback liner system is 0.206%. Published information indicates that HDPE can generally be assumed to have a yield strain in excess of 12% and GCL can generally be assumed to have a yield strain of 1% to 10%. The geogrid will have an allowable strain of 5%. The calculated tensile strain should not adversely affect the piggyback liner materials.

53. *It appears that the AET report does not include analyses for potential failures of the proposed liner system, the proposed C&D waste mass, and existing waste mass. Also, the report does not appear to include the adequacy of anchor trench design system, stability of the underlying liner system, and stability of interim slopes. Please discuss if the provided stability analyses will be sufficient to ensure the overall stability during the interim phase, and for the final graded landfill at the maximum design height.*

    Additional discussion and calculations have been completed regarding waste mass stability and are included in Appendix 3G. Potential failures of the proposed liner system and C&D and MSW waste mass are provided in the Supplemental Geotechnical Evaluation completed by AET. Additionally, the supplemental report includes the stability of the underlying liner system and

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

stability of the interim slopes. Anchor trench design calculations as well as veneer stability of liner materials during construction have also been provided in Appendix 3G.

Waste mass stability was completed for interim slopes at a 3H:1V slope at a maximum length of 270 feet. The factor of safety using peak strength parameters was 2.64 (circular failure) and 2.42 (block failure). The factor of safety assuming large displacement strength parameters was 1.60 (circular failure) and 1.76 (block failure).

The stability analysis of the final cover system indicated that for the maximum calculated head on top of the LLDPE liner along 3H:1V side slopes (0.67-feet) and with seepage parallel to the liner, the calculated factor of safety is 1.33 and for gravity only conditions, the calculated factor of safety is 1.61.

54. *The AET report does not include settlement analyses for foundation soils. Please note, if the foundation soils settle excessively due to the additional waste overburden, the base liner system will be subjected to excessive tensile stress causing the geosynthetic liner to stretch beyond the allowable design strain. In addition, settlements of foundation soils may adversely affect the design grades of the existing leachate collection system in the existing Sector K. Therefore, the relationship between the additional piggy-back loading and foundation soils settlement needs to be evaluated. Please revise the submittal as appropriate.*

    Additional discussion and calculations have been completed regarding waste mass stability and are included in Appendix 3G. A settlement analysis for foundation soils has been included in the Supplemental Geotechnical Evaluation completed by AET. Results indicate that the foundation settlement is estimated to be less than one foot, and the strain is estimated to be 0.03% or less. This amount of settlement and strain should not adversely affect the existing HDPE liner.

55. *Please provide a final cover system so that a clay-rich soil cover layer consisting of a minimum of 18 inches of earthen material with a coefficient of permeability no greater than 1 x 10^{-5} cm/sec will be overlain by a synthetic membrane. Please revise the application as appropriate, including Section 3.8 and Drawing P3-34 (Final Cover Details).*

    The prescriptive final cover profile has been updated in Section 3.8 and Drawing P3-34 to reflect the above comment.

56. *Please describe methods and procedures to be used to install the final cover in accordance with 30 TAC §330.457(e)(1).*

    The methods and procedures are provided in Appendix 3P – Final Cover Quality Control Plan in accordance with 30 TAC §330.457(e)(1).

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

57. *Please revise Drawing P3-16 to provide the surface drainage features and the flood protection features for 100-year floodplain as required by 30 TAC §330.457(e)(5). Please also ensure to provide cross sectional details for any structural features to be constructed.*

    As discussed in the response to comment #35, the calculations for soil erosion show that the potential soil loss is less than the permissible soil loss and the calculations for the velocities show that the peak velocities are less than the permissible non-erodible velocities. Structural designs for collection and conveyance along the top and side slopes (i.e., berms, dikes, chutes) are not proposed for the final cover design. The 100-year floodplain location has been added to Drawing P3-6. Cross sectional details for Retention Pond A are provided on Drawing P3-8.

58. *Please revise Section 3.8.4 to address the rule requirements of 30 TAC §330.457(g) that the owner or operator shall submit a certified copy of the modified deed to the executive director and place a copy of the modified deed in the operating record within the specified time frame.*

    Section 3.8.4 has been updated to include this language.

59. *Please include a statement in Section 3.8.4 that the owner and operator shall submit to the executive director a certified copy of an "affidavit to the public" in accordance with the requirements of 30 TAC §330.19 and 30 TAC §330.457(g) (relating to Deed Recordation and Closure Requirements for Municipal Solid Waste Landfill Units that Receive Waste on or after October 9, 1993).*

    The language within Section 3.8.4 has been updated to clearly state the requirements of 30 TAC §330.457(g).

60. *Please note that the closure, post-closure, or corrective action cost estimate requirements apply to owners and operators of any municipal solid waste facility authorized under this chapter are required to have financial assurance. Please address the rule requirements of 30 TAC Chapter 330, Subchapter L: Closure, Post-Closure, and Corrective Action Cost Estimate (30 TAC §330.503, §330.507 and §330.509).*

    Closure cost estimates are provided in Section 3.8.6 and Appendix 3N, Attachment 3 in accordance with 30 TAC §330.503. Provisions for financial assurance have also been included in Appendix 3N, Attachment 3.

    Post-closure cost estimates are provided in Section 3.9.6 and Appendix 3O in accordance with 30 TAC §330.507. Provisions for financial assurance have been included in Appendix 3N, Attachment 3.

    The Landfill is not required to take corrective action under 30 TAC §330.415 as required by 30 TAC §330.509(a) and therefore is not required to establish a financial assurance fund for corrective action.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

The following comments are provided by Mr. Jason Wang, P.G., of the TCEQ:

Part II

61. *Section 2.3.2 Facility Layout Map – Location of Monitor Wells Map p2-7.0 indicated only 3 groundwater monitor wells MW-1, 2, and 3. Please propose additional monitor wells that will satisfy the 600 feet maximum spacing at the point of compliance in accordance with 30 TAC §330.403(a)(2).*

    The Landfill is currently in the process of determining the site specific groundwater characteristics. The Landfill installed two additional groundwater monitoring points last year (July 2011) and is in the process of completing a one-year monitoring and observation period to determine the predominant groundwater flow direction. Upon completion of the monitoring and observation period, the consulting engineer for that project will provide recommendations as to the future groundwater monitoring site development plan. Once the groundwater assessment is completed the groundwater monitoring system can be designed and provided to TCEQ for review.

62. *Section 2.8.1 Abandoned Oil and Water Wells – Please discuss if any of the existing water wells are located within the facility boundary.*

    There are no existing water wells located within the permitted boundary or the total area to be used for the Landfill.

Part III

Geology Report, Appendix 3K

63. *Section 3.5 Attachment 3, Borings – The soil boring information in the application is from 1983. The borings and the information they yielded may have been adequate for the existing landfill design at the time it was permitted; however, the application proposes excavation plans and depths, as shown in drawings P3-21.0 and P3-22.0, that are not part of the current permit. The original borings alone do not appear to be sufficient in number, distribution, and depth to meet current regulatory standards for characterizing a landfill site. Please review the requirements of 30 TAC §330.63(e)(4) and determine where supplemental borings may be needed to fulfill characterization needs and to comply with the current rule requirements. Please develop and provide an updated Soil Boring Plan for the site for our review and approval to meet the requirements of the referenced rule. Required additional borings and documentation of results should be completed and submitted with the response to this NOD letter or further review of the application will be suspended.*

    The base grades provided on Drawings P3-21 and P3-22 for the sectors that are not constructed were approved in the Permit No. 729A and under the previous rules. The Landfill is not

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

requesting an increase in the landfill depth from the previous approval nor a lateral expansion to the permitted waste footprint. As per discussions with the TCEQ, an updated geology report is not necessary.

64. *Section 3.5– Please resubmit the entire Geology Report in a format that can be reviewed in accordance with 30 TAC §330.63(e)(1) through §330.63(e)(5)(F). The 1993 geology report by SHB AGRA Inc. is outdated and does not contain sufficient information to be reviewed under the current regulations. The data submitted are not organized into appropriate sections and do not follow the Municipal Solid Waste Permits Technical Review Checklist structure as presented in other portions of the major amendment application. Many of the photocopy pages of the 1993 report are illegible. The maps and drawings must be updated and resubmitted to be consistent with other figures presented in the major amendment application. All new geology maps, boring logs, and drawings must be sealed by a professional geologist.*

    An updated Section 3.5 detailing the contents of the Geology Report in Appendix 3K has been provided.

    The 2-mile water well search was updated for the first technical NOD response and is provided in Appendix 3K, Attachment 2. The scanned quality of the documents is as they were located on the Texas Water Development Board (TWDB) Water Information Integration and Dissemination (WIID) database and are considered the best version available.

Landfill Gas Management Plan

65. *Section 3.7– Please add text to include a backup plan that describes actions to be taken if the main gas monitoring and control system breaks down or becomes ineffective. This backup plan will be a separate subsection than the maintenance procedures.*

    In the event that the gas monitoring and control system becomes ineffective, actions will be taken in accordance with Section 3.7.7 – Remediation Plan. In the event that the gas monitoring and control system breaks down, procedures to initiate repairs will be taken in accordance with Section 3.7.8.

Appendix 3L - Groundwater Sampling and Analysis Plan

66. *Please indicate the location of proposed Point of Compliance on Figure P3-36.0.*

    See response to item 61. Once the groundwater assessment is completed, the groundwater monitoring system can be designed and provided to TCEQ for review.

67. *Please submit an analysis of the most likely pathway(s) for pollutant migration in the event the primary barrier liner system is penetrated as required under 30 TAC §330.63(f)(3).*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

See response to item 61. Once the groundwater assessment is completed, the groundwater monitoring system can be designed and provided to TCEQ for review.

68. *Please submit a documented certification signed by a qualified groundwater scientist that the facility is in compliance with the groundwater monitoring requirements.*

See response to item 61. Once the groundwater assessment is completed, the groundwater monitoring system can be designed and provided to TCEQ for review.

69. *Please propose additional monitor wells to be installed at the Point of Compliance. The current monitor well locations indicated on Figure P3-36.0 do not satisfy the maximum distance of 600 feet between wells at the Point of Compliance.*

See response to item 61. Once the groundwater assessment is completed, the groundwater monitoring system can be designed and provided to TCEQ for review.

70. *Please submit a plan for the design of the monitoring system that includes a thorough characterization of the parameters listed in 30 TAC §330.403(e)(1).*

See response to item 61. Once the groundwater assessment is completed, the groundwater monitoring system can be designed and provided to TCEQ for review.

Appendix 3N – Use of Alternative Cap

71. *The plant coverage was assumed to be 10% when the vegetative cover is established. Please provide a more detailed discussion to justify that the water balance alternative final cover design provides equivalent protection from wind and water erosion as the erosion layer specified in 30 TAC §330.457(a)(3).*

Due to the air conditions at the Landfill, the vegetative cover was removed from the alternative cap profile and replaced with 4-inches of rock armor. The rock armor will consist of graded material to provide an interlocking frame in order to help slope stability and minimize surface water erosion.

72. *Please explain how the Potential Evapotranspiration (PET) is calculated. If the PET is based on real weather data, please explain how the values are derived from seasonal variations.*

Site specific data for PET are not available and a sine function was used to distribute the PET. PET values are summarized in Table 3N-4 and weather data utilized for the 30-year modeling period are provided in Appendix 3N, Attachment 1.

73. *Please explain how the Transpiration and Evaporation values are derived for different supportive layer simulations.*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Transpiration is calculated within the UNSAT-H model utilizing user provided "suction head values that define how the potential transpiration rate applied to a particular node is reduced" (UNSAT-H manual). The suction head values for the different soil parameters are provided in Table 3N-2. As shown in Table 3N-7, due to the lack of vegetation, the actual transpiration is zero for the 30-year model period.

Evaporation is calculated using "the PET concept. The user supplies…daily weather data, with which the code calculates daily PET values using the Penman equation. During each time step, the code attempts to apply the potential evaporation rate. If the soil surface dries to or above a user-defined matric potential limit, the time step is re-solved using a Dirichlet condition at the surface. In this situation, the surface potential is held constant at the matric potential limit and evaporation is set equal to the flux from below." (UNSAT-H manual). Weather data is provided in Appendix 3N, Attachment 1 and actual evaporation values for the UNSAT-H modeling are also provided in Table 3N-7.

74. *A mixture of Sideoats Grama, Blue Grama, Fourwing Saltbush, Sand Dropseed and Akali Sacaton is proposed to be used for the vegetative cap. The root penetration depth of 30 inches is expected. This would indicate root penetration into the intermediate cover. Please explain if this root depth is simulated in the model.*

    As described in response to comment #71, the vegetative cover was removed from the alternative cap modeling.

75. *Please clarify if the 12 inches of intermediate cover serves as a capillary break for the proposed ET cover. Please also provide the soil characteristics of the intermediate cover and explain if the 30 inches root depth will disrupt this capillary break.*

    As described in response to comment #71, the vegetative cover was removed from the alternative cap modeling; therefore the root depth will not disrupt the capillary break between the 18-inch erosion layer and 6-inch support layer.

76. *The UNSAT-H Model Summary Table seems to include 12 inches of intermediate cover as part of the ET cover in the titles. Please clarify if the simulations actually included the intermediate cover.*

    The intermediate cover is not part of the ET cover. The modeling of the alternative cap includes the 4-inch rock armor, 18-inch erosion layer and 6-inch support layer. The intermediate cover is part of the waste filling operations.

77. *Please specify the nodal spacing for the simulation from the surface to the bottom layer and justify the number of nodes used. Figure 1, Moisture Content Distribution, referenced UNSAT-H*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

results for the node information. This information has not been submitted in the major amendment application.

The input and output files for the UNSAT-H modeling have been provided. The nodal spacing utilized for the modeling is specified in Table 3N-1 (43 nodes).

78. *Please provide a table of input parameter summary for UNSAT H, in accordance with the user manual by Fayer (2000), with each parameter name, parameter description, range of values, and explanation of values used. This table should include options used, soil characteristics values, initial conditions, plant information, and boundary conditions.*

The summary of input parameters used for UNSAT-H modeling is provided as Table 3N-1.

79. *Please submit the model input and output files.*

UNSAT-H model input and output files have been included in Appendix 3N, Attachment 1.

80. *Tables 1-1 and 1-2 indicated extremely high saturated hydraulic conductivity values (25.8 cm/s and 20.5 cm/s). Please correct the units to match the values provided in the laboratory test results.*

All values have been updated to reflect the laboratory testing results provided in Appendix 3N, Attachment 2.

81. *Please submit soil water retention curves for 75%, 80%, and 85% compaction and their van Genuchten parameter values.*

Soil testing results have been provided in Appendix 3N, Attachment 2.

82. *Please submit graphs to represent moisture content versus hydraulic conductivity for 75%, 80%, and 85% compaction for the site soils.*

Soil testing results have been provided in Appendix 3N, Attachment 2.

83. *Please illustrate how the theoretical total water storage capacity of the proposed cover for the 12 inches topsoil vegetation layer and the 12 inches supportive layer is calculated.*

The moisture content varies greatly in the 18-inch erosion layer, demonstrating the movement of water due to the natural water cycle of precipitation, evaporation, transpiration and infiltration. In the lower level of the profile (6-inch support soil), moisture values remain fairly constant. This demonstrates the suitability of the material as an ET cover in providing water storage in the cap. Water storage values for each year end are summarized in Table 3N-7. These values are calculated via the UNSAT-H model.

84. *Please list the numerical value used for each layer for the following parameters in a table format: measured saturated water content; field capacity water content; wilting point water*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

content, volumetric storage capacity; and layer storage. These values must be based on laboratory measured values from actual site soil samples and not based on soil classification and assumed values from U.S. EPA HELP Model.

The summary of the UNSAT-H parameters for the soil layers are provided in Table 3N-3.

85. *Please submit construction diagrams of the proposed ET cover, side slope, drainage divergence berms, and tie-ins to the existing composite cover.*

Details of the proposed ET cover are provided on Drawing P3-35.

86. *Please submit a slope stability demonstration showing the detailed calculations on how the factor of safety is derived using soil laboratory data. Please also indicate whether the calculated factor of safety also represents the worst case scenario.*

Slope stability analysis for the alternative final cover has been completed and is included in Appendix 3G. The calculations were completed using the soil testing results included in Appendix 3N, Attachment 2. The factor of safety calculated for the alternative final cover is 1.41 with no water flow.

87. *Please submit an Alternative Final Cover Construction Quality Control Plan. Please see TCEQ Regulatory Guidance Document RG-494, Guidance for Requesting a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill, dated January, 2012.*

A Final Cover Construction Quality Control Plan (including alternative final cover) has been prepared and is included in Appendix 3P.

Part IV

88. *Section 4.9.3 Facility Hours – Please provide more specific language on the operating hours. The proposed text "However, the Landfill may extend the operating hours to within 6:00 a.m. to 7:00 p.m., seven days a week in accordance with the hours permitted for the Landfill" is unclear.*

The section has been updated to clarify this language. The Landfill typically accepts wastes from 7 am to 4 pm six days a week; however, the Landfill has the option to extend the waste acceptance hours to within the hours of 6 am to 7 pm seven days a week per the permitted hours for the Landfill.

89. *Section 4.9.4 Site Sign – The TCEQ permit number will be MSW 729B once the major amendment is issued. Please make the correction from MSW 729A.*

This section has been updated to include the correct reference.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

90. *Section 4.9.6 Easements and Buffer Zones – Please note that for vertical expansion, in accordance with 30 TAC §330.543(b)(2)(B), requires a 125-foot buffer zone instead of the proposed 50-foot minimum buffer zone. Please revise the proposed text.*

    The text has been revised to include the correct buffer zone language.

91. *Section 4.9.7 Landfill Markers and Benchmark – Please add text to reflect rule requirements under 30 TAC §330.143(b)(5) that intermediate markers for the grid system must be installed, where feasible.*

    The section has been updated to include reference to the rule.

92. *Section 4.9.7 Landfill Markers and Benchmark – Please add text to reflect rule requirements under 30 TAC §330.143(b)(6) that area markers will not be placed inside constructed soil liner or geomembrane area.*

    The section has been updated to include reference to the rule.

93. *Section 4.9.15 Landfill Gas Control – The landfill gas monitoring report form submitted in Appendix 4A listed GMP numbers that do not match the GMP numbers listed in Table 3.7-1 of the Landfill Gas Management Plan. Please make the necessary corrections to ensure consistency.*

    The form located within Appendix 4A have been updated to correctly list the landfill gas wells located onsite.

94. *Section 4.9.16 Oil, Gas and Water Wells – Please include language to reflect rule requirements under 30 TAC §330.161(a) that the notification of discovery of a water well within the facility boundary is submitted within 30 days of its discovery along with the well plugging certification.*

    The section has been updated to reflect the referenced rule.

95. *Section 4.9.18.3 Alternative Material Daily Cover – Please add text to include 30 TAC §330.165(d)(5) requirement that alternative daily cover must not exceed constituent limitations imposed on waste authorized to be disposed at the facility.*

    The section has been updated to reflect the referenced rule.

96. *Section 4.9.18.6 Erosion of Cover – Please add text to specify frequency of inspection of final cover and methods for documenting repairs in the cover inspection records.*

    The section has been updated to reflect 30 TAC §330.463(a)(1).

97. *Section 4.9.19 Ponded Water – Please explain how the water that has contacted waste and contaminated water will be disposed of properly. Please also explain how the water that may*

Subject: **Major Permit Amendment Administrative NOD**
McCombs Municipal Solid Waste Landfill Permit No. 729B

Dear Mr. Reese:

On behalf of the City of El Paso, SAIC Energy, Environment & Infrastructure, LLC (SAIC) is providing the information requested by the Texas Commission on Environmental Quality (TCEQ) administrative notice of deficiency (NOD) letter received December 22, 2011. The TCEQ comment is provided in *italic print* followed immediately by the response.

- *Please revise and resubmit the Title Pages to show the Municipal solid waste permit application number; the name of the owner and operator; the location by city and county the date the part was prepared; including a current Professional Engineers (P.E.) Seal on each page and, if appropriate, the number and date of the revision. 30 TAC 330.57 (g) (2). The permit application number should be written as 729B.*

  The updated Title Pages and Table of Contents are provided in Attachment 1. Please remove and replace the previously provided pages with the updated pages. Additionally, updated cover pages and side labels have been provided that show the correct application number for your convenience.

- *Please provide the name for the public place in the county where the facility is, or will be located for review and copying by the public and resubmit page 3 with the correct site location information.*

  The updated page 3 of the TCEQ-0650, Part I Application Form is provided in Attachment 2 (along with the entirety of the Part I Application Form). Please remove and replace the previously provided page 3 with the updated page 3.

- *Please provide publicly accessible internet Web site, the Web address link for the application materials. This internet posting is for informational purposes only.*

  The internet access website is the same as previously provided. The City has uploaded the Major Permit Amendment Application with the Revision 1 changes to this website.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

- *Please provide the name and mailing address for the current State Senator in the district in which the facility is or will be located. Either local district addresses or capital addresses are acceptable. Please review and resubmit page 5 with the correct information. 30 TAC §39.103(b).*

  The updated page 5 of the TCEQ-0650, Part I Application Form is provided in Attachment 2 (along with the entirety of the Part I Application Form). Please remove and replace the previously provided page 5 with the updated page 5.

- *Please submit the name of the individual who will be responsible for publishing newspaper notice to the public, include the complete mailing address, telephone number, and fax number. Please provide an e-mail address for that individual as well, if available. 30 TAC §39.501(c).*

  The individual responsible for publishing newspaper notice to the public has been provided in Attachment 3. Please add the additional information page to the major permit amendment application following the Part 1 Application Form.

- *Please submit the name and mailing address of the mayor and city health authority of the municipality in whose territorial limits or extraterritorial jurisdiction the facility is or will be located. In addition, please provide the name and mailing address of the county judge and the health authority of the county in which the facility is located, if applicable. 30 TAC §39.103(c).*

  The name and mailing address of the mayor, city health authority, and county judge have been provided in Attachment 3. The health authority of the county is appointed through the City; and therefore does not exist. Please add the additional information page to the major permit amendment application following the Part 1 Application Form.

- *Please submit an electronic copy of the names and addresses of the adjacent landowners only, in the proper format. It must be submitted on a separate CD using Microsoft Word processing software of a 100% compatible format containing* ***3 columns per page and 10 names per column****. Each name and address must be typed in the format that meets the United States Postal Service requirements for machine readability.* ***Each letter in the name and address much be capitalize, contain no punctuation, and the appropriate two-character abbreviation must be used for the state.*** *Alternatively you may submit* ***four complete set of pre-printed labels of this mailing list****. If you wish to provide the list on printed labels, please use sheets of labels that have 30 labels to a page, 3 columns per page and 10 names per column. Omit permit number and applicant's name on the top line when sending labels. 30 TAC §281.5, 30 TAC §330.59(c), (3)(B) and 30 TAC §305.-45(a)(6)(D); 281.5(6).*

  The mailing labels have been formatted as requested and are provided in Attachment 4 of the original document. Actual mailing labels are intentionally not provided in the three (3) application revision copies.

- *Please submit current documentation of coordination with the Texas Department of Transportation (TXDOT) for traffic and location restrictions. The letter should have a current date in context to the application date. A copy of your letter requesting the information from*

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

TXDOT is sufficient, at this time. When a response from the TXDOT is received, please forward a copy for inclusion into the permit application. 30 TAC §330.61(i)(4).

A copy of the letter submitted to the TxDOT has been provided in Attachment 5. Please add this letter to Appendix 2C of the major permit amendment application. It is important to note that the referenced Attachment 1 in the letter to the TxDOT has not been provided to the TCEQ as it contains the information already provided in Appendix 2C.

- *Please submit current documentation of coordination with the United States Fish and Wildlife Service and Texas Parks and Wildlife Department. The letter should have a current date in context to the application date. A copy of the applicant's cover letter to the Texas Parks and Wildlife Department and United States Fish and Wildlife Service requesting this evaluation is sufficient, at this time. When a response from the United States Fish and Wildlife Service and Texas Parks and Wildlife Department is received, please forward a copy for inclusion into the permit application. 30 TAC §330.61(n)(1)(2).*

  Copies of the letters submitted to the Texas Parks and Wildlife Department and the U.S. Fish and Wildlife Service have been provided in Attachment 6. Please add these letters to Appendix 2F of the major permit amendment application. It is important to note that the referenced Attachment 1 in the letters have not been provided to the TCEQ as they contain the information already provided in Appendix 2F. Additionally, Section 2.10 (Revision 1) has been updated to reflect this correspondence and is provided in Attachment 7. Please remove and replace the previously provided Section 2.10.

- *Please submit documentation of coordination with the Federal Aviation Administration for compliance with airport location restrictions. A copy of the applicant's cover letter to the Federal Aviation Administration requesting this evaluation is sufficient, at this time. 30 TAC §330.61(i)(5). & 30 TAC §330.545(a).*

  A copy of the letter submitted to the FAA has been provided in Attachment 5. Please add this letter to Appendix 2C of the major permit amendment application. Additionally, Section 2.5 (Revision 1) has been updated to reflect this correspondence and is provided in Attachment 8. Please remove and replace the previously provided Section 2.5.

- *Please resubmit map or maps of the facility which clearly shows the information specified in 30 TAC §330.57(h)(5). Specifically, north arrow, base map source, legends, dates, and P.E. Seal, if applicable.*

  The updated maps have been provided in Attachment 9. Please note that a general facility legend is provided as part of the TOC of each section as Drawing No. P0-2.0. Please remove and replace the previously provided maps with the updated maps as indicated.

- *Please submit a complete Core Data Form.*

  The updated Core Data Form is provided in Attachment 10. Please remove and replace the previously provided form with the updated pages.

SAIC

November 22, 2011

Texas Commission on Environmental Quality
Attention: Waste Permits Division, MC 126
P.O. Box 13087
Austin, Texas 78711-3087

Subject: **Major Permit Amendment**
McCombs Municipal Solid Waste Landfill Permit No. 729A

Dear Waste Permit Division:

On behalf of the City of El Paso, SAIC Energy, Environment and Infrastructure, LLC (SAIC) is submitting the original application plus three copies of the enclosed document entitled, "Major Permit Amendment, McCombs Municipal Solid Waste Landfill Permit No. 729A", prepared by SAIC, and dated November 2011. The application includes Parts I through IV as required by the Texas Commission on Environmental Quality (TCEQ). In addition, SAIC is providing the TCEQ with twelve (12) additional copies of Part I: General Information, of the application and a CD containing an electronic mailing list of the adjacent landowners.

The completed TCEQ Core Data Form and TCEQ Permit Application Form for Part I are provided immediately after this cover letter. Payment documentation can be located in the Part I, Section 1.8.

It should be noted that a signed approval letter from the Rio Grande Council of Governments (COG) will be provided upon receipt (anticipated in January 2012) and that the letter provided in Part II, Appendix 2H is a draft letter that was provided by the COG until a signed original is received.

Should you have any questions during the review of this permit application, please contact Fred Doran at (651) 994-8415 or fredric.j.doran@saic.com and/or Scott Pasternak at (512) 651-6405 or scott.r.pasternak@saic.com.

Sincerely,

SAIC Energy, Environment & Infrastructure, LLC

Application Type:

☐	Permit	☒	Major Amendment	☐	Minor Amendment
☐	Registration	☐	Modification	☐	Temporary Authorization
		☒	w/Public Notice		
		☐	w/out Public Notice	☐	Notice of Deficiency Response

[1] The operator has the duty to submit an application if the facility is owned by one person and operated by another [30 TAC 305.43(b)]. The permit will specify the operator and the owner who is listed on this application [Section 361.087 Texas Health and Safety Code].

Facility Classification:

☒	Type I	☐	Type IV	☐	Type V	☐	Type IX
☐	Type I AE	☐	Type IV AE	☐	Type VI		

Activities covered by this application (check all that apply):

☐	Storage	☐	Processing	☒	Disposal

Waste management units covered by this application (check all that apply):

☐	Containers	☐	Tanks	☐	Surface Impoundments	☒	Landfills
☐	Incinerators	☐	Composting	☐	Type IV Demonstration Unit	☐	Type IX Energy/Material Recovery
☐	Other (Specify)			☐	Other (Specify)		
☐	Other (Specify)			☐	Other (Specify)		

Is this submittal part of a Consolidated Permit Processing request, in accordance with 30 TAC Chapter 33?

☐ Yes ☒ No

If yes, state the other TCEQ program authorizations requested.

Provide a brief description of the portion of the facility covered by this application. For amendments, modifications, and temporary authorizations, provide a brief description of the exact changes to the permit or registration conditions and supporting documents referenced by the permit or registration. Also, provide an explanation of why the amendment, modification, or temporary authorization is requested.

This Major Permit Amendment application is for a vertical expansion to the existing McCombs Landfill owned and operated by the City of El Paso as well as a property size increase to 347-acres to account for the site entrance facilities. It should be noted that there is not an increase to the waste boundary. This amendment is requested to allow the City of El Paso to have adequate capacity for future solid waste disposal needs.

Does the application contain confidential Material? ☐ Yes ☒ No

If yes, cross-reference the confidential material *throughout the application* and submit as a separate document or binder conspicuously marked "CONFIDENTIAL."

Alternative Language Notice Instructions

For certain permit applications, public notice in an alternate language is required. If an elementary school or middle school nearest to the facility offers a bilingual program, notice may be required to be published in an alternative language. The Texas Education Code, upon which the TCEQ alternative language notice requirements are based, trigger a bilingual education program to apply to an entire school district should the requisite alternative language speaking student population exist. However, there may not exist any bilingual students at a particular school within a district which is required to offer the bilingual education program. For this reason, the requirement to publish notice in an alternative language is triggered if the nearest elementary or middle school, as a part of a larger school district, is required to make a bilingual education program available to qualifying students and either the school has students enrolled at such a program on-site, or has students who attend such a program at another location in satisfaction of the school's obligation to provide such a program as a member of a triggered district.

If it is determined that an alternative language notice is required, the applicant is responsible for ensuring that the publication in the alternate language is complete and accurate in that language. Electronic versions of the Spanish template examples are available from the TCEQ to help the applicant complete

the publication in the alternative language.

Alternative Language Notice Application Form:

Alternative language notice confirmation for this application:

1. Is a bilingual program required by the Texas Education Code in the school district where the facility is located? ☒ YES ☐ NO

   (If NO, alternative language notice publication not required)

2. If YES to question 1, are students enrolled in a bilingual education program at either the elementary school or the middle school nearest to the facility? ☒ YES ☐ NO

(IF YES to questions 1 and 2, alternative language publication is required; If NO to question 2, then consider the next question)

3. If YES to question 1, are there students enrolled at either the elementary school or the middle school nearest to the facility who attend a bilingual education program at another location? ☐ YES ☐ NO

(If Yes to questions 1 and 3, alternative language publication is required; If NO to question 3, then consider the next question)

4. If YES to question 1, would either the elementary school or the middle school nearest to the facility be required to provide a bilingual education program but for the fact that it secured a waiver from this requirement, as available under 19 TAC ' 89.1205(g)?
   ☐ YES ☐ NO

(If Yes to questions 1 and 4, alternative language publication is required; If NO to question 4, alternative language notice publication not required)

If a bilingual education program(s) is provided by either the elementary school or the middle school nearest to the facility, which language(s) is required by the bilingual program?

Note: Applicants for new permits and major amendments must make a copy of the administratively complete application available at a public place in the county where the facility is, or will be, located for review and copying by the public.

Public place where administratively complete permit application will be located.				
Public Place (e.g., public library, county court house, city hall, etc.):	El Paso Municipal Service Center (MSC)			
Mailing Address:	7968 San Paulo Dr.			
(City) (County)(State)(Zip Code):	El Paso	El Paso	TX	79907
(Area Code) Telephone Number:	915-621-6700			

B. Facility Location

Except for Type I AE and Type IV AE landfill facilities, for permits, registrations, amendments, and modifications requiring public notice, provide the URL address of a publicly accessible internet web site where the application and all revisions to that application will be posted.

☒ Albuquerque, NM	☐ Ft. Worth, TX	☐ Galveston, TX	☐ Tulsa, OK

C. Maps

General **(See Part I – Section 1.3)**

For permits, registrations, and amendments only, submit a topographic map, ownership map, county highway map, or a map prepared by a registered professional engineer or a registered surveyor which shows the facility and each of its intake and discharge structures and any other structure or location regarding the regulated facility and associated activities. Maps must be of material suitable for a permanent record, and shall be on sheets 8-1/2 inches by 14 inches or folded to that size, and shall be on a scale of not less than one inch equals one mile. The map shall depict the approximate boundaries of the tract of land owned or to be used by the applicant and shall extend at least one mile beyond the tract boundaries sufficient to show the following:

each well, spring, and surface water body or other water in the state within the map area;

the general character of the areas adjacent to the facility, including public roads, towns and the nature of development of adjacent lands such as residential, commercial, agricultural, recreational, undeveloped, etc;

the location of any waste disposal activities conducted on the tract not included in the application; and

the ownership of tracts of land adjacent to the facility and within a reasonable distance from the proposed point or points of discharge, deposit, injection, or other place of disposal or activity.

General location maps **(See Part I – Section 1.3)**

For permits, registrations, and amendments only, submit at least one general location map at a scale of one-half inch equals one mile. This map shall be all or a portion of a county map prepared by Texas Department of Transportation (TxDOT). If TxDOT publishes more detailed maps of the proposed facility area, the more detailed maps shall also be included in Part I. Use the latest revision of all maps.

Land ownership map **(See Part I – Section 1.3)**

Provide a map that locates the property owned by adjacent and potentially affected landowners. The maps should show all property ownership within 1/4 mile of the facility, on-site facility easement holders, and all mineral interest ownership under the facility.

Landowners list **(See Part I – Section 1.3)**

Provide the adjacent and potentially affected landowners' list, keyed to the land ownership map with each property owner's name and mailing address. The list shall include all property owners within 1/4 mile of the facility, easement holders, and all mineral interest ownership under the facility. Provide the property, easement holders', and mineral interest owners' names and mailing addresses derived from the real property appraisal records as listed on the date that the application is filed. Provide the list in electronic form, as well.

D. Property owner information

For permits, registrations, amendments, and modifications that change the legal description, a change in owner, or a change in operator only, provide the following:

(1) the legal description of the facility; **(See Part I – Section 1.4)**

- (A) the abstract number as maintained by the Texas General Land Office for the surveyed tract of land;
- (B) the legal description of the property and the county, book, and page number or other generally accepted identifying reference of the current ownership record;
- (C) for property that is platted, the county, book, and page number or other generally accepted identifying reference of the final plat record that includes the acreage encompassed in the application and a copy of the final plat, in addition to a written legal description;
- (D) a boundary metes and bounds description of the facility signed and sealed by a registered professional land surveyor;
- (E) on-site easements at the facility, and
- (F) drawings of the boundary metes and bounds description; and

(2) a property owner affidavit signed by the owner. **(See Part 9 of Part 1 Form 0650)**

E. Legal authority

Provide verification of the legal status of the owner and operator, such as a one-page certificate of incorporation issued by the secretary of state. List all persons having over a 20% ownership in the proposed facility. **(See Part I – Section 1.5)**

Indicate Ownership status of the facility:									
☐	Private	☐	Corporation	☐	Partnership	☐	Proprietorship	☐	Non-Profit Organization
☐	Public	☐	Federal	☐	Military	☐	State	☐	Regional
☐	County	☒	Municipal	☐	Other (Specify)				

Does the operator own the facility units and the facility property?	☒ Yes	☐ No

If "No," for permits, registrations, amendments, and modifications that changes the legal description, a change in owner, or a change in operators submit a copy of the lease for the use of or the option to buy the facility units or facility property, as appropriate, and identify:	
Owner Name:	
Street or P. O. Box:	
(City) (County)(State)(Zip Code):	
(Area Code) Telephone Number:	
(Area Code) FAX Number:	
Charter Number:	

F. Evidence of competency

For permits, registrations, amendments, and modifications that change the legal description, a change in owner, or a change in operators submit a list of all Texas solid waste sites that the owner and operator have owned or operated within the last ten years.

Site Name	Site Type	Permit/Reg. No.	County	Dates of Operation
See Part I – Section 1.6				

Submit a list of all solid waste sites in all states, territories, or countries in which the owner and operator have a direct financial interest.

Site Name	Location	Dates of Operation	Regulatory Agency (Name & Address)
See Part I – Section 1.6			

A licensed solid waste facility supervisor, as defined in 30 TAC Chapter 30, Occupational Licenses and Registrations will be employed before commencing facility operation.

Provide the names of the principals and supervisors of the owner's and operator's organization, together with previous affiliations with other organizations engaged in solid waste activities.

Name	Previous Affiliation	Other Organization
See Part I – Section 1.6		

For landfill permit applications only, evidence of competency to operate the facility shall also include landfilling and earthmoving experience if applicable, and other pertinent experience, or licenses as described in 30 TAC Chapter 30 possessed by key personnel. The number and size of each type of equipment to be dedicated to facility operation will be specified in greater detail on Part IV of the application within the site operating plan.

Landfilling/Earthmoving Equipment Types	Personnel Experience or Licenses
See Part I – Section 1.6	

For mobile liquid waste processing units, submit a list of all solid waste, liquid waste, or mobile waste units that the owner and operator have owned or operated within the past five years. Submit a list of any final enforcement orders, court judgments, consent decrees, and criminal convictions of this state and the federal government within the last five years relating to compliance with applicable legal requirements relating to the handling of solid or liquid waste under the jurisdiction of the commission or the United States Environmental Protection Agency. Applicable legal requirement means an environmental law, regulation, permit, order, consent decree, or other requirement.

Solid waste, liquid waste, or mobile waste units owned or operated within past 5 years	Texas and federal final enforcement orders, court judgments, consent decrees, and criminal convictions
Not Applicable	

G. Appointments

Provide documentation that the person signing the application meets the requirements of 30 TAC §305.44, Signatories to Applications. If the authority has been delegated, provide a copy of the document issued by the governing body of the owner or operator authorizing the person that signed the application to act as agent for the owner or operator. **(See Part I – Section 1.7)**

H. Application Fees

For a new permit, registration, amendment, modification, or temporary authorization, submit a $150 application fee. **(See Part I – Section 1.8)**

For authorization to construct an enclosed structure over an old, closed municipal solid waste landfill in accordance with 30 TAC 330 Subchapter T, submit a $2,500 application fee.

If paying by check, send payment to:

Texas Commission on Environmental Quality
Financial Administration Division, MC 214
P. O. Box 13087
Austin, Texas 78711-3087

Payment maybe made online using TCEQ e-pay at www.tceq.state.tx.us/e-services/	
E-pay confirmation number	582EA000111781

PROPERTY OWNER AFFIDAVIT

"I, Kurt Fenstermacher,
(property owner)
acknowledge that the State of Texas may hold me either jointly or severally responsible for the operation, maintenance, and closure and post-closure care of the facility. For a facility where waste will remain after closure, I acknowledge that I have a responsibility to file with the county deed records an affidavit to the public advising that the land will be used for a solid waste facility prior to the time that the facility actually begins operating as a municipal solid waste landfill facility, and to file a final recording upon completion of disposal operations and closure of the landfill units in accordance with Title 30 Texas Administrative Code §330.19, Deed Recordation. I further acknowledge that I or the operator and the State of Texas shall have access to the property during the active life and post-closure care period, if required, after closure for the purpose of inspection and maintenance."

Kurt Fenstermacher

SAIC®

1.1.1 General

SAIC Energy, Environment and Infrastructure, LLC (SAIC) is pleased to submit this Major Permit Amendment (MPA) application on behalf of the City of El Paso (City) to the Texas Commission on Environmental Quality (TCEQ).

This MPA application is organized into four parts as per the requirements set forth in 30 TAC Chapter 330 Subchapter B. The following describes the contents of the four parts.

- **Part I.** This portion of the MPA application includes information from 30 TAC §281.5, 30 TAC §305.45 and 30 TAC §330.59 relating to the McCombs Landfill (Landfill) and the City, the facility's owner and operator.
- **Part II.** This section contains information regarding the existing conditions at the Landfill to fulfill the requirements of 30 TAC §330.61.
- **Part III.** Part III contains the design data and specifications, analytical reports, and engineering drawings required by 30 TAC §330.63.
- **Part IV.** Part IV includes the Site Operating Plan (SOP) which describes the daily operations at the Landfill as per 30 TAC 30 TAC §330.65.

1.1.2 Supplementary Technical Report

The City owns and operates the Type I municipal solid waste disposal facility which is managed under Municipal Solid Waste (MSW) permit 729B. The Landfill is located in El Paso County within the El Paso city limits and serves the waste needs of the City and the surrounding area.

In 2005, the City ceased regular solid waste disposal activities, and the majority of the City's MSW was diverted to the City's Clint Landfill as well as private facilities. During this period, the Landfill was primarily used for the disposal of storm debris and material generated from street cleanings. The City estimates that the Clint Landfill will undergo final closure activities in 2030, and wishes to return the Landfill to full activities to meet immediate and future solid waste disposal needs.

The vertical expansion will increase the height of the Landfill from the previous permitted elevation of 4,125 feet mean sea level (MSL) to 4,305 feet MSL. This corresponds to an increase in capacity of 46,148,275 cubic yards (CY) from a previously permitted volume of 22,348,549 CY to a new permitted volume of 68,817,242 CY.

As described in the site life projections provided in Appendix 3H, the McCombs Landfill is anticipated to receive 3,000 tons per year from 2011 through 2013 (storm debris) and 497,300 tons per year in 2014 increasing at a 2% growth rate throughout

the life of the Landfill. Also, it is assumed that in 2030, the Clint Landfill will reach capacity and the McCombs Landfill will receive all incoming waste (or 1,517,100 tons in 2030). Based on these assumptions, and a 0.60 tons per cubic yard airspace utilization factor, the site capacity is estimated to be consumed in 2059 (when utilizing either the prescriptive final cover or alternative final cover). The maximum rate of disposal is estimated to be approximately 2,694,000 tons per year (2059). The Landfill will be utilized following the Sector classifications in that Sector B will follow Sector A, Sector C will follow Sector B, etc.

Also included within this MPA is the disposal of C&D waste on top of the existing unlined landfill, which will act as a surcharge on the waste to enhance settlement prior to piggybacking over the waste with MSW. The C&D waste will be limited to 30-feet of fill, with the remainder of fill needed to reach the MSW base grades be obtained with uncontaminated soil. The C&D waste used for fill within the piggyback liner area will consist of (Class 3 like) inert wastes including (but not limited to) rock/stone, concrete, uncontaminated soil, masonry (brick, stucco and plaster), ceramic items, conduit and pipes, glass, inert plastics, molded fiberglass, and incidental amounts (no more than 5% per load) of metals (including aluminum). Any voids in all inert plastic materials accepted will be removed upon waste compaction. A complete list is provided in Section 2.2.1. It is estimated that based on a 60,000 tons per year disposal rate (2013), 2% growth, and 0.90 tons per cubic yard airspace utilization factor, that the C&D area will reach capacity in 2036.

As per 30 TAC §330.15, the Landfill will not accept hazardous wastes for disposal. These hazardous wastes include lead acid storage batteries, do-it-yourself motor vehicle oil, used oil filters, whole used or scrap tires, refrigerators, freezers, air conditioners, and other items containing chlorinated fluorocarbons (CFCs), bulk or non-containerized liquid waste, regulated hazardous waste as defined in 30 TAC §330.3, polychlorinated biphenyl (PCB) wastes, and radioactive materials. This list is further defined in Section 4.7.1.

The Landfill will accept MSW as defined by 30 TAC §330.3 and some special waste. Special wastes include Class II industrial wastes and municipal commercial waste such as treated medical waste, processed grease/grit trap waste, dead animals, slaughterhouse wastes, and petroleum-product and crude oil contaminated soil. The acceptance of special wastes is further defined in Appendix 4D. Special waste also includes RACM as described below.

The Landfill intends to dispose of regulated asbestos containing material (RACM) as defined in 40 Code of Federal Regulations Part 61 in accordance with 30 TAC §330.171(c)(3). This permit amendment will serve as the notification to the TCEQ of the intent to accept RACM. The procedures for accepting, disposing and recordkeeping are described in further detail in Section 4.9.22. Sector K will be utilized for the disposal of RACM.

This MPA also increases the property/facility area from 327.292 acres to 346.74 acres within Section 6, Block 80, Township 1, Texas and Pacific Railway Survey. An updated metes and bounds is provided in Appendix 1C. It should be noted that the increase is only for the property/facility boundary and the permitted waste footprint size is not increasing.

1.2.1 Facility Location and Description

The Landfill is an existing Type 1 MSW disposal facility owned and operated by the City. The Landfill is located at the northeast corner of the intersection of McCombs Road and Stan Roberts Road (FM 2529) in El Paso, Texas. The address of the Landfill is 13660 McCombs Road.

1.2.2 Access Routes

The Landfill is accessible through the entrance located on McCombs Road approximately 4.4 miles west of the intersection of McCombs Road with US 54 North. More specific transportation information can be found in Appendix 2C – Transportation Study. Greater detail regarding the location of the Landfill in relation to major thoroughfares can be found in Appendix 1A – General Location Maps.

1.2.3 Geographic Coordinates

The latitudinal and longitudinal geographic coordinates of the Landfill are:

- Latitude: N 32° 59’ 15”
- Longitude: W 106° 24’ 19”
- Elevation (above MSL): Approximately 4070’ near existing entrance.

1.3.1 General Location Maps

As per the requirements of 30 TAC §330.59(c)(1)-(2) and 30 TAC §305.45 the following maps are included as part of Appendix 1A – General Location Maps:

- General Highway Map for El Paso County;
- Detailed Highway Map for El Paso County; and
- General Topographic Map for the Landfill and Surrounding Area.

All maps updated in the application were completed with the latest information available at the time of development.

1.3.2 Land Owner Map and Land Owners List

To meet the requirements of 30 TAC §305.45(a) and 30 TAC §330.59(c)(3), a Land Owner Map and Land Owners List describing parcel ownership within one quarter mile of the Landfill are included in Appendix 1B – Land Ownership Map and Land Owners List.

1.4.1 Legal Description

To meet the requirements of 30 TAC §330.59(d)(1), a metes and bounds survey for the Landfill permit boundary is included as Appendix 1C – Legal Description.

1.4.2 Property Owner Affidavit

The property owner affidavit has been included in Page 9 of the Part 1 Form 0650 submitted as part of this MPA application.

Section 1.5
LEGAL AUTHORITY
30 TAC 330.59(e)

The Landfill is owned and operated by the City of El Paso. No other persons or entities have greater than 20 percent ownership in the Landfill. As per the requirements of 30 TAC §330.59(e), the legal authority of the City has been verified and a copy of the charter filed with the State of Texas is available upon request.

The following evidence of competency has been prepared on behalf of the City to meet the requirements of 30 TAC §330.59(f).

1.6.1 Solid Waste Sites

The City has owned/operated several municipal solid waste processing and disposal facilities within the State of Texas. The following is a list of MSW processing and disposal facilities owned/operated by the City.

Facility Name	Facility Type	Permit Number	County
McCombs Landfill	Type I MSW Landfill	729A	El Paso
Clint Landfill	Type I MSW Landfill	1482, 2284	El Paso
Delta Transfer Facility	MSW Transfer Station	728	El Paso
Doniphan HHW Site	HHW Collection and Processing Site	120017	El Paso
Escobar CCS	Citizens' Collection Station	120022	El Paso
Harrison CCS	Citizens' Collection Station	120024	El Paso
Hondo Pass CCS	Citizens' Collection Station	120018	El Paso

The City does not own, operate or have a financial interest in any solid waste sites outside of the State of Texas.

1.6.2 Management and Personnel

The management and personnel dedicated to the Landfill are described in Part IV – Site Operating Plan, Section 4.4, Table 4.4-1 (Personnel Types and Descriptions) of this Major Permit Amendment application. A copy of this table has been included in Appendix 1D – Landfill Personnel and Equipment.

1.6.3 Equipment Dedicated to McCombs Landfill

The equipment dedicated to the Landfill is described in Part IV – Site Operating Plan, Section 4.4, Table 4.4-2 (Landfill Facility Equipment List) of this Major Permit Amendment application. A copy of this table has been included in Appendix 1D – Landfill Personnel and Equipment.

Section 1.7
APPOINTMENTS
30 TAC §330.59(g)

The appointments for this Major Permit Amendment application have been prepared as per the requirements set forth in 30 TAC §330.59(g) and 30 TAC §305.44. Ellen A. Smyth, P.E., Director of Environmental Services for the City of El Paso will act as the designated signatory on behalf of the City. Documentation of SAIC's appointment as the project engineer is provided in Appendix 1E – Engineer's Appointment.

Section 1.8
APPLICATION FEES
30 TAC §330.59(h)(1-2)

As per the requirements set forth in TCEQ Part 1 Form 0650, a payment for the amount of $150 has been submitted by the City to the TCEQ Financial Administration division. A receipt of this payment has been included as part of Appendix 1F – Application Fee Documentation.

SAIC®

1.1.1 General

SAIC Energy, Environment and Infrastructure, LLC (SAIC) is pleased to submit this Major Permit Amendment (MPA) application on behalf of the City of El Paso (City) to the Texas Commission on Environmental Quality (TCEQ).

This MPA application is organized into four parts as per the requirements set forth in 30 TAC Chapter 330 Subchapter B. The following describes the contents of the four parts.

- **Part I.** This portion of the MPA application includes information from 30 TAC §281.5, 30 TAC §305.45 and 30 TAC §330.59 relating to the McCombs Landfill (Landfill) and the City, the facility's owner and operator.
- **Part II.** This section contains information regarding the existing conditions at the Landfill to fulfill the requirements of 30 TAC §330.61.
- **Part III.** Part III contains the design data and specifications, analytical reports, and engineering drawings required by 30 TAC §330.63.
- **Part IV.** Part IV includes the Site Operating Plan (SOP) which describes the daily operations at the Landfill as per 30 TAC 30 TAC §330.65.

1.1.2 Supplementary Technical Report

The City owns and operates the Type I municipal solid waste disposal facility which is managed under Municipal Solid Waste (MSW) permit 729B. The Landfill is located in El Paso County within the El Paso city limits and serves the waste needs of the City and the surrounding area.

In 2005, the City ceased regular solid waste disposal activities, and the majority of the City's MSW was diverted to the City's Clint Landfill as well as private facilities. During this period, the Landfill was primarily used for the disposal of storm debris and material generated from street cleanings. The City estimates that the Clint Landfill will undergo final closure activities in 2030, and wishes to return the Landfill to full activities to meet immediate and future solid waste disposal needs.

The vertical expansion will increase the height of the Landfill from the previous permitted elevation of 4,125 feet mean sea level (MSL) to 4,305 feet MSL. This corresponds to an increase in capacity of 46,148,275 cubic yards (CY) from a previously permitted volume of 22,348,549 CY to a new permitted volume of ***68,817,242*** ~~68,496,824~~ CY.

As described in the site life projections provided in Appendix 3H, the McCombs Landfill is anticipated to receive 3,000 tons per year from 2011 through 2013 (storm debris) and 497,300 tons per year in 2014 increasing at a 2% growth rate throughout

the life of the Landfill. Also, it is assumed that in 2030, the Clint Landfill will reach capacity and the McCombs Landfill will receive all incoming waste (or 1,517,100 tons in 2030). Based on these assumptions, and a 0.60 tons per cubic yard airspace utilization factor, the site capacity is estimated to be consumed in 2059 (when utilizing either the prescriptive final cover or alternative final cover). The maximum rate of disposal is estimated to be approximately 2,694,000 tons per year (2059). The Landfill will be utilized following the Sector classifications in that Sector B will follow Sector A, Sector C will follow Sector B, etc.

Also included within this ***MPA*** ~~major permit amendment~~ is the disposal of C&D waste on top of the existing unlined landfill, which will act as a surcharge on the waste to enhance settlement prior to piggybacking over the waste with MSW. ***The C&D waste will be limited to 30-feet of fill, with the remainder of fill needed to reach the MSW base grades be obtained with uncontaminated soil.*** The C&D waste ***used for fill within the piggyback liner area*** will consist of (Class 3 like) inert wastes including (but not limited to) rock***/stone***, ***concrete, uncontaminated soil, masonry (***brick***, stucco and plaster), ceramic items, conduit and pipes,*** glass, ~~dirt,~~ ***inert*** ~~certain~~ plastics, ~~rubber, and similar materials that are not readily decomposable~~ ***molded fiberglass, and incidental amounts (no more than 5% per load) of metals (including aluminum)***. ***Any voids in all inert plastic materials accepted will be removed upon waste compaction.*** A complete list is provided in Section 2.2.1. It is estimated that based on a 60,000 tons per year disposal rate (2013), 2% growth, and 0.90 tons per cubic yard airspace utilization factor, that the C&D area will reach capacity in ***2036*** ~~2041~~.

As per 30 TAC §330.15, the Landfill will not accept hazardous wastes for disposal. These hazardous wastes include lead acid storage batteries, do-it-yourself motor vehicle oil, used oil filters, whole used or scrap tires, refrigerators, freezers, air conditioners, and other items containing chlorinated fluorocarbons (CFCs), bulk or non-containerized liquid waste, regulated hazardous waste as defined in 30 TAC §330.3, polychlorinated biphenyl (PCB) wastes, and radioactive materials. This list is further defined in Section 4.7.1.

The Landfill will accept MSW as defined by 30 TAC §330.3 and some special waste. Special wastes include Class II industrial wastes and municipal commercial waste such as treated medical waste, processed grease/grit trap waste, dead animals, slaughterhouse wastes, and petroleum-product and crude oil contaminated soil. The acceptance of special wastes is further defined in Appendix 4D. Special waste also includes RACM as described below.

The Landfill intends to dispose of regulated asbestos containing material (RACM) as defined in 40 Code of Federal Regulations Part 61 in accordance with 30 TAC §330.171(c)(3). This permit amendment will serve as the notification to the TCEQ of the intent to accept RACM. The procedures for accepting, disposing and recordkeeping are described in further detail in Section 4.9.22. Sector K will be utilized for the disposal of RACM.

This MPA also increases the ***property*** ~~permitted~~/facility area from 327.292 acres to 346.74 acres within Section 6, Block 80, Township 1, Texas and Pacific Railway Survey. An updated metes and bounds is provided in Appendix 1C. ***It should be noted that the increase is only for the property/facility boundary and the permitted waste footprint size is not increasing.***

1.1.1 General

SAIC Energy, Environment and Infrastructure, LLC (SAIC) is pleased to submit this Major Permit Amendment (MPA) application on behalf of the City of El Paso (City) to the Texas Commission on Environmental Quality (TCEQ).

This MPA application is organized into four parts as per the requirements set forth in 30 TAC Chapter 330 Subchapter B. The following describes the contents of the four parts.

- **Part I.** This portion of the MPA application includes information from 30 TAC §281.5, 30 TAC §305.45 and 30 TAC §330.59 relating to the McCombs Landfill (Landfill) and the City, the facility's owner and operator.
- **Part II.** This section contains information regarding the existing conditions at the Landfill to fulfill the requirements of 30 TAC §330.61.
- **Part III.** Part III contains the design data and specifications, analytical reports, and engineering drawings required by 30 TAC §330.63.
- **Part IV.** Part IV includes the Site Operating Plan (SOP) which describes the daily operations at the Landfill as per 30 TAC 30 TAC §330.65.

1.1.2 Supplementary Technical Report

The City owns and operates the Type I municipal solid waste disposal facility which is ~~currently~~ managed under Municipal Solid Waste (MSW) permit ~~729A. Upon approval of this document, the facility will operate under permit~~ 729B. The Landfill is located in El Paso County within the El Paso city limits and serves the waste needs of the City and the surrounding area.

In 2005, the City ceased regular solid waste disposal activities, and the majority of the City's MSW was diverted to the City's Clint Landfill as well as private facilities. During this period, the Landfill was primarily used for the disposal of storm debris and material generated from street cleanings. The City estimates that the Clint Landfill will undergo final closure activities in 2030, and wishes to return the Landfill to full activities to meet immediate and future solid waste disposal needs.

The ~~proposed~~ vertical expansion will increase the height of the landfill from the ***previous*** ~~currently~~ permitted elevation of 4,125 feet mean sea level (MSL) to 4,305 feet MSL. This corresponds to an increase in capacity of 46,148,275 cubic yards (CY) from a previously permitted volume of 22,348,549 CY to a new permitted volume of 68,496,824 CY.

As described in the site life projections provided in Appendix 3H, the McCombs Landfill is anticipated to receive 3,000 tons per year from 2011 through 2013 (storm

debris) and 497,300 tons per year in 2014 increasing at a 2% growth rate throughout the life of the Landfill. Also, it is assumed that in 2030, the Clint Landfill will reach capacity and the McCombs Landfill will receive all incoming waste (or 1,517,100 tons in 2030). Based on these assumptions, and a 0.60 tons per cubic yard airspace utilization factor, the site capacity is estimated to be consumed in 2059 (when utilizing either the prescriptive final cover or alternative final cover). The maximum rate of disposal is estimated to be approximately 2,694,000 tons per year (2059). The Landfill will be utilized following the Sector classifications in that Sector B will follow Sector A, Sector C will follow Sector B, etc.

Also ***included*** ~~proposed~~ within this major permit amendment is the disposal of C&D waste on top of the existing unlined landfill, which will act as a surcharge on the waste to enhance settlement prior to piggybacking over the waste with MSW. The C&D waste will consist of ***(***Class 3 ***like)*** inert wastes including (but not limited to) rock, brick, glass, dirt, certain plastics, rubber, and similar materials that are not readily decomposable. ***A complete list is provided in Section 2.2.1.*** It is estimated that based on a 60,000 tons per year disposal rate (2013), 2% growth, and 0.90 tons per cubic yard airspace utilization factor, that the C&D area will reach capacity in 2041.

As per 30 TAC §330.15, the Landfill will not accept hazardous wastes for disposal. These hazardous wastes include lead acid storage batteries, do-it-yourself motor vehicle oil, used oil filters, whole used or scrap tires, refrigerators, freezers, air conditioners, and other items containing chlorinated fluorocarbons (CFCs), bulk or non-containerized liquid waste, regulated hazardous waste as defined in 30 TAC §330.3, polychlorinated biphenyl (PCB) wastes, and radioactive materials. This list is further defined in Section 4.7.1.

The Landfill will accept MSW as defined by 30 TAC §330.3 and some special waste. Special wastes include Class II industrial wastes and municipal commercial waste such as treated medical waste, processed grease/grit trap waste, dead animals, slaughterhouse wastes, and petroleum-product and crude oil contaminated soil. The acceptance of special wastes is further defined in Appendix 4D. Special waste also includes RACM as described below.

The Landfill intends to dispose of regulated asbestos containing material (RACM) as defined in 40 Code of Federal Regulations Part 61 in accordance with 30 TAC §330.171(c)(3). This permit amendment will serve as the notification to the TCEQ of the intent to accept RACM. The procedures for accepting, disposing and recordkeeping are described in further detail in Section 4.9.22. Sector K will be utilized for the disposal of RACM.

This MPA also increases the permitted/facility area from 327.292 acres to 346.74 acres within Section 6, Block 80, Township 1, Texas and Pacific Railway Survey. An updated metes and bounds is provided in Appendix 1C.

1.1.1 General

SAIC Energy, Environment and Infrastructure, LLC (SAIC) is pleased to submit this Major Permit Amendment (MPA) application on behalf of the City of El Paso (City) to the Texas Commission on Environmental Quality (TCEQ).

This MPA application is organized into four parts as per the requirements set forth in 30 TAC Chapter 330 Subchapter B. The following describes the contents of the four parts.

- **Part I.** This portion of the MPA application includes information from 30 TAC §281.5, 30 TAC §305.45 and 30 TAC §330.59 relating to the McCombs Landfill (Landfill) and the City, the facility's owner and operator.
- **Part II.** This section contains information regarding the existing conditions at the Landfill to fulfill the requirements of 30 TAC §330.61.
- **Part III.** Part III contains the design data and specifications, analytical reports, and engineering drawings required by 30 TAC §330.63.
- **Part IV.** Part IV includes the Site Operating Plan (SOP) which describes the daily operations at the Landfill as per 30 TAC 30 TAC §330.65.

1.1.2 Supplementary Technical Report

The City owns and operates the ***Type I municipal solid waste disposal facility*** ~~Landfill~~ which is ***currently*** managed under Municipal Solid Waste (MSW) permit 729A. ***Upon approval of this document, the facility will operate under permit 729B.*** The Landfill is located in El Paso County within the El Paso city limits and serves the waste needs of the City and the surrounding area.

In 2005, the City ***ceased regular solid waste disposal activities*** ~~placed the Landfill under inactive status with the TCEQ~~, and the majority of the City's MSW was diverted to the City's Clint Landfill as well as private facilities. During this period, the Landfill was primarily used for the disposal of storm debris and material generated from street cleanings. The City estimates that the Clint Landfill will undergo final closure activities in 2030, and wishes to return the Landfill to ***full activities*** ~~an active status~~ to meet immediate and future solid waste disposal needs.

The proposed vertical expansion will increase the height of the landfill from the currently permitted elevation of 4,125 feet mean sea level (MSL) to 4,305 feet MSL. This corresponds to an increase in capacity of 46,148,275 cubic yards (CY) from a previously permitted volume of 22,348,549 CY to a new permitted volume of 68,496,824 CY.

As described in the site life projections provided in Appendix 3H, the McCombs Landfill is anticipated to receive 3,000 tons per year from 2011 through 2013 (storm debris) and 497,300 tons per year in 2014 increasing at a 2% growth rate throughout the life of the Landfill. Also, it is assumed that in 2030, the Clint Landfill will reach capacity and the McCombs Landfill will receive all incoming waste (or 1,517,100 tons in 2030). Based on these assumptions, and a 0.60 tons per cubic yard airspace utilization factor, the site capacity is estimated to be consumed in 2059 (when utilizing either the prescriptive final cover or alternative final cover). The maximum rate of disposal is estimated to be approximately 2,694,000 tons per year (2059). The Landfill will be utilized following the Sector classifications in that Sector B will follow Sector A, Sector C will follow Sector B, etc.

Also proposed within this major permit amendment is the disposal of C&D waste on top of the existing unlined landfill, which will act as a surcharge on the waste to enhance settlement prior to piggybacking over the waste with MSW. The C&D waste will consist of Class 3 inert wastes including (but not limited to) rock, brick, glass, dirt, certain plastics, rubber, and similar materials that are not readily decomposable. It is estimated that based on a 60,000 tons per year disposal rate (2013), 2% growth, and 0.90 tons per cubic yard airspace utilization factor, that the C&D area will reach capacity in 2041.

As per 30 TAC §330.15, the Landfill will not accept hazardous wastes for disposal. These hazardous wastes include lead acid storage batteries, do-it-yourself motor vehicle oil, used oil filters, whole used or scrap tires, refrigerators, freezers, air conditioners, and other items containing chlorinated fluorocarbons (CFCs), bulk or non-containerized liquid waste, regulated hazardous waste as defined in 30 TAC §330.3, polychlorinated biphenyl (PCB) wastes, and radioactive materials. ***This list is further defined in Section 4.7.1.***

The Landfill will accept MSW as defined by 30 TAC §330.3 and some special waste. Special wastes include Class II industrial wastes and municipal commercial waste such as treated medical waste, processed grease/grit trap waste, dead animals, slaughterhouse wastes, and petroleum-product and crude oil contaminated soil. The acceptance of special wastes is further defined in Appendix 4D. Special waste also includes RACM as described below.

The Landfill intends to dispose of regulated asbestos containing material (RACM) as defined in 40 Code of Federal Regulations Part 61 in accordance with 30 TAC §330.171(c)(3). This permit amendment will serve as the notification to the TCEQ of the intent to accept RACM. The procedures for accepting, disposing and recordkeeping are described in further detail in Section 4.9.22. ***Sector K will be utilized for the disposal of RACM.***

1.3.1 General Location Maps

As per the requirements of 30 TAC §330.59(c)(1)-(2) and 30 TAC §305.45 the following maps are included as part of Appendix 1A – General Location Maps:

- General Highway Map for El Paso County;
- Detailed Highway Map for El Paso County; and
- General Topographic Map for the Landfill and Surrounding Area.

All maps updated in the application were completed with the latest information available at the time of development.

1.3.2 Land Owner Map and Land Owners List

To meet the requirements of 30 TAC §305.45(a) and 30 TAC §330.59(c)(3), a Land Owner Map and Land Owners List describing parcel ownership within one quarter mile of the Landfill are included in Appendix 1B – Land Ownership Map and Land Owners List.

Appendix 1C
Legal Description

SAIC®

Prepared for: City of El Paso
(McCombs Landfill)
October 16, 2012

METES AND BOUNDS

Description of a parcel of land being a portion of Section 6, Block 80, Township 1, Texas and Pacific Railway Company Surveys, City of El Paso, El Paso County, Texas and being more particularly described by metes and bounds as follows:

Commencing for reference at a point marking the common corner of Sections 6 and 7, Block 80 and Sections 1 and 12, Block 81, Township 1, Texas and Pacific Railway Company Surveys from which a point marking the common northerly corner of Section 1, Block 81 and Section 6, Block 80, bears North 02°06'50" East a distance of 5357.59 Feet; Thence along the line between Section 1, Block 81 and Section 6, Block 80, North 02°06'50" East a distance of 620.00 feet to The "TRUE POINT OF BEGINNING"

Thence along said common line, North 02°06'50" East a distance of a distance of 800.00 feet to a point;

Thence leaving said line South 86°43'10" East a distance of 250.00 feet to a point;

Thence, North 02°06'50" East a distance of 406.85 feet to a point;

Thence North 86°43'10" West a distance of 250.00 feet to a point on the common line between Section 1, Block 81, Township 1 and Section 6, Block 80,.Township 1, Texas and Pacific Railway Company Surveys;

Thence along said line, North 02°06'50" East a distance of 3133.27 feet to a point;

Thence leaving said line, South 86°58'10" East a distance of 3312.66 feet to a point;

Thence, South 02°17'50" West a distance of 4299.15 feet to a point;

Thence, North 86°43'13" West a distance of 1028.44 feet to a point;

Thence, South 00°14'23" West a distance of 449.69 feet to a point;

Thence, North 86°52'09" West a distance of 2258.08 feet to a point;

Thence, North 02°33'30" East a distance of 399.85 feet to a point;

Thence, North 86°43'10" West a distance of 30.33 feet to the TRUE POINT OF BEGINNING and containing 14,256,826.83 Square Feet or 327.29 Acres of land more or less.

Note: Not a ground survey, bearings based on survey of 19.442 Acre portion of Section 6, Block 80, Township 1, Texas and Pacific Railway Company Surveys prepared by Robert Seipel Associates, Inc., dated May 4, 2011.

A drawing of even date accompanies this description.

Landfill Personnel and Equipment

SAIC®

Table 4.4-1
Personnel Types and Descriptions

Position	Number of Employees	Minimum Qualifications	Position Function
Director of Environmental Services	1	Must hold and maintain Landfill Operator license Class A. Minimum 1 year landfill operation.	Serves in landfill manager capacity when landfill manager is unavailable.
Solid Waste Operations Manager	1	Must hold and maintain Landfill Operator license Class A. Minimum 1 year landfill operation.	Manages all landfill activities.
Solid Waste Division Supervisor	1	Must hold and maintain Landfill Operator license Class B. Minimum 1 year landfill operation experience. Training by the Solid Waste Operations Manager in the SOP requirements.	Responsible for managing work face and daily fill and cover placement operations, landfill equipment maintenance and repair, and personnel safety during waste and cover construction.
Equipment Operator	4 (0 tpd – 1500 tpd) 5 (1501 tpd – 2500 tpd) 6 (2501 tpd – 3500 tpd)	6 months minimum experience in equipment operation or on the job training by experienced equipment operators and training by Landfill Manager in SOP requirements for daily cover and unauthorized waste.	Grading and excavating, necessary equipment maintenance, waste leveling and compaction, application of daily cover, and general site road maintenance. Operators are also responsible for keeping the working face in the smallest area practical and screening for unauthorized waste.
Senior Cashier/Accounting Payroll Specialist	1	Training by Solid Waste Operations Manager in the SOP rules and waste screening training course (e.g., I.I.E.D.)	Providing oversight for and filling in for the landfill cashiers as needed.
Cashiers	2 or more	Training by Solid Waste Operations Manager in the SOP rules, and waste screening training course (e.g., I.I.E.D.)	Levies fees on landfill customers. Operates the scale, keeps appropriate records, controls site access screens for unauthorized waste, and provides general customer direction and information.

Table 4.4-1
Personnel Types and Descriptions

Position	Number of Employees	Minimum Qualifications	Position Function
Maintenance Personnel	2 (0 tpd – 1500 tpd) 3 (1501 tpd – 3500 tpd)	Internal safety training and personal protective equipment training	General facility maintenance. Picks up windblown litter as directed. Directs traffic at disposal area.

Table 4.4-2
Landfill Facility Equipment List

Equipment Type	Number (Minimum)	Typical Size	Function
Dozers (tractor)	1 (0 tpd–1500 tpd) 2 (1501 tpd–3500 tpd)	240 HP or greater	Waste and soil spreading and compaction
Scraper	1 or more (0 tpd–1500 tpd) 2 or more (1501 tpd–3500 tpd)	Greater than 20 cubic yards (cy)	Transportation of daily cover, fire fighting support
Compactor	1 or more (0 tpd–1500 tpd) 2 or more (1501 tpd–3500 tpd	Greater than 80,000 lbs	Waste spreading and compaction
Water Truck	1	At least 5,000 gallons	Dust control, fire fighting support
Diesel Fuel Tank	1	10,500 gallons	Vehicle fueling
Street Sweeper or sweeper attachment brush for loader	1	5 foot broom	Cleaning of paved on-site roads
Portable Litter Screens	4 or more	10 feet by 10 feet	Active face litter control
Road Grader or Maintainer	1	Size varies	Grading of access roads, soil spreading
Bucket Loader	1	25 cubic yards	Earth moving
Submersible Leachate Pumps	1 per sump		Transfer of leachate from sumps
Electronic liquid level indicators	1 per sump		Monitor leachate level in sumps

SERVICE SOLUTIONS SUCCESS

November 21, 2011

Mark R. Vickery, P.G.
Executive Director
Texas Commission on Environmental Quality
P.O. Box 13087
Austin, TX 78711-3087

Subject: **Notice of Engineer's Appointment**

Dear Mr. Vickery:

This letter is provided to inform you that the City of El Paso has appointed SAIC as the consulting and design engineers responsible for the Major Permit Amendment for the McCombs Landfill (MSW Permit No. 729A).

I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

Sincerely,

Ellen A. Smyth, P.E.

Director of Environmental Services
City of El Paso

SWORN AND SUBSCRIBED BEFORE ME on this 21st day of November, 2011, which witness my hand and seal of office.

2.1.1 Existing Conditions Overview

The Landfill is located on approximately 347 acres in rural El Paso County, Texas and serves the greater City of El Paso area. The Landfill was originally permitted in 1976, with subsequent permitting to 327 acres in 1984. This MPA includes the addition of 19.4 acres to include the site entrance facilities within the permitted boundary. The development of the Landfill generally followed the progression of a sand and gravel quarry in that location.

The following summarizes the Landfill's permitting timeline from the TCEQ and its predecessors: Texas Natural Resource Conservation Commission (TNRCC) and the Texas Department of Health (TDH).

- **1976:** Original MSW Permit 729 issued by TDH.
- **1984:** Permit amendment completed to expand acreage from 25 acres to 327 acres. MSW Permit 729A was issued by TDH.
- **1995:** Alternative liner design approved.
- **2002:** Site Development Plan (SDP) permit modification completed.
- **2004:** Closure and post-closure care cost estimates updated.
- **2006:** Site Operating Plan (SOP) updated to comply with current regulations.
- **2009:** Landfill Gas Collection and Control System (GCCS) permit modification completed.
- **2009:** Groundwater Sampling and Analysis Plan permit modification completed.

The Landfill serves the MSW disposal needs of the City of El Paso area. This represents a metropolitan population of 620,456, according to 2009 projections from the United States Census Bureau. The Landfill also accepts waste from neighboring communities in El Paso County, Texas and from Doña Ana County, New Mexico.

As discussed in Section 1.1.2 – Supplementary Technical Report, in 2005, the City ceased regular solid waste disposal activities, and the majority of the City's MSW was diverted to the City's Clint Landfill as well as private facilities. During this period, the Landfill was primarily used for the disposal of storm debris and material generated from street cleanings. The City estimates that the Clint Landfill will undergo final closure activities in 2030, and wishes to return the Landfill to full activities to meet immediate and future solid waste disposal needs. To account for the expected increase in waste, the City developed a vertical expansion of the existing Landfill from 4,125 feet MSL to 4,305 feet MSL to meet their solid waste disposal needs.

2.1.2 Permits and Authorizations

The following Table 2.1-1 summarizes the existing permits and authorizations for the Landfill.

Table 2.1-1
Current McCombs Landfill Permits and Authorizations

Permit Type	Permit Number
TCEQ Texas Pollutant Discharge Elimination System (TPDES) Stormwater Permit	TXR05L795
TCEQ Air New Source Permit	81742
TCEQ Subchapter U: Standard Air Permit	1749
TCEQ Wastewater General Permit	2E0000049

2.1.3 Site-Specific Conditions

In accordance with 30 TAC §330.61(a), a detailed discussion of the site-specific special conditions at the Landfill is included throughout Part II of this MPA application. Items discussed in Section 2.4 through Section 2.10 include the impact on the surrounding area, transportation, general geology and soils, groundwater and surface water, abandoned oil and water wells, floodplains and wetlands, and endangered or threatened species.

There are no existing site-specific conditions that require special design considerations or possible mitigation of conditions.

2.2.1 Sources and Characteristics of Waste

The majority of the waste that will be accepted by the Landfill will be classified as MSW (defined in 30 TAC §330.3(88)). MSW accepted in the lined portion of the Landfill will be typically generated from household, residential, commercial, institutional, municipal, manufacturing, industrial, recreational, and construction-demolition sources.

The Landfill also intends to accept construction and demolition (C&D) waste on top of the existing unlined landfill that will consist of (Class 3 like) inert wastes. More specifically, C&D waste will consist of (but is not limited to):

- Rock/stone;
- Concrete;
- Uncontaminated soil;
- Masonry (brick, stucco and plaster);
- Aluminum[1];
- Ceramic items;
- Conduit and pipes (free of asbestos);
- Glass;
- Inert Plastics (any voids in materials accepted will be removed upon waste compaction);
- Molded fiberglass; and
- Metal.[1];

The Landfill will also accept several types of special wastes as described in the Special Waste Acceptance Plan included in Part IV – Site Operating Plan. Acceptable special wastes include Class II industrial waste and municipal commercial waste such as treated medical waste, processed grease/grit trap waste, dead animals, slaughterhouse wastes, and petroleum-product or crude oil contaminated soil. The Landfill also intends to accept regulated asbestos containing material (RACM) as described in Section 4.9.22.

As per 30 TAC §330.15, the Landfill will not accept hazardous wastes for disposal. These hazardous wastes include lead acid storage batteries, do-it-yourself motor vehicle oil, used oil filters, whole used or scrap tires, refrigerators, freezers, air

[1] For C&D material to be used within the area of the piggyback liner profile (referred throughout as Scenario 3), metals (including aluminum) shall be limited to incidental amounts (no more than 5% per load).

conditioners, and other items containing chlorinated fluorocarbons (CFCs), bulk or non-containerized liquid waste, regulated hazardous waste as defined in 30 TAC §330.3, polychlorinated biphenyl (PCB) wastes, and radioactive materials.

Specific information regarding the movement of these wastes through the Landfill is discussed in Section 3.2.2.

2.2.2 Projected Waste Acceptance Rates

The Landfill will serve the communities, businesses and institutions in and around the City of El Paso, Texas. The facility ceased regular solid waste disposal activities in 2005 and has only received minimal waste from storm events and street cleanings in the past 5 years. This amounted to approximately 3,785 tons in FY 2010.

The Landfill will continue accepting only minimal waste from 2011 through 2013. Based on research of the current waste stream and conversations with City staff, SAIC estimates that the Landfill may receive approximately 497,309 tons per year (TPY) starting in 2014. In general, this acceptance rate will likely increase over the life of the Landfill due to an expected increase in the population served, but may vary due to conditions in the solid waste market.

The estimated maximum annual waste acceptance rate for the Landfill projected for five years is summarized in Table 2.2-1.

Table 2.2-1
Estimated Maximum Annual Waste Acceptance
(FY 2011 to FY 2015)

FY	Estimated Maximum Waste Acceptance Rate (Tons)
2011	3,000
2012	3,000
2013	3,000
2014	497,309
2015	507,255

Once the vertical expansion is approved, the Landfill will have a remaining disposal capacity of approximately 62,853,182 cubic yards (CY) of soil and waste. This will allow the Landfill to have adequate capacity through approximately 2059, assuming that the City's Clint Landfill undergoes closure in the year 2030 and all of the City's MSW disposal needs are met by the McCombs Landfill.

2.2.3 Population Equivalent

According to 30 TAC §330.3, the population equivalent is defined as the hypothetical population that would generate an amount of solid waste equivalent to that actually being managed based on a generation rate of five pounds per capita per day and applied to situations involving solid waste not necessarily generated by individuals. It is assumed, for the purpose of this section, that the average volume per ton of waste

entering a municipal solid waste disposal facility is three cubic yards. The projected population equivalent for the Landfill is calculated in Table 2.2-2.

Table 2.2-2
Projected Population Equivalent for McCombs Landfill

	2012	2020	2030	2040
Waste Accepted (ton/yr)	3,000	560,050	1,517,107	1,849,345
Waste Accepted (ton/day)[1]	8.219	1,534	4,156	5,067
Waste Accepted (lb/day)[2]	16,438	3,068,767	8,312,915	10,133,397
Population Equivalent[3]	3,288	613,753	1,662,583	2,026,679

1. Assumes waste generation 365 days per year.
2. Assumes 2,000 lb per ton.
3. Assumes per capita generation rate of 5 pounds as per 30 TAC §330.3.

2.3.1 General Location Maps

As required by 30 TAC §330.61(c), general location maps have been provided in Appendix 2A - Maps. These maps have been provided in addition to those required by 30 TAC §330.59(c) relating to contents in Part I of the application and present information on the general character of the surrounding land. The required information per 30 TAC §330.61(c) and the information location within the report is summarized below:

> *"1) the prevailing wind direction with a wind rose;"*

The wind rose provided from TCEQ is shown on Drawing P1-3 (Appendix 1A). The wind rose period of record is from 1984 to 1992. The wind rose frequency of occurrence of winds is plotted in the sixteen points of the compass, with a maximum of six wind speed classes for each direction.

> *"2) all known water wells within 500 feet of the proposed permit boundary with the state well numbering system designation for Water Development Board "located wells";"*

Known water wells within 500-feet are provided in Section 2.4.2.

> *"3) all structures and inhabitable buildings within 500 feet of the proposed facility;"*

Three buildings were identified within 500-feet of the facility boundary. These buildings include the CEMEX Quarry office and scale house and site trailers.

> *"4) schools, licensed day-care facilities, churches, hospitals, cemeteries, ponds, lakes, and residential, commercial, and recreational areas within one mile of the facility;"*

Drawing P2-3 provides a land use map for the Landfill within one mile of the facility. Residential, commercial, and recreational areas are shown within this boundary. Table 2.4B-1 also provides a breakdown of the areas within the one mile radius by land use. Additionally, as stated, there are no schools, licensed day-care facilities, churches, hospitals, cemeteries or lakes within one mile of the Landfill. One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.

> *"5) the location and surface type of all roads within one mile of the facility that will normally be used by the owner or operator for entering or leaving the facility;"*

The three main roads to be used by the facility (McCombs St, Stan Roberts Sr. Ave, and State Line Drive; locations shown on P2-1) are two-lane asphalt paved roads.

" 6) latitudes and longitudes;"

The latitudes and longitudes of the facility are provided on Drawings P2-1 and P2-2.

"7) area streams;"

There were not any streams identified within a 1-mile radius of the facility.

"8) airports within six miles of the facility;"

Airport locations within the vicinity of the facility are provided in Drawing P2-4.

"9) the property boundary of the facility;"

The property boundary is shown on several drawings included in Appendix 2A.

"10) drainage, pipeline, and utility easements within or adjacent to the facility;"

Facility easements are provided on Drawing P2-7 and are also discussed in Section 4.9.6.

"11) facility access control features; and"

Access to the Landfill is restricted by an existing barbed wire fence located along the perimeter of the facility as well as a locking gate at the facility entrance as depicted on Drawing P2-7.0 and as described in Section 3.2.1.

"12) archaeological sites, historical sites, and sites with exceptional aesthetic qualities adjacent to the facility."

As stated in Appendix 2B – Land Use Analysis, Page 2B-3, no archaeologically significant sites, historical sites, or locations of exceptional aesthetic quality were located within one-mile of the Landfill.

2.3.2 Facility Layout Maps

Facility layout maps have been provided in Appendix 2A - Maps, as per the requirements set forth in 30 TAC §330.61(d). These maps have been prepared to show the outline of the landfill units, general locations of the main interior facility roadways, locations of monitoring wells, locations of buildings, fencing, natural windbreaks, site entrance roads, and a delineation of the landfill sectors including sequencing of excavation and filling activities.

Existing earthen berms along the western and northern boundaries of the Landfill provide a method of visual screening for the facility.

2.3.3 General Topographic Map

Consistent with the regulations set forth in 30 TAC §330.61(e), United States Geologic Survey (USGS) 7 ½ minute quadrangle sheets for El Paso County have been provided to show the topography of the site. This general topographic map is

provided in Appendix 2A – Maps and is shown at a scale of one inch equals 2,000 feet.

2.3.4 Aerial Photograph

A series of aerial photographs have been provided in Appendix 2A – Maps as Drawings P2-5 and P2-6. Drawing P2-5 is from an aerial survey completed in February 2011 by Cooper Aerial Surveys Company. This aerial survey was utilized to determine the existing topography at the site. Drawing P2-6 has been provided from Google Earth to meet the requirements set forth in 30 TAC §330.61(f). This aerial photograph has a scale of approximately 1,050 feet equals one inch and shows the area within a one mile radius of the Landfill. This Google Earth image is based on source data from the Texas Ortho Imagery Program and the United States Department of Agriculture (USDA) from April 1, 2008 to June 13, 2010.

2.3.5 Land Use Map

As per the requirements in 30 TAC §330.61(g), a land use map has been provided in Appendix 2A – Maps. This map has been prepared using county-provided parcel data from El Paso County, Texas and Doña Ana County, New Mexico to depict land uses within one mile of the Landfill. A detailed written examination of this parcel data can be found in Appendix 2B – Land Use Analysis.

2.4.1 Impact on Surrounding Area

As per the requirements set forth in 30 TAC §330.61(h), an evaluation of the impact on the surrounding area was completed for the Landfill. A detailed land-use analysis is included as Appendix 2B – Land Use Analysis. This analysis includes information on zoning for the area within two miles of the property, the character of the surrounding land within one mile of the property, growth trends within five miles of the property, and the proximity of residences and other places of interest within one mile of the facility.

2.4.2 Wells Within 500 Feet of Landfill

Consistent with 30 TAC §330.61(c)(2), Drawing P2-23 - Land Use Map of Appendix 2B includes all known water wells within 500 feet of the Landfill. The location, identification and use of each of the water wells is summarized below in Table 2.4-1. As can be seen in this table, four wells are located within the specified radius, none of which are used for domestic supply.

Table 2.4-1
Known Water Wells within 500 Feet of Landfill

Well Number[1]	Well Use	Latitude	Longitude
4905309	Unused	32.00083	-106.410
4905314	Industrial Use	31.99028	-106.408
4905315	Industrial Use	31.99055	-106.408
4905325	Not Classified	31.99972	-106.409

1. Well number is designated by the Texas Water Development Board state numbering system.

To comply with the regulations in 30 TAC §330.61(h)(5), a search of the Texas Railroad Commission (TRRC) oil and gas well database was conducted in February 2011. This search did not identify any oil and gas wells within the property boundary or within 500 feet of the Landfill.

2.5.1 Overview

Consistent with the requirements set forth in 30 TAC §330.61(i), a Traffic Impact Analysis (TIA) was conducted by the City's Department of Transportation for the area immediately surrounding the Landfill. This TIA is included as Appendix 2C – Transportation Study and provides data on:

- The availability and adequacy of access roads for the site;
- Volume of vehicular traffic on access roads within one mile of the facility, both existing and expected, during the life of the facility; and
- The expected traffic volume to be generated by the facility on the access roads within one mile of the facility.

Documentation of coordination between the City and Edgar E. Fino from the Texas Department of Transportation (TxDOT) concerning the future roadway improvements and traffic and location restrictions is provided in Appendix 2C – Transportation Report.

2.5.2 Airport Safety

Pursuant to 30 TAC §330.61(i)(5), an evaluation of the facility was completed in accordance with 30 TAC §330.545(a). The identified airports within the general vicinity of the Landfill are provided in Appendix 2A – Maps. The Biggs Army Airfield was identified as being located approximately 9 miles from the Landfill and the El Paso International Airport was identified as being located approximately 11 miles from the Landfill. Additionally, correspondence was submitted to the Federal Aviation Administration to ensure that the Landfill is not:

1. Located within 10,000 feet of any airport runway end used by turbojet aircraft;
2. Within 5,000 feet of any airport runway end used by only piston-type aircraft;
3. Within a six mile radius of any small general service airport runway end used by turbojet or piston-type aircraft; or
4. Within a five mile radius of any large general public commercial airport runway end used by turbojet or piston-type aircraft.

Documentation of this correspondence is also provided in Appendix 2C.

Consistent with §330.61(j)(1)-(4), a general discussion of the geology and soils of the site has been prepared. Detailed discussion of the geology of the site can be found in Section 3.5 of this application. This statement was prepared based on documents submitted for the McCombs Landfill in previous permit modifications with referenced documents provided in the appendices of this major permit amendment.

2.6.1 Topography

The original topography of the site was likely hilly. Subsequent quarrying and landfilling operations have significantly modified the natural conditions of the site. The present topography is dominated by large depressions; remnants of the quarrying operations that may range up to 30 feet deep. The landfill areas are currently built-up to elevations over 40 feet above land surface.

2.6.2 General Geology[1]

The McCombs Landfill is located within the Rio Grande Rift portion of the Mexican Highlands section of the Basin and Range Physiographic Province (Fnneman, 1931 and Thornbury, 1965). The Mexican Highlands Section is an area of variable geologic structure characterized by high desert valleys and mountain ranges and is subdivided into the Bolson and Rio Grande subsections (Hawley, 1975). The Bolson Subsections cover a large area of southwestern New Mexico, portions of Texas, Chihuahua, Mexico and Arizona. This region is characterized by broad intermontane basins with internal drainage, called bolsons, that are bounded by fault-block mountain ranges.

The mountain ranges on the eastern side of the Bolson subsection trend in a general north-to-northwest direction and typically flank sizeable basins, including the Hueco Bolson in which the site is located (Thornbury, 1965). The Rio Grande Valley in incised into thick deposits of basin fill at the southern end of the Hueco Bolson typically ranging in age from Pliocene to Holocene. A broad alluvial plain with gently sloping terraces characterize the valley of the Rio Grande River.

Tectonic basin formation began in the region in the early Miocene. With basin development, erosion and subsequent deposition of the Santa Fe Group sediments occurred (Gile, et al, 1981; Strain, 1966). Renewed faulting in Late Miocene and Pliocene time, coupled with uplift, produced a series of en echelon grabens, such as the Mesilla and Hueco Bolson that characterize this section of the Rio Grande Rift Valley. These bolsons received several thousands of feet of sediment during the Late Cenozoic (Strain, 1966). The ancestral Rio Grande River flowed into the closed

[1] Site Characterization and Monitoring Plan, McCombs Municipal Landfill, El Paso, Texas, SHB-AGRA, October 1993 (Appendix 3K, Attachment 1)

basins in the area during the Pliestocene depositing thick sequences of sediment and forming an ephemeral lake (Strain, 1969).

The Hueco Bolson deposits were divided into two rock stratigraphic units, the Fort Hancock Formation and the Camp Rice Formation (Strain, 1969). The older Fort Hancock Formation is a massive unit composed of poorly consolidated clays, silt and fine-grained sands. In the early Pleistocene time, adjacent basins aggraded to levels sufficient to coalesce with the Hueco Bolson. Periods of high precipitation resulted in the formation of a large ephemeral lake system, Lake Cabeza de Vaca (Strain, 1966). Deposits of fine-grained sediments in the Hueco Bolson continued until an outlet to the southeast formed in the early Pliestocene. This outlet breached Lake Cabeza de Vaca and changed the depositional environment from predominantly lacustrine to fluvial (Strain, 1980).

The Camp Rice Formation unconformably overlies the Fort Hancock Formation and is primarily composed of gravel, sand, silt and occasional discontinuous lenses of volcanic ash. The Camp Rice Formation is composed of two basic subdivisions, a fluvial and a piedmont facies (Gile, et al, 1981). The fluvial facies is chiefly sand to pebbly river-channel deposits with subordinate fine-grained overbank units. This facies thickens toward the bolson axes and commonly wedges out against the piedmont facies. The permitted landfill area is probably underlain by fluvial deposits of the Camp Rice Formation.

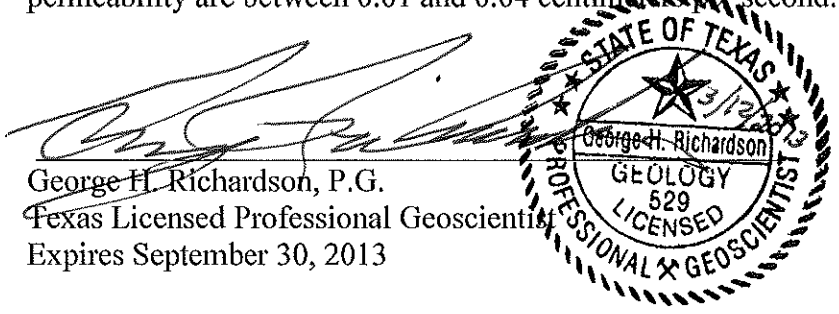
2.6.3 General Soils

The McCombs Landfill is located on deposits of the Hueco Bolson, probably Camp Rice Formation. These deposits primarily consist of clay, sand, and gravel, with some caliche. The landfill site is underlain by Tertiary and Quaternary basin (bolson) deposits, overlain by areas of gravel and caliche rimrock. Recent Quaternary alluvial deposits are also present in the landfill vicinity in topographically low areas.

Boring logs for wells drilled on site to depths greater than 500 feet generally indicate deposits of:

- 0 – 50 feet Sand, and sand and gravel;
- 50-250 feet Sand, with some clay;
- 250-470 feet Sand and fine gravel mix; and
- 470-560 feet Sandy clay.

In general, the relatively clean sands are non-plastic, while sandy clay ranges from low to high plasticity. Permeability tests were not considered necessary based on the soil types encountered during the site characterization. Estimated coefficients of permeability are between 0.01 and 0.04 centimeters per second.



George H. Richardson, P.G.
Texas Licensed Professional Geoscientist
Expires September 30, 2013

2.6.4 Fault Areas[2]

The fault area restriction states that no new landfill units or lateral expansions can be placed within 200 feet of a fault that has experienced Holocene displacement. This restriction provides for minimal setbacks from actual fault traces since faults can result in damage to the landfill's integrity through:

- Movement along the fault causing displacement;
- Seismic activity associated with faulting resulting in seismic shaking of facility structures; and
- Seismic shaking resulting in slope failures.

The original permit states that "...an Eastern Boundary Fault Zone exists between the Franklin Mountains and the Hueco Bolson deposits" and "...assuming continuous movement this (movement of the fault) would equate to approximately 0.005 inches per year" (DRA, 1984).

Since several Quaternary faults have been identified within and at the margins of the Hueco Bolson, SHB reviewed recent published geologic mapping and literature to evaluate the proximity and age of known faults in the vicinity of the McCombs Landfill.

Numerous fault scarps of Quaternary age are preset in the Hueco Bolson near the Landfill. One inferred scarp apparently traverses the northeastern quadrant of the Landfill permit area (SHB, 1993). This fault was not identified on the geologic map prepared by Harbour (1972). Insufficient information is available to confirm or refute the presence of the fault. This fault is more than 200 feet from any existing or proposed Landfill units. Other north-south trending scarps are also apparent in the area.

The age of faulting in Hueco Bolson has been dated as less than 0.5 million years (m.y.), based on offset in the Camp Rice Formation and in soils formed on the Camp Rice formation (Seager 1980). A report by Collins and Raney (1991), indicates that those faults near the site displace deposits of middle Pliestocene age (approximately 200,000 to 900,000 years old). Evidence of displacement of younger deposits have not been documented either because younger sediments do not exist along the fault traces or have been covered by windblown sand. Collins and Raney (1991) point out that movement on the basin bounding the East Franklin Mountains located a few miles to the west of the landfill may be as young as Holocene. Other basin bounding faults and some of the intragraben faults (such as those near the Landfill) most recently experienced rupture during the middle to late Pliestocene. More precise dating of the faults has not been performed, however, it is apparent that the faults have recurrence intervals of more than 10,000 years; otherwise the fault traces would be more clearly defined.

[2] Evaluation of Location Restrictions, McCombs Landfill, El Paso, Texas, SHB-AGRA June 1994 (Appendix 3K, Attachment 4)

2.6.5 Seismic Impact Zones[2]

The seismic impact zone restrictions (30 TAC §330.557) states that "New municipal solid waste landfill (MSWLF) units and lateral expansions shall not located in seismic impact zones, unless the owner or operator demonstrates to the Director that all containment structures, including liners, leachate collection systems, and surface water control systems, are designed to resist the maximum horizontal acceleration in lithified earth materials for the site."

Under this regulation, a seismic risk zone is considered to be an area that has a 10 percent or more probability that the maximum horizontal acceleration in lithified material, expressed as a percentage of the earth's gravitational pull (g), will not exceed 0.10g in 250 years.

This regulation pertains to new MSWLF units and lateral expansions. This permit modification is a vertical expansion of the existing permitted Landfill and no new horizontal area will be opened under this permit modification. Based on the work completed by SHB-AGRA (1994) a review of USGS Miscellaneous Field Study Map MF-2121, "Probabilistic Earthquake Acceleration and Velocity Maps for the United States and Puerto Rico", (Algermissen, et. al, 1991) was conducted. El Paso County (and the Landfill) fall outside of any designated seismic impact zone.

The map on Figure 2-1 is from the USGS website:

http://earthquake.usgs.gov/hazards/apps/map/

Based on 2008 revised data, this map demonstrates the facility is located within a seismic impact zone and exceeds the 30 TAC §330.557 standard of 10 percent or more probability. The seismic impact zone restrictions only apply to new MSWLF units and lateral expansions. The permit modification for the Landfill is for a vertical expansion and no previously-undisturbed earth will be added to the Landfill boundary.

The acreage within the proposed facility boundary was increased for this permit amendment from 327.29 to 346.74 acres at the request of the TCEQ to reflect the existing Landfill buildings and retention ponds that were submitted and approved by the TCEQ under Permit Amendment 729A. These features included existing buildings associated with the landfill operations on property previously leased and now owned by the City of El Paso. Retention ponds within this area were designed by Moreno Cardenas, Inc. to handle runoff from existing buildings and infrastructure (Permit Amendment 729-A, December 2010) in accordance with the applicable codes in place at that time.

2.6.6 Unstable Areas

Consistent with 330.61(j)(4) and 330.559, unstable areas documentation was prepared and part of the application to demonstrate that the Landfill meets the location restriction for unstable area.

TCEQ regulations require the owner or operators of new MSWLF units, existing MSWLF units and lateral expansions located in an unstable area shall demonstrate that engineering measures have been incorporated into the MSWLF unit's design to

ensure that the integrity of the structural components of the MSWLF unit will not be disrupted.

An unstable area is defined by TCEQ as a location that is susceptible to natural or human-induced events or forces capable of impairing the integrity of some or all of the landfill's structural components responsible for preventing releases from a landfill. An unstable area can exhibit poor foundation conditions, area susceptible to mass movement, and karst terrains.

2.6.6.1 Unstable Slopes

No landslide deposits in the vicinity of the Landfill are shown on any published geologic information and none have been identified during site visits (SHB-AGRA, 1994).

2.6.6.2 Karst

Several thousand feet of basin filling sediments occur beneath the Landfill. No limestone or other soluble units subject to karst formation exists in the vicinity (SHB-AGRA, 1994).

2.6.6.3 Subsidence

Subsidence has been documented in the El Paso metropolitan area as a result of groundwater withdrawal and subsequent decline in groundwater levels, especially in area having thick accumulations of clay in the subsurface. The Landfill is located in an area of documented groundwater withdrawal resulting in groundwater declines up to 40 feet (Ashworth 1990). No land surface subsidence has been documented in the vicinity of the Landfill (Land and Armstrong, 1985). Due to depth to groundwater, formation of large scale subsidence features is not anticipated, but cannot be precluded (SHB-AGRA, 1994)

2.6.6.4 Liquefaction

Since groundwater occurs at depths of 300-400 feet below land surface, no liquefaction concerns exist (SHB-AGRA, 1994).

2.7.1 Groundwater Conditions

Consistent with §330.61(k)(1), a discussion of groundwater conditions at and near the facility was prepared. Data pertaining to the hydrogeology of the area and groundwater beneath the Landfill are provided in the reports *Site Characterization and Monitoring Plan, McCombs Municipal Landfill, El Paso, Texas* included in Appendix 3K, Attachment 1 and *Groundwater Monitoring System Installation, City of El Paso McCombs Landfill* included in Appendix 3L, Attachment 1.

The regional groundwater system in the area primarily consists of the Hueco Bolson aquifers. The Hueco Bolson is divided into the City Artesian area, the Mesa area and the Lower Valley (Leggart, 1962). The Mesa area extends north of the City Artesian area into New Mexico and east to the Hueco Mountains. The Landfill is located within the Mesa area.

Two aquifers occur in these areas: an upper aquifer in the Rio Grande alluvium and a lower aquifer in the Hueco Bolson deposits. Since no known impermeable zone of regional extent separates these aquifers, the Rio Grande alluvium and the Hueco Bolson are considered to be, at least in part, hydrologically connected in the City Artesian and Lower Valley areas (Alvared and Buckner, 1980). The Mesa area primarily consists of Hueco Bolson deposits. Historic withdrawals of groundwater since 1906 for public water supply and irrigation have caused major declines in the water levels. The average water level decline in the Hueco Bolson from 1903 to 1980 is approximately 53 feet (White, 1987).

Locally, recharge to the aquifer occurs due to mountain front infiltration of precipitation from the surface and from the injection of treated sewage into the aquifer from the Hueco Bolson Recharge Project (White and Sladek, 1990). Numerous injection wells were constructed northeast of El Paso and water from the Fred Hervey Water Treatment Plant has been injected into the aquifer by El Paso Water Utilities (EPWU) since the mid-1980s. Since 1991, EPWU has been selling water to El Paso Electric Company for use as cooling water at the Newman Plant, thus less water has been injected into the aquifer (Sperka, 1993).

Based on available information, regional groundwater flow direction in the McCombs Landfill area is to the south-southeast. Groundwater movement in the area is generally less than 1.0 feet per day (White, 1987). EPWU groundwater data indicate that the static groundwater elevation in the area is between 3,670 and 3,675 feet MSL or approximately 370 to 390 feet below ground surface (EPWU, 1993).

Groundwater conditions at the site were determined using data from three groundwater monitoring wells constructed in 2003 around the landfill as part of the approved Subtitle D groundwater monitoring system. Water levels data from December 6, 2010

indicates ground water beneath the site occur approximately 390 to 398 feet below land surface, with corresponding elevations of 3,677 to 3,686 feet AMSI. Based on groundwater level measurements at the site, groundwater flow direction is S70° East or to the east-southeast.

Parkhill, Smith & Copper (PSC) completing an additional hydrogeologic evaluation for the Landfill that included the installation of two additional monitoring wells PZ-4 and PZ-5. Data collected from August 2011 through July 2012 indicate groundwater flow direction is predominately to the east/southeast, likely influenced by the drawdown from the Cemex well located near the southeast corner of the landfill and just north of Stan Roberts Road. The PSC report also notes a northwest component of groundwater flow in the southwest portion of the site.

The site-specific groundwater flow direction correlates with regional groundwater flow direction within the Hueco Bolson aquifer.

2.7.2 Surface Water Conditions

Surface water conditions for the development of the site was designed to be consistent with 30 TAC 330.61(k). The surface water drainage report and design is included in Section 3.3 – Facility Surface Water Drainage Report.

The Landfill is located in the city limits of El Paso and encompasses a total of 347 acres. The surrounding areas are generally unpopulated and are predominantly undeveloped, agricultural or industrial.

Currently, stormwater on site is directed away from active portions of the landfill by ditches designed for the 25-year storm event. The ditches direct water to the three onsite stormwater retention ponds. These ponds are designed to hold the 100-year storm event as well as contingency storage for sediment. Stormwater runoff is collected in a v-ditch around the perimeter of the landfill units and is directed into an existing stormwater pond on the southeastern corner. Runoff from north of the existing landfill is currently captured within the mined pit area. Some of the runoff in the northwest corner continues to the site of existing Retention Pond A. Runoff generated to the east is captured in the mined pit area. Runoff generated in the existing landfill areas is conveyed into existing Retention Pond D, west of the existing fee house, and existing Retention Pond E, in the southeastern corner of the developed landfill area. These exiting stormwater patterns are shown on Drawing P3-4, Existing Drainage Conditions, in Appendix 3C.

Four ponds will exist in the final cover condition. The final contours include four ponds to break up drainage areas (the existing Retention Ponds A and E, and Ponds B and C), and in effect reduce sheet flow and minimize erosion. Existing Pond D is no longer needed as that area is filled to grade and flow is conveyed in a v-ditch to Pond E. Perimeter ditches will be constructed as the landfill final contours are approached. These ditches will direct water to the retention ponds where they will retain the 100-year event and sediment. The landfill will provide care and management, both during construction and long term, of soil erosion and control of sediment due to surface water.

The care and management of soil erosion and sedimentation is outlined in Part III – Erosion and Sedimentation Control Plan. The facility will prevent discharge of pollutants to waters of the state. There are no waters of the United States or Corps of Engineers' jurisdictional waters of the state on site, therefore, no Section 404 permit is required. The Landfill submitted a notice of intent (NOI) to comply with the Texas Pollutant Discharge Elimination System (TPDES) Stormwater Permit relating to stormwater discharge and received Permit No. TX05L795 from the TCEQ on October 28, 2011. A copy of this permit is included in Appendix 2D – TPDES Multi-Sector General Permit.

2.8.1 Abandoned Water Wells

No known abandoned water wells exist within the permit boundary of the Landfill. Existing water wells are identified on the Land Use Map located in Appendix 2A – Maps and a description of each well is noted in Section 2.4.2.

If an abandoned water well is indentified, the City shall provide the executive director with a written certification that all such wells have been capped, plugged, and closed in accordance with all applicable rules and regulations of the commission or other state agency. This certification will be provided to the TCEQ within 30 days after the well has been properly plugged. If necessary, a permit modification will be submitted to the executive director if the identification of an abandoned water well affects the liner installation plan.

2.8.2 Abandoned Oil Wells

No abandoned crude oil or natural gas wells, or other wells associated with the mineral recover that are under the jurisdiction of the TRRC were found within the permit boundary at the Landfill. As noted in Section 2.4.2, a search of the TRRC oil and gas well database conducted in February of 2011 did not identify any existing oil or gas wells within the Landfill boundary or within 500 feet of the Landfill.

If an abandoned oil well is identified, the City shall provide the executive director with a written certification that all such wells have been properly capped, plugged, and closed in accordance with all applicable rules and regulations of the TRRC. This certification will be provided to the TCEQ within 30 days after the well has been properly plugged.

Section 2.9
FLOODPLAINS AND WETLANDS STATEMENT
30 TAC §330.61(m)

A floodplain restrictions and wetlands restrictions report was completed in June of 1994 by SHB AGRA Earth and Environmental (SHB) and is provided for reference in Appendix 3K, Attachment 4. Information from that report has been included in this statement to meet the requirements of 30 TAC §330.61(m).

2.9.1 Floodplains

According to 40 CFR §258.11**,** 30 TAC §330.307 and §330.547, "owners or operators of new MSWLF units, existing MSWLF units, and lateral expansions located in 100-year floodplains must demonstrate that the unit will not restrict the flow of the 100-year flood, reduce the temporary water storage capacity of the floodplain, or results in washout of solid waste so as to pose a hazard to human health and the environment."

As shown in the Federal Emergency Management Agency (FEMA) Flood Insurance Rate Map (FIRM) provided in Appendix 2E – Floodplains and Wetlands Documentation, a portion of the landfill is located within the 100-year floodplain. No waste disposal activities will occur in the section of the property lying within the 100-year floodplain. Instead, existing Retention Pond A has been designed to cover the area affected by the 100-year floodplain. Refer to Section 3.3 – Facility Surface Water Drainage Report for further details concerning the effects of the 100-year floodplain and the design of the stormwater detention ponds.

2.9.2 Wetlands

According to 30 TAC §330.553, new MSW landfill units, lateral expansions, and material recovery operations from a landfill shall not be located in wetlands, unless the owner or operator makes specific demonstrations to show that the landfill will not cause environmental harm.

Based on a 1982 map prepared by T.E. Dohl, the Landfill is not located in area designated as a wetland. This map is included in Appendix 2E – Floodplains and Wetlands Documentation.

Section 2.10
ENDANGERED SPECIES STATEMENT
30 TAC §330.61(n)

To meet the requirements of 30 TAC §330.61(n) and 30 TAC §330.551, a letter dated August 13, 1982 from the United States Fish and Wildlife Service (USFWS) has been included in Appendix 2F – Endangered Species Documentation. This letter was previously included in both the 1984 and 2002 permit amendment application submittals. Additionally, current correspondence between the Texas Parks and Wildlife Department (TPWD) and the U.S. Fish and Wildlife Service is also provided in Appendix 2F.

According to the 1982 USFWS letter, the American Peregrine Falcon may use the project site as a feeding area or pass through the area during migration. According to the information provided on the USFWS website, the American Peregrine Falcon was delisted from the federal endangered species list on August 25, 1999. However, the American Peregrine Falcon remains a State of Texas protected species. A copy of the USFWS species profile is also provided in Appendix 2F – Endangered Species Documentation.

As indicated in the USFWS letter, it is unlikely that the Landfill will have any effect on this species. However, if the American Peregrine Falcon were to be observed within the permitted landfill area, the employees will be instructed to follow the steps listed below:

1. Avoid contact with the bird;
2. Temporarily halt or move site operations to an area away from the bird's location to prevent disrupting the bird's activities while feeding or passing by the site;
3. Wait until the bird abandons the site on its own will; and
4. Resume normal site operations once the bird has taken flight.

In addition, Landfill personnel will be trained regarding the bird's physical characteristics and appearance in order to be able to identify it at once and with certainty during operations. This training will prevent unnecessary and unwarranted disruptions of site activities due to the presence of birds that may look similar to the American Peregrine Falcon.

According to the 2012 TPWD response letter, the following species have been listed as threatened or endangered under the Endangered Species Act (ESA) and have the potential to occur in El Paso County:

- Least Tern – Listed 08/28/1985
- Northern Aplomado Falcon – Listed 02/25/1986
- Mexican Spotted Owl – Listed 03/16/1993
- Southwestern Willow Flycatcher – Listed 02/27/1995

The following are state-listed threatened species that could potentially occur in the area:

- Texas Horned Lizard
- Mountain Short-Horned Lizard

The following are state-listed species of concern that could potentially occur in the area:

- Western Burrowing Owl
- Desert Night-Blooming Cereus

Further information regarding these species, their suitable habitats, and avoidance procedures are included in Appendix 2F.

Section 2.11
TEXAS HISTORICAL COMMISSION REVIEW
30 TAC §330.61(o)

As required by 30 TAC §330.61(o), a letter was submitted to the Texas Historical Commission to document compliance with the Natural Resources Code, Chapter 191, Texas Antiquities Code. This letter and the Texas Historical Commission response can be found in Appendix 2G – Texas Historical Commission Documentation.

2.12.1 Rio Grande Council of Governments

As per 30 TAC §330.61(p), Parts I and II of the permit amendment application were submitted for review to the Rio Grande Council of Governments (RGCOG) to determine compliance with the regional solid waste management plan. Documentation of coordination with RGCOG is provided in Appendix 2H – RGCOG Review.

2.12.2 City of El Paso

Because the City owns and operates the Landfill, this permit amendment application has been prepared to meet the City's solid waste needs and comply with the City's long-term solid waste management plan.

SAIC®

2.1.1 Existing Conditions Overview

The Landfill is located on approximately 347 acres in rural El Paso County, Texas and serves the greater City of El Paso area. The Landfill was originally permitted in 1976, with subsequent permitting to 327 acres in 1984. This MPA includes the addition of 19.4 acres to include the site entrance facilities within the permitted boundary. The development of the Landfill generally followed the progression of a sand and gravel quarry in that location.

The following summarizes the Landfill's permitting timeline from the TCEQ and its predecessors: Texas Natural Resource Conservation Commission (TNRCC) and the Texas Department of Health (TDH).

- **1976:** Original MSW Permit 729 issued by TDH.
- **1984:** Permit amendment completed to expand acreage from 25 acres to 327 acres. MSW Permit 729A was issued by TDH.
- **1995:** Alternative liner design approved.
- **2002:** Site Development Plan (SDP) permit modification completed.
- **2004:** Closure and post-closure care cost estimates updated.
- **2006:** Site Operating Plan (SOP) updated to comply with current regulations.
- **2009:** Landfill Gas Collection and Control System (GCCS) permit modification completed.
- **2009:** Groundwater Sampling and Analysis Plan permit modification completed.

The Landfill serves the MSW disposal needs of the City of El Paso area. This represents a metropolitan population of 620,456, according to 2009 projections from the United States Census Bureau. The Landfill also accepts waste from neighboring communities in El Paso County, Texas and from Doña Ana County, New Mexico.

As discussed in Section 1.1.2 – Supplementary Technical Report, ~~the City plans to return the Landfill to active status and begin accepting MSW in 2014~~ ***in 2005, the City ceased regular solid waste disposal activities, and the majority of the City's MSW was diverted to the City's Clint Landfill as well as private facilities. During this period, the Landfill was primarily used for the disposal of storm debris and material generated from street cleanings. The City estimates that the Clint Landfill will undergo final closure activities in 2030, and wishes to return the Landfill to full activities to meet immediate and future solid waste disposal needs.*** To account for the expected increase in waste, the City developed a vertical expansion of the existing Landfill from 4,125 feet MSL to 4,305 feet MSL to meet their solid waste disposal needs.

2.1.2 Permits and Authorizations

The following Table 2.1-1 summarizes the existing permits and authorizations for the Landfill.

Table 2.1-1
Current McCombs Landfill Permits and Authorizations

Permit Type	Permit Number
TCEQ Texas Pollutant Discharge Elimination System (TPDES) Stormwater Permit	TXR05L795
TCEQ Air New Source Permit	81742
TCEQ Subchapter U: Standard Air Permit	1749
TCEQ Wastewater General Permit	2E0000049

2.1.3 Site-Specific Conditions

In accordance with 30 TAC §330.61(a), a detailed discussion of the site-specific special conditions at the Landfill is included throughout Part II of this MPA application. Items discussed in Section 2.4 through Section 2.10 include the impact on the surrounding area, transportation, general geology and soils, groundwater and surface water, abandoned oil and water wells, floodplains and wetlands, and endangered or threatened species.

There are no existing site-specific conditions that require special design considerations or possible mitigation of conditions.

2.1.1 Existing Conditions Overview

The Landfill is located on approximately ***347*** ~~327~~ acres in rural El Paso County, Texas and serves the greater City of El Paso area. The Landfill was originally permitted in 1976, with subsequent permitting to ***327 acres*** ~~the current acreage~~ in 1984. ***This MPA includes the addition of 19.4 acres to include the site entrance facilities within the permitted boundary.*** The development of the Landfill generally followed the progression of a sand and gravel quarry in that location.

The following summarizes the Landfill's permitting timeline from the TCEQ and its predecessors: Texas Natural Resource Conservation Commission (TNRCC) and the Texas Department of Health (TDH).

- **1976:** Original MSW Permit 729 issued by TDH.
- **1984:** Permit amendment completed to expand acreage from 25 acres to 327 acres. MSW Permit 729A was issued by TDH.
- **1995:** Alternative liner design approved.
- **2002:** Site Development Plan (SDP) permit modification completed.
- **2004:** Closure and post-closure care cost estimates updated.
- **2006:** Site Operating Plan (SOP) updated to comply with current regulations.
- **2009:** Landfill Gas Collection and Control System (GCCS) permit modification completed.
- **2009:** Groundwater Sampling and Analysis Plan permit modification completed.

The Landfill serves the MSW disposal needs of the City of El Paso area. This represents a metropolitan population of 620,456, according to 2009 projections from the United States Census Bureau. The Landfill also accepts waste from neighboring communities in El Paso County, Texas and from Doña Ana County, New Mexico.

As discussed in Section 1.1.2 – Supplementary Technical Report, the City plans to return the Landfill to active status and begin accepting MSW in 2014. To account for the expected increase in waste, the City ***developed a vertical expansion of*** ~~proposes to vertically expand~~ the existing Landfill from 4,125 feet MSL to 4,305 feet MSL to meet their solid waste disposal needs.

2.1.2 Permits and Authorizations

The following Table 2.1-1 summarizes the existing permits and authorizations for the Landfill.

Table 2.1-1
Current McCombs Landfill Permits and Authorizations

Permit Type	Permit Number
TCEQ Texas Pollutant Discharge Elimination System (TPDES) Stormwater Permit	TXR05L795
TCEQ Air New Source Permit	81742
TCEQ Subchapter U: Standard Air Permit	1749
TCEQ Wastewater General Permit	2E0000049

2.1.3 Site-Specific Conditions

In accordance with 30 TAC §330.61(a), a detailed discussion of the site-specific special conditions at the Landfill is included throughout Part II of this MPA application. Items discussed in Section 2.4 through Section 2.10 include the impact on the surrounding area, transportation, general geology and soils, groundwater and surface water, abandoned oil and water wells, floodplains and wetlands, and endangered or threatened species.

There are no existing site-specific conditions that require special design considerations or possible mitigation of conditions.

2.1.1 Existing Conditions Overview

The Landfill is located on approximately 327 acres in rural El Paso County, Texas and serves the greater City of El Paso area. The Landfill was originally permitted in 1976, with subsequent permitting to the current acreage in 1984. The development of the Landfill generally followed the progression of a sand and gravel quarry in that location.

The following summarizes the Landfill's permitting timeline from the TCEQ and its predecessors: Texas Natural Resource Conservation Commission (TNRCC) and the Texas Department of Health (TDH).

- **1976:** Original MSW Permit 729 issued by TDH.
- **1984:** Permit amendment completed to expand acreage from 25 acres to 327 acres. MSW Permit 729A was issued by TDH.
- **1995:** Alternative liner design approved.
- **2002:** Site Development Plan (SDP) permit modification completed.
- **2004:** Closure and post-closure care cost estimates updated.
- **2006:** Site Operating Plan (SOP) updated to comply with current regulations.
- **2009:** Landfill Gas Collection and Control System (GCCS) permit modification completed.
- **2009:** Groundwater Sampling and Analysis Plan permit modification completed.

The Landfill serves the MSW disposal needs of the City of El Paso area. This represents a metropolitan population of 620,456, according to 2009 projections from the United States Census Bureau. The Landfill also accepts waste from neighboring communities in El Paso County, Texas and from Doña Ana County, New Mexico.

As discussed in Section 1.1.2 – Supplementary Technical Report, the City plans to return the Landfill to active status and begin accepting MSW in 2014. To account for the expected increase in waste, the City proposes to vertically expand the existing Landfill from 4,125 feet MSL to 4,305 feet MSL to meet their solid waste disposal needs.

2.1.2 Permits and Authorizations

The following Table 2.1-1 summarizes the existing permits and authorizations for the Landfill.

Table 2.1-1
Current McCombs Landfill Permits and Authorizations

Permit Type	Permit Number
TCEQ Texas Pollutant Discharge Elimination System (TPDES) Stormwater Permit	TXR05L795
TCEQ Air New Source Permit	81742
TCEQ Subchapter U: Standard Air Permit	1749
TCEQ Wastewater General Permit	2E0000049

2.1.3 Site-Specific Conditions

In accordance with 30 TAC §330.61(a), a detailed discussion of the site-specific special conditions at the Landfill is included throughout Part II of this MPA application. Items discussed in Section 2.4 through Section 2.10 include the impact on the surrounding area, transportation, general geology and soils, groundwater and surface water, abandoned oil and water wells, floodplains and wetlands, and endangered or threatened species.

There are no existing site-specific conditions that require special design considerations or possible mitigation of conditions.

2.2.1 Sources and Characteristics of Waste

The majority of the waste that will be accepted by the Landfill will be classified as MSW (defined in 30 TAC §330.3(88)). MSW accepted in the lined portion of the Landfill will be typically generated from household, residential, commercial, institutional, municipal, manufacturing, industrial, recreational, and construction-demolition sources.

The Landfill also intends to accept construction and demolition (C&D) waste on top of the existing unlined landfill that will consist of (Class 3 like) inert wastes. More specifically, C&D waste will consist of (but is not limited to):

- Rock/stone;
- Concrete;
- Uncontaminated soil;
- Masonry (brick, stucco and plaster);
- ~~Siding (vinyl, masonite, aluminum, and steel);~~
- ***Aluminum[1];*** ~~Duct work;~~
- ~~Plumbing fixtures;~~
- Ceramic items;
- Conduit and pipes ***(free of asbestos)***;
- Glass;
- Inert Plastics ***(any voids in materials accepted will be removed upon waste compaction)***;
- Molded fiberglass; ***and***
- ~~Rubber;~~
- Metal***.[1]***;
- ~~Vinyl flooring; and~~
- ~~Similar materials that are not readily decomposable.~~

The Landfill will also accept several types of special wastes as described in the Special Waste Acceptance Plan included in Part IV – Site Operating Plan. Acceptable special wastes include Class II industrial waste and municipal commercial waste such

[1] For C&D material to be used within the area of the piggyback liner profile (referred throughout as Scenario 3), metals (including aluminum) shall be limited to incidental amounts (no more than 5% per load).

as treated medical waste, processed grease/grit trap waste, dead animals, slaughterhouse wastes, and petroleum-product or crude oil contaminated soil. The Landfill also intends to accept regulated asbestos containing material (RACM) as described in Section 4.9.22.

As per 30 TAC §330.15, the Landfill will not accept hazardous wastes for disposal. These hazardous wastes include lead acid storage batteries, do-it-yourself motor vehicle oil, used oil filters, whole used or scrap tires, refrigerators, freezers, air conditioners, and other items containing chlorinated fluorocarbons (CFCs), bulk or non-containerized liquid waste, regulated hazardous waste as defined in 30 TAC §330.3, polychlorinated biphenyl (PCB) wastes, and radioactive materials.

Specific information regarding the movement of these wastes through the Landfill is discussed in Section 3.2.2.

2.2.2 Projected Waste Acceptance Rates

The Landfill will serve the communities, businesses and institutions in and around the City of El Paso, Texas. The facility ceased regular solid waste disposal activities in 2005 and has only received minimal waste from storm events and street cleanings in the past 5 years. This amounted to approximately 3,785 tons in FY 2010.

The Landfill will continue accepting only minimal waste from 2011 through 2013. Based on research of the current waste stream and conversations with City staff, SAIC estimates that the Landfill may receive approximately 497,309 tons per year (TPY) starting in 2014. In general, this acceptance rate will likely increase over the life of the Landfill due to an expected increase in the population served, but may vary due to conditions in the solid waste market.

The estimated maximum annual waste acceptance rate for the Landfill projected for five years is summarized in Table 2.2-1.

Table 2.2-1
Estimated Maximum Annual Waste Acceptance
(FY 2011 to FY 2015)

FY	Estimated Maximum Waste Acceptance Rate (Tons)
2011	3,000
2012	3,000
2013	3,000
2014	497,309
2015	507,255

Once the vertical expansion is approved, the Landfill will have a remaining disposal capacity of approximately ***62,853,182*** ~~62,532,764~~ cubic yards (CY) of soil and waste. This will allow the Landfill to have adequate capacity through approximately 2059, assuming that the City's Clint Landfill undergoes closure in the year 2030 and all of the City's MSW disposal needs are met by the McCombs Landfill.

2.2.3 Population Equivalent

According to 30 TAC §330.3, the population equivalent is defined as the hypothetical population that would generate an amount of solid waste equivalent to that actually being managed based on a generation rate of five pounds per capita per day and applied to situations involving solid waste not necessarily generated by individuals. It is assumed, for the purpose of this section, that the average volume per ton of waste entering a municipal solid waste disposal facility is three cubic yards. The projected population equivalent for the Landfill is calculated in Table 2.2-2.

Table 2.2-2
Projected Population Equivalent for McCombs Landfill

	2012	2020	2030	2040
Waste Accepted (ton/yr)	3,000	560,050	1,517,107	1,849,345
Waste Accepted (ton/day)[1]	8.219	1,534	4,156	5,067
Waste Accepted (lb/day)[2]	16,438	3,068,767	8,312,915	10,133,397
Population Equivalent[3]	3,288	613,753	1,662,583	2,026,679

1. Assumes waste generation 365 days per year.
2. Assumes 2,000 lb per ton.
3. Assumes per capita generation rate of 5 pounds as per 30 TAC §330.3.

2.2.1 Sources and Characteristics of Waste

The majority of the waste that will be accepted by the Landfill will be classified as MSW~~. As~~ ***(***defined in 30 TAC §330.3***(88))***~~, MSW includes waste resulting from or incidental to municipal, community, commercial, institutional, and recreational activities, including garbage, rubbish, ashes, street cleanings, dead animals, abandoned automobiles, and all other solid waste other than industrial solid waste~~. ***MSW accepted in the lined portion of the Landfill will be typically generated from household, residential, commercial, institutional, municipal, manufacturing, industrial, recreational, and construction-demolition sources.***

The Landfill also intends to accept construction and demolition (C&D) waste on top of the existing unlined landfill that will consist of (Class 3 like) inert wastes. More specifically, C&D waste will consist of (but is not limited to):

- ***Rock/stone;***
- ***Concrete;***
- ***Uncontaminated soil;***
- ***Masonry (brick, stucco and plaster);***
- ***Siding (vinyl, masonite, aluminum, and steel);***
- ***Duct work;***
- ***Plumbing fixtures;***
- ***Ceramic items;***
- ***Conduit and pipes;***
- ***Glass;***
- ***Inert Plastics;***
- ***Molded fiberglass;***
- ***Rubber;***
- ***Metal;***
- ***Vinyl flooring; and***
- ***Similar materials that are not readily decomposable.***

The Landfill will also accept several types of special wastes as described in the Special Waste Acceptance Plan included in Part IV – Site Operating Plan. Acceptable special wastes include Class II industrial waste and municipal commercial waste such as treated medical waste, processed grease/grit trap waste, dead animals, slaughterhouse wastes, and petroleum-product or crude oil contaminated soil. The

Landfill also intends to accept regulated asbestos containing material (RACM) as described in Section 4.9.22. ~~No Class I industrial solid waste will be accepted at the Landfill.~~

As per 30 TAC §330.15, the Landfill will not accept hazardous wastes for disposal. These hazardous wastes include lead acid storage batteries, do-it-yourself motor vehicle oil, used oil filters, whole used or scrap tires, refrigerators, freezers, air conditioners, and other items containing chlorinated fluorocarbons (CFCs), bulk or non-containerized liquid waste, regulated hazardous waste as defined in 30 TAC §330.3, polychlorinated biphenyl (PCB) wastes, and radioactive materials.

Specific information regarding the movement of these wastes through the Landfill is discussed in Section 3.2.2.

2.2.2 Projected Waste Acceptance Rates

The Landfill will serve the communities, businesses and institutions in and around the City of El Paso, Texas. The facility ceased regular solid waste disposal activities in 2005 and has only received minimal waste from storm events and street cleanings in the past 5 years. This amounted to approximately 3,785 Tons in FY 2010.

The Landfill will continue accepting only minimal waste from 2011 through 2013. Based on research of the current waste stream and conversations with City staff, SAIC estimates that the Landfill may receive approximately 497,309 tons per year (TPY) starting in 2014. In general, this acceptance rate will likely increase over the life of the Landfill due to an expected increase in the population served, but may vary due to conditions in the solid waste market.

The estimated maximum annual waste acceptance rate for the Landfill projected for five years is summarized in Table 2.2-1.

Table 2.2-1
Estimated Maximum Annual Waste Acceptance
(FY 2011 to FY 2015)

FY	Estimated Maximum Waste Acceptance Rate (Tons)
2011	3,000
2012	3,000
2013	3,000
2014	497,309
2015	507,255

Once the vertical expansion is approved, the Landfill will have a remaining disposal capacity of approximately 62,532,764 cubic yards (CY) of soil and waste. This will allow the Landfill to have adequate capacity through approximately 2059, assuming that the City's Clint Landfill undergoes closure in the year 2030 and all of the City's MSW disposal needs are met by the McCombs Landfill.

2.2.3 Population Equivalent

According to 30 TAC §330.3, the population equivalent is defined as the hypothetical population that would generate an amount of solid waste equivalent to that actually being managed based on a generation rate of five pounds per capita per day and applied to situations involving solid waste not necessarily generated by individuals. It is assumed, for the purpose of this section, that the average volume per ton of waste entering a municipal solid waste disposal facility is three cubic yards. The projected population equivalent for the Landfill is calculated in Table 2.2-2.

Table 2.2-2
Projected Population Equivalent for McCombs Landfill

	2012	2020	2030	2040
Waste Accepted (ton/yr)	3,000	560,050	1,517,107	1,849,345
Waste Accepted (ton/day)[1]	8.219	1,534	4,156	5,067
Waste Accepted (lb/day)[2]	16,438	3,068,767	8,312,915	10,133,397
Population Equivalent[3]	3,288	613,753	1,662,583	2,026,679

1. Assumes waste generation 365 days per year.
2. Assumes 2,000 lb per ton.
3. Assumes per capita generation rate of 5 pounds as per 30 TAC §330.3.

2.2.1 Sources and Characteristics of Waste

The majority of the waste that will be accepted by the Landfill will be classified as MSW. As defined in 30 TAC §330.3, MSW includes waste resulting from or incidental to municipal, community, commercial, institutional, and recreational activities, including garbage, rubbish, ashes, street cleanings, dead animals, abandoned automobiles, and all other solid waste other than industrial solid waste.

The Landfill will also accept several types of special wastes as described in the Special Waste Acceptance Plan included in Part IV – Site Operating Plan. Acceptable special wastes include Class II industrial waste and municipal commercial waste such as treated medical waste, processed grease/grit trap waste, dead animals, slaughterhouse wastes, and petroleum-product or crude oil contaminated soil. The Landfill also intends to accept regulated asbestos containing material (RACM) as described in Section 4.9.22. No Class I industrial solid waste will be accepted at the Landfill.

Specific information regarding the movement of these wastes through the Landfill is discussed in Section 3.2.2.

2.2.2 Projected Waste Acceptance Rates

The Landfill will serve the communities, businesses and institutions in and around the City of El Paso, Texas. ***The facility ceased regular solid waste disposal activities in 2005 and has*** ~~Because the Landfill has been inactive since 2005,~~ only ***received*** minimal waste from storm events and street cleanings ~~have been received~~ in the past 5 years. This amounted to approximately 3,785 Tons in FY 2010.

The Landfill will continue accepting only minimal waste from 2011 through 2013. Based on research of the current waste stream and conversations with City staff, SAIC estimates that the Landfill may receive approximately 497,309 tons per year (TPY) starting in 2014. In general, this acceptance rate will likely increase over the life of the Landfill due to an expected increase in the population served, but may vary due to conditions in the solid waste market.

The estimated maximum annual waste acceptance rate for the Landfill projected for five years is summarized in Table 2.2-1.

Table 2.2-1
Estimated Maximum Annual Waste Acceptance
(FY 2011 to FY 2015)

FY	Estimated Maximum Waste Acceptance Rate (Tons)
2011	3,000
2012	3,000
2013	3,000
2014	497,309
2015	507,255

Once the vertical expansion is approved, the Landfill will have a remaining disposal capacity of approximately 62,532,764 cubic yards (CY) of soil and waste. This will allow the Landfill to have adequate capacity through approximately ***2059***~~2060~~, assuming that the City's Clint Landfill undergoes closure in the year 2030 and all of the City's MSW disposal needs are met by the McCombs Landfill.

2.2.3 Population Equivalent

According to 30 TAC §330.3, the population equivalent is defined as the hypothetical population that would generate an amount of solid waste equivalent to that actually being managed based on a generation rate of five pounds per capita per day and applied to situations involving solid waste not necessarily generated by individuals. It is assumed, for the purpose of this section, that the average volume per ton of waste entering a municipal solid waste disposal facility is three cubic yards. The projected population equivalent for the Landfill is calculated in Table 2.2-2.

Table 2.2-2
Projected Population Equivalent for McCombs Landfill

	2012	2020	2030	2040
Waste Accepted (ton/yr)	3,000	560,050	1,517,107	1,849,345
Waste Accepted (ton/day)[1]	8.219	1,534	4,156	5,067
Waste Accepted (lb/day)[2]	16,438	3,068,767	8,312,915	10,133,397
Population Equivalent[3]	3,288	613,753	1,662,583	2,026,679

1. Assumes waste generation 365 days per year.
2. Assumes 2,000 lb per ton.
3. Assumes per capita generation rate of 5 pounds as per 30 TAC §330.3.

2.3.1 General Location Maps

As required by 30 TAC §330.61(c), general location maps have been provided in Appendix 2A - Maps. These maps have been provided in addition to those required by 30 TAC §330.59(c) relating to contents in Part I of the application and present information on the general character of the surrounding land. ***The required information per 30 TAC §330.61(c) and the information location within the report is summarized below:***

> ***"1) the prevailing wind direction with a wind rose;"***

The wind rose provided from TCEQ is shown on Drawing P1-3 (Appendix 1A). The wind rose period of record is from 1984 to 1992. The wind rose frequency of occurrence of winds is plotted in the sixteen points of the compass, with a maximum of six wind speed classes for each direction.

> ***"2) all known water wells within 500 feet of the proposed permit boundary with the state well numbering system designation for Water Development Board "located wells";"***

Known water wells within 500-feet are provided in Section 2.4.2.

> ***"3) all structures and inhabitable buildings within 500 feet of the proposed facility;"***

Three buildings were identified within 500-feet of the facility boundary. These buildings include the CEMEX Quarry office and scale house and site trailers.

> ***"4) schools, licensed day-care facilities, churches, hospitals, cemeteries, ponds, lakes, and residential, commercial, and recreational areas within one mile of the facility;"***

Drawing P2-3 provides a land use map for the Landfill within one mile of the facility. Residential, commercial, and recreational areas are shown within this boundary. Table 2.4B-1 also provides a breakdown of the areas within the one mile radius by land use. Additionally, as stated, there are no schools, licensed day-care facilities, churches, hospitals, cemeteries or lakes within one mile of the Landfill. One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.

> ***"5) the location and surface type of all roads within one mile of the facility that will normally be used by the owner or operator for entering or leaving the facility;"***

The three main roads to be used by the facility (McCombs St, Stan Roberts Sr. Ave, and State Line Drive; locations shown on P2-1) are two-lane asphalt paved roads.

" 6) latitudes and longitudes;"

The latitudes and longitudes of the facility are provided on Drawings P2-1 and P2-2.

"7) area streams;"

There were not any streams identified within a 1-mile radius of the facility.

"8) airports within six miles of the facility;"

Airport locations within the vicinity of the facility are provided in Drawing P2-4.

"9) the property boundary of the facility;"

The property boundary is shown on several drawings included in Appendix 2A.

"10) drainage, pipeline, and utility easements within or adjacent to the facility;"

Facility easements are provided on Drawing P2-7 and are also discussed in Section 4.9.6.

"11) facility access control features; and"

Access to the Landfill is restricted by an existing barbed wire fence located along the perimeter of the facility as well as a locking gate at the facility entrance as depicted on Drawing P2-7.0 and as described in Section 3.2.1.

"12) archaeological sites, historical sites, and sites with exceptional aesthetic qualities adjacent to the facility."

As stated in Appendix 2B – Land Use Analysis, Page 2B-3, no archaeologically significant sites, historical sites, or locations of exceptional aesthetic quality were located within one-mile of the Landfill.

2.3.2 Facility Layout Maps

Facility layout maps have been provided in Appendix 2A - Maps, as per the requirements set forth in 30 TAC §330.61(d). These maps have been prepared to show the outline of the landfill units, general locations of the main interior facility roadways, locations of monitoring wells, locations of buildings, fencing, natural windbreaks, site entrance roads, and a delineation of the landfill sectors including sequencing of excavation and filling activities.

Existing earthen berms along the western and northern boundaries of the Landfill provide a method of visual screening for the facility.

2.3.3 General Topographic Map

Consistent with the regulations set forth in 30 TAC §330.61(e), United States Geologic Survey (USGS) 7 ½ minute quadrangle sheets for El Paso County have been provided to show the topography of the site. This general topographic map is

provided in Appendix 2A – Maps and is shown at a scale of one inch equals 2,000 feet.

2.3.4 Aerial Photograph

A series of aerial photographs have been provided in Appendix 2A – Maps as Drawings P2-5 and P2-6. Drawing P2-5 is from an aerial survey completed in February 2011 by Cooper Aerial Surveys Company. This aerial survey was utilized to determine the existing topography at the site. Drawing P2-6 has been provided from Google Earth to meet the requirements set forth in 30 TAC §330.61(f). This aerial photograph has a scale of ***approximately 1,050 feet*** ~~(between 1,667 and 3,334 feet)~~ equals one inch and shows the area within a one mile radius of the Landfill. This Google Earth image is based on source data from the Texas Ortho Imagery Program and the United States Department of Agriculture (USDA) from April 1, 2008 to June 13, 2010.

2.3.5 Land Use Map

As per the requirements in 30 TAC §330.61(g), a land use map has been provided in Appendix 2A – Maps. This map has been prepared using county-provided parcel data from El Paso County, Texas and Doña Ana County, New Mexico to depict land uses within one mile of the Landfill. A detailed written examination of this parcel data can be found in Appendix 2B – Land Use Analysis.

2.5.1 Overview

Consistent with the requirements set forth in 30 TAC §330.61(i), a Traffic Impact Analysis (TIA) was conducted by the City's Department of Transportation for the area immediately surrounding the Landfill. This TIA is included as Appendix 2C – Transportation Study and provides data on:

- The availability and adequacy of access roads for the site;
- Volume of vehicular traffic on access roads within one mile of the ~~proposed~~ facility, both existing and expected, during the life of the ~~proposed~~ facility; and
- The expected traffic volume to be generated by the facility on the access roads within one mile of the ~~proposed~~ facility.

Documentation of coordination between the City and Edgar E. Fino from the Texas Department of Transportation (TxDOT) concerning the ***future*** ~~proposed~~ roadway improvements and traffic and location restrictions is provided in Appendix 2C – Transportation Report.

2.5.2 Airport Safety

Pursuant to 30 TAC §330.61(i)(5), an evaluation of the facility was completed in accordance with 30 TAC §330.545(a). The identified airports within the general vicinity of the Landfill are provided in Appendix 2A – Maps. The Biggs Army Airfield was identified as being located approximately 9 miles from the Landfill and the El Paso International Airport was identified as being located approximately 11 miles from the Landfill. Additionally, correspondence was submitted to the Federal Aviation Administration to ensure that the Landfill is not:

1. Located within 10,000 feet of any airport runway end used by turbojet aircraft;
2. Within 5,000 feet of any airport runway end used by only piston-type aircraft;
3. Within a six mile radius of any small general service airport runway end used by turbojet or piston-type aircraft; or
4. Within a five mile radius of any large general public commercial airport runway end used by turbojet or piston-type aircraft.

Documentation of this correspondence is also provided in Appendix 2C.

2.5.1 Overview

Consistent with the requirements set forth in 30 TAC §330.61(i), a Traffic Impact Analysis (TIA) was conducted by the City's Department of Transportation for the area immediately surrounding the Landfill. This TIA is included as Appendix 2C – Transportation Study and provides data on:

- The availability and adequacy of access roads for the site;
- Volume of vehicular traffic on access roads within one mile of the proposed facility, both existing and expected, during the life of the proposed facility; and
- The expected traffic volume to be generated by the facility on the access roads within one mile of the proposed facility.

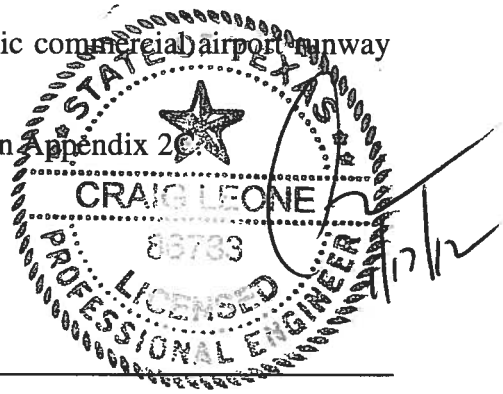
Documentation of coordination between the City and Edgar E. Fino from the Texas Department of Transportation (TxDOT) concerning the proposed roadway improvements and traffic and location restrictions is provided in Appendix 2C – Transportation Report.

2.5.2 Airport Safety

Pursuant to 30 TAC §330.61(i)(5), an evaluation of the facility was completed in accordance with 30 TAC §330.545 (a). The identified airports within the general vicinity of the Landfill are provided in Appendix 2A – Maps. The Biggs Army Airfield was identified as being located approximately 9 miles from the Landfill and the El Paso International Airport was identified as being located approximately 11 miles from the Landfill. Additionally, correspondence was submitted to the Federal Aviation Administration to ensure that the Landfill is not:

1. Located within 10,000 feet of any airport runway end used by turbojet aircraft;
2. Within 5,000 feet of any airport runway end used by only piston-type aircraft;
3. Within a six mile radius of any small general service airport runway end used by turbojet or piston-type aircraft; or
4. Within a five mile radius of any large general public commercial airport runway end used by turbojet or piston-type aircraft.

Documentation of this correspondence is also provided in Appendix 2C.



Consistent with §330.61(j)(1)-(4), a general discussion of the geology and soils of the site has been prepared. Detailed discussion of the geology of the site can be found in Section 3.5 of this application. This statement was prepared based on documents submitted for the McCombs Landfill ~~and presented in *McCombs Landfill MSW Permit No. 729A, Site Development Plan Permit Modification*~~ ***in previous permit modifications with referenced documents provided in the appendices of this major permit amendment.***

2.6.1 Topography

The original topography of the site was likely hilly. Subsequent quarrying and landfilling operations have significantly modified the natural conditions of the site. The present topography is dominated by large depressions; remnants of the quarrying operations that may range up to 30 feet deep. The landfill areas are ***currently*** built-up to elevations over 40 feet above land surface.

2.6.2 General Geology[1]

The McCombs Landfill is located within the Rio Grande Rift portion of the Mexican Highlands section of the Basin and Range Physiographic Province (Fnneman, 1931 and Thornbury, 1965). The Mexican Highlands Section is an area of variable geologic structure characterized by high desert valleys and mountain ranges and is subdivided into the Bolson and Rio Grande subsections (Hawley, 1975). The Bolson Subsections cover a large area of southwestern New Mexico, portions of Texas, Chihuahua, Mexico and Arizona. This region is characterized by broad intermontane basins with internal drainage, called bolsons, that are bounded by fault-block mountain ranges.

The mountain ranges on the eastern side of the Bolson subsection trend in a general north-to-northwest direction and typically flank sizeable basins, including the Hueco Bolson in which the site is located (Thornbury, 1965). The Rio Grande Valley in incised into thick deposits of basin fill at the southern end of the Hueco Bolson typically ranging in age from Pliocene to Holocene. A broad alluvial plain with gently sloping terraces characterize the valley of the Rio Grande River.

Tectonic basin formation began in the region in the early Miocene. With basin development, erosion and subsequent deposition of the Santa Fe Group sediments occurred (Gile, et al, 1981; Strain, 1966). Renewed faulting in Late Miocene and Pliocene time, coupled with uplift, produced a series of en echelon grabens, such as the Mesilla and Hueco Bolson that characterize this section of the Rio Grande Rift Valley. These bolsons received several thousands of feet of sediment during the Late

[1] Site Characterization and Monitoring Plan, McCombs Municipal Landfill, El Paso, Texas, SHB-AGRA, October 1993 ***(Appendix 3K, Attachment 1)***

Cenozoic (Strain, 1966). The ancestral Rio Grande River flowed into the closed basins in the area during the Pliestocene depositing thick sequences of sediment and forming an ephemeral lake (Strain, 1969).

The Hueco Bolson deposits were divided into two rock stratigraphic units, the Fort Hancock Formation and the Camp Rice Formation (Strain, 1969). The older Fort Hancock Formation is a massive unit composed of poorly consolidated clays, silt and fine-grained sands. In the early Pleistocene time, adjacent basins aggraded to levels sufficient to coalesce with the Hueco Bolson. Periods of high precipitation resulted in the formation of a large ephemeral lake system, Lake Cabeza de Vaca (Strain, 1966). Deposits of fine-grained sediments in the Hueco Bolson continued until an outlet to the southeast formed in the early Pliestocene. This outlet breached Lake Cabeza de Vaca and changed the depositional environment from predominantly lacustrine to fluvial (Strain, 1980).

The Camp Rice Formation unconformably overlies the Fort Hancock Formation and is primarily composed of gravel, sand, silt and occasional discontinuous lenses of volcanic ash. The Camp Rice Formation is composed of two basic subdivisions, a fluvial and a piedmont facies (Gile, et al, 1981). The fluvial facies is chiefly sand to pebbly river-channel deposits with subordinate fine-grained overbank units. This facies thickens toward the bolson axes and commonly wedges out against the piedmont facies. The permitted landfill area is probably underlain by fluvial deposits of the Camp Rice Formation.

2.6.3 General Soils

The McCombs Landfill is located on deposits of the Hueco Bolson, probably Camp Rice Formation. These deposits primarily consist of clay, sand, and gravel, with some caliche. The landfill site is underlain by Tertiary and Quaternary basin (bolson) deposits, overlain by areas of gravel and caliche rimrock. Recent Quaternary alluvial deposits are also present in the landfill vicinity in topographically low areas.

Boring logs for wells drilled on site to depths greater than 500 feet generally indicate deposits of:

- 0 – 50 feet Sand, and sand and gravel;
- 50-250 feet Sand, with some clay;
- 250-470 feet Sand and fine gravel mix; and
- 470-560 feet Sandy clay.

In general, the relatively clean sands are non-plastic, while sandy clay ranges from low to high plasticity. Permeability tests were not considered necessary based on the soil types encountered during the site characterization. Estimated coefficients of permeability are between 0.01 and 0.04 centimeters per second.

Manager Hydrogeology
Texas Licensed Professional Geoscientist No. 529
Expires September 30, 2012

2.6.4 Fault Areas[2]

The fault area restriction states that no new landfill units or lateral expansions can be placed within 200 feet of a fault that has experienced Holocene displacement. This restriction provides for minimal setbacks from actual fault traces since faults can result in damage to the landfill's integrity through:

- Movement along the fault causing displacement;
- Seismic activity associated with faulting resulting in seismic shaking of facility structures; and
- Seismic shaking resulting in slope failures.

The original permit states that "…an Eastern Boundary Fault Zone exists between the Franklin Mountains and the Hueco Bolson deposits" and "…assuming continuous movement this (movement of the fault) would equate to approximately 0.005 inches per year" (DRA, 1984).

Since several Quaternary faults have been identified within and at the margins of the Hueco Bolson, SHB reviewed recent published geologic mapping and literature to evaluate the proximity and age of known faults in the vicinity of the McCombs Landfill.

Numerous fault scarps of Quaternary age are preset in the Hueco Bolson near the Landfill. One inferred scarp apparently traverses the northeastern quadrant of the Landfill permit area (SHB, 1993). This fault was not identified on the geologic map prepared by Harbour (1972). Insufficient information is available to confirm or refute the presence of the fault. This fault is more than 200 feet from any existing or proposed Landfill units. Other north-south trending scarps are also apparent in the area.

The age of faulting in Hueco Bolson has been dated as less than 0.5 million years (m.y.), based on offset in the Camp Rice Formation and in soils formed on the Camp Rice formation (Seager 1980). A report by Collins and Raney (1991), indicates that those faults near the site displace deposits of middle Pliestocene age (approximately 200,000 to 900,000 years old). Evidence of displacement of younger deposits have not been documented either because younger sediments do not exist along the fault traces or have been covered by windblown sand. Collins and Raney (1991) point out that movement on the basin bounding the East Franklin Mountains located a few miles to the west of the landfill may be as young as Holocene. Other basin bounding faults and some of the intragraben faults (such as those near the Landfill) most

[2] Evaluation of Location Restrictions, McCombs Landfill, El Paso, Texas, SHB-AGRA June 1994 ***(Appendix 3K, Attachment 4)***

recently experienced rupture during the middle to late Pliestocene. More precise dating of the faults has not been performed, however, it is apparent that the faults have recurrence intervals of more than 10,000 years; otherwise the fault traces would be more clearly defined.

2.6.5 Seismic Impact Zones[2]

The seismic impact zone restrictions ***(30 TAC §330.557)*** states that "New municipal solid waste landfill (MSWLF) units and lateral expansions shall not located in seismic impact zones, unless the owner or operator demonstrates to the Director that all containment structures, including liners, leachate collection systems, and surface water control systems, are designed to resist the maximum horizontal acceleration in lithified earth materials for the site."

Under this regulation, a seismic risk zone is considered to be an area that has a 10 percent or more probability that the maximum horizontal acceleration in lithified material, expressed as a percentage of the earth's gravitational pull (g), will not exceed 0.10g in 250 years.

This regulation pertains to new MSWLF units and lateral expansions. This permit modification is a vertical expansion of the existing permitted Landfill and no new horizontal area will be opened under this permit modification. Based on the work completed by SHB-AGRA (1994) a review of USGS Miscellaneous Field Study Map MF-2121, "Probabilistic Earthquake Acceleration and Velocity Maps for the United States and Puerto Rico", (Algermissen, et. al, 1991) was conducted. El Paso County (and the Landfill) fall outside of any designated seismic impact zone.

The map on Figure 2-1 is from the USGS website:

http://earthquake.usgu.gov/research/hazmap/

Based on 2008 revised data, this map demonstrates the facility is located within a seismic impact zone and exceeds the 30 TAC §330.557 standard of 10 percent or more probability. The seismic impact zone restrictions only apply to new MSWLF units and lateral expansions. The permit modification for the Landfill is for a vertical expansion and no previously-undisturbed earth will be added to the Landfill boundary.

2.6.6 Unstable Areas

Consistent with 330.61(j)(4) and 330.559, unstable areas documentation was prepared and part of the application to demonstrate that the Landfill meets the location restriction for unstable area.

TCEQ regulations require the owner or operators of new MSWLF units, existing MSWLF units and lateral expansions located in an unstable area shall demonstrate that engineering measures have been incorporated into the MSWLF unit's design to ensure that the integrity of the structural components of the MSWLF unit will not be disrupted.

An unstable area is defined by TCEQ as a location that is susceptible to natural or human-induced events or forces capable of impairing the integrity of some or all of the

landfill's structural components responsible for preventing releases from a landfill. An unstable area can exhibit poor foundation conditions, area susceptible to mass movement, and karst terrains.

2.6.6.1 Unstable Slopes

No landslide deposits in the vicinity of the Landfill are shown on any published geologic information and none have been identified during site visits (SHB-AGRA, 1994).

2.6.6.2 Karst

Several thousand feet of basin filling sediments occur beneath the Landfill. No limestone or other soluble units subject to karst formation exists in the vicinity (SHB-AGRA, 1994).

2.6.6.3 Subsidence

Subsidence has been documented in the El Paso metropolitan area as a result of groundwater withdrawal and subsequent decline in groundwater levels, especially in area having thick accumulations of clay in the subsurface. The Landfill is located in an area of documented groundwater withdrawal resulting in groundwater declines up to 40 feet (Ashworth 1990). No land surface subsidence has been documented in the vicinity of the Landfill (Land and Armstrong, 1985). Due to depth to groundwater, formation of large scale subsidence features is not anticipated, but cannot be precluded (SHB-AGRA, 1994)

2.6.6.4 Liquefaction

Since groundwater occurs at depths of 300-400 feet below land surface, no liquefaction concerns exist (SHB-AGRA, 1994).

2.7.1 Groundwater Conditions

Consistent with §330.61(k)(1), a discussion of groundwater conditions at and near the facility was prepared. Data pertaining to the hydrogeology of the area and groundwater beneath the Landfill are provided in the reports *Site Characterization and Monitoring Plan, McCombs Municipal Landfill, El Paso, Texas* ~~(SHB-AGRA, 1993)~~ included in Appendix 3K, Attachment 1 and *Groundwater Monitoring System Installation, City of El Paso McCombs Landfill ~~Permit No. MSW-729A~~* ~~(Raba-Kistner, 2003)~~ included in Appendix 3L, Attachment 1.

The regional groundwater system in the area primarily consists of the Hueco Bolson aquifers. The Hueco Bolson is divided into the City Artesian area, the Mesa area and the Lower Valley (Leggart, 1962). The Mesa area extends north of the City Artesian area into New Mexico and east to the Hueco Mountains. The Landfill is located within the Mesa area.

Two aquifers occur in these areas: an upper aquifer in the Rio Grande alluvium and a lower aquifer in the Hueco Bolson deposits. Since no known impermeable zone of regional extent separates these aquifers, the Rio Grande alluvium and the Hueco Bolson are considered to be, at least in part, hydrologically connected in the City Artesian and Lower Valley areas (Alvared and Buckner, 1980). The Mesa area primarily consists of Hueco Bolson deposits. Historic withdrawals of groundwater since 1906 for public water supply and irrigation have caused major declines in the water levels. The average water level decline in the Hueco Bolson from 1903 to 1980 is approximately 53 feet (White, 1987).

Locally, recharge to the aquifer occurs due to mountain front infiltration of precipitation from the surface and from the injection of treated sewage into the aquifer from the Hueco Bolson Recharge Project (White and Sladek, 1990). Numerous injection wells were constructed northeast of El Paso and water from the Fred Hervey Water Treatment Plant has been injected into the aquifer by El Paso Water Utilities (EPWU) since the mid-1980s. Since 1991, EPWU has been selling water to El Paso Electric Company for use as cooling water at the Newman Plant, thus less water has been injected into the aquifer (Sperka, 1993).

Based on available information, regional groundwater flow direction in the McCombs Landfill area is to the south-southeast. Groundwater movement in the area is generally less than 1.0 feet per day (White, 1987). EPWU groundwater data indicate that the static groundwater elevation in the area is between 3,670 and 3,675 feet MSL or approximately 370 to 390 feet below ground surface (EPWU, 1993).

Groundwater conditions at the site were determined using data from three groundwater monitoring wells constructed in 2003 around the landfill as part of the approved Subtitle D groundwater monitoring system. Water levels data from December 6, 2010

indicates ground water beneath the site occur approximately 390 to 398 feet below land surface, with corresponding elevations of 3,677 to 3,686 feet AMSI. Based on groundwater level measurements at the site, groundwater flow direction is S70° East or to the east-southeast.

Parkhill, Smith & Copper (PSC) completing an additional hydrogeologic evaluation for the Landfill that included the installation of two additional monitoring wells PZ-4 and PZ-5. Data collected from August 2011 through July 2012 indicate groundwater flow direction is predominately to the east/southeast, likely influenced by the drawdown from the Cemex well located near the southeast corner of the landfill and just north of Stan Roberts Road. The PSC report also notes a northwest component of groundwater flow in the southwest portion of the site.

The site-specific groundwater flow direction correlates with regional groundwater flow direction within the Hueco Bolson aquifer.

2.7.2 Surface Water Conditions

Surface water conditions for the development of the site was designed to be consistent with 30 TAC 330.61(k). The surface water drainage report and design is included in Section 3.3 – Facility Surface Water Drainage Report.

The Landfill is located in the city limits of El Paso and encompasses a total of ***347***~~327~~ acres. The surrounding areas are generally unpopulated and are predominantly undeveloped, agricultural or industrial.

Currently, stormwater on site is directed away from active portions of the landfill by ditches designed for the 25-year storm event. The ditches direct water to the three onsite stormwater retention ponds. These ponds are designed to hold the 100-year storm event as well as contingency storage for sediment. Stormwater runoff is collected in a v-ditch around the perimeter of the landfill units and is directed into an existing stormwater pond on the southeastern corner. Runoff from north of the existing landfill is currently captured within the mined pit area. Some of the runoff in the northwest corner continues to the site of existing Retention Pond A. Runoff generated to the east is captured in the mined pit area. Runoff generated in the existing landfill areas is conveyed into existing Retention Pond D, west of the existing fee house, and existing Retention Pond E, in the southeastern corner of the developed landfill area. These exiting stormwater patterns are shown on Drawing P3-4, Existing Drainage Conditions, in Appendix 3C.

Four ponds will exist in the final cover condition. The final contours include four ponds to break up drainage areas (the existing Retention Ponds A and E, and Ponds B and C), and in effect reduce sheet flow and minimize erosion. Existing Pond D is no longer needed as that area is filled to grade and flow is conveyed in a v-ditch to Pond E. Perimeter ditches will be constructed as the landfill final contours are approached. These ditches will direct water to the retention ponds where they will retain the 100-year event and sediment. The landfill will provide care and management, both during construction and long term, of soil erosion and control of sediment due to surface water.

The care and management of soil erosion and sedimentation is outlined in Part III – Erosion and Sedimentation Control Plan. The facility will prevent discharge of pollutants to waters of the state. There are no waters of the United States or Corps of Engineers' jurisdictional waters of the state on site, therefore, no Section 404 permit is required. The Landfill submitted a notice of intent (NOI) to comply with the Texas Pollutant Discharge Elimination System (TPDES) Stormwater Permit relating to stormwater discharge and received Permit No. TX05L795 from the TCEQ on October 28, 2011. A copy of this permit is included in Appendix 2D – TPDES Multi-Sector General Permit.

2.7.1 Groundwater Conditions

Consistent with §330.61(k)(1), a discussion of groundwater conditions at and near the facility was prepared. Data pertaining to the hydrogeology of the area and groundwater beneath the Landfill are provided in the reports *Site Characterization and Monitoring Plan, McCombs Municipal Landfill, El Paso, Texas* (SHB-AGRA, 1993) ***included in Appendix 3K, Attachment 1*** and *Groundwater Monitoring System Installation, City of El Paso McCombs Landfill-Permit No. MSW-729A* (Raba-Kistner, 2003) ***included in Appendix 3L, Attachment 1.***

The regional groundwater system in the area primarily consists of the Hueco Bolson aquifers. The Hueco Bolson is divided into the City Artesian area, the Mesa area and the Lower Valley (Leggart, 1962). The Mesa area extends north of the City Artesian area into New Mexico and east to the Hueco Mountains. The Landfill is located within the Mesa area.

Two aquifers occur in these areas: an upper aquifer in the Rio Grande alluvium and a lower aquifer in the Hueco Bolson deposits. Since no known impermeable zone of regional extent separates these aquifers, the Rio Grande alluvium and the Hueco Bolson are considered to be, at least in part, hydrologically connected in the City Artesian and Lower Valley areas (Alvared and Buckner, 1980). The Mesa area primarily consists of Hueco Bolson deposits. Historic withdrawals of groundwater since 1906 for public water supply and irrigation have caused major declines in the water levels. The average water level decline in the Hueco Bolson from 1903 to 1980 is approximately 53 feet (White, 1987).

Locally, recharge to the aquifer occurs due to mountain front infiltration of precipitation from the surface and from the injection of treated sewage into the aquifer from the Hueco Bolson Recharge Project (White and Sladek, 1990). Numerous injection wells were constructed northeast of El Paso and water from the Fred Hervey Water Treatment Plant has been injected into the aquifer by El Paso Water Utilities (EPWU) since the mid-1980s. Since 1991, EPWU has been selling water to El Paso Electric Company for use as cooling water at the Newman Plant, thus less water has been injected into the aquifer (Sperka, 1993).

Based on available information, regional groundwater flow direction in the McCombs Landfill area is to the south-southeast. Groundwater movement in the area is generally less than 1.0 feet per day (White, 1987). EPWU groundwater data indicate that the static groundwater elevation in the area is between 3,670 and 3,675 feet MSL or approximately 370 to 390 feet below ground surface (EPWU, 1993).

Groundwater conditions at the site were determined using data from three groundwater monitoring wells constructed in 2003 around the landfill as part of the approved Subtitle D groundwater monitoring system. Water levels data from December 6, 2010

indicates ground water beneath the site occur approximately 390 to 398 feet below land surface, with corresponding elevations of 3,677 to 3,686 feet AMSI. Based on groundwater level measurements at the site, groundwater flow direction is S70° East or to the east-southeast. The site-specific groundwater flow direction correlates with regional groundwater flow direction within the Hueco Bolson aquifer.

2.7.2 Surface Water Conditions

Surface water conditions for the development of the site was designed to be consistent with 30 TAC 330.61(k). The surface water drainage report and design is included in Section 3.3 – Facility Surface Water Drainage Report.

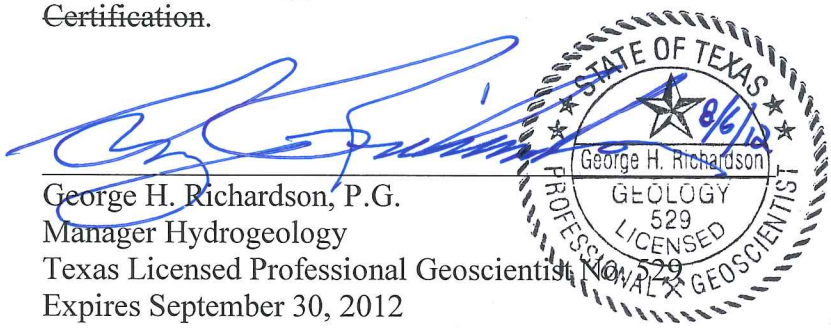
The Landfill is located in the city limits of El Paso and encompasses a total of 327 acres. The surrounding areas are generally unpopulated and are predominantly undeveloped, agricultural or industrial.

Currently, stormwater on site is directed away from active portions of the landfill by ditches designed for the 25-year storm event. The ditches direct water to the three onsite stormwater retention ponds. These ponds are designed to hold the 100-year storm event as well as contingency storage for sediment. Stormwater runoff is collected in a v-ditch around the perimeter of the landfill units and is directed into an existing stormwater pond on the southeastern corner. Runoff from north of the existing landfill is currently captured within the mined pit area. Some of the runoff in the northwest corner continues to the site of existing Retention Pond A. Runoff generated to the east is captured in the mined pit area. Runoff generated in the existing landfill areas is conveyed into existing Retention Pond D, west of the existing fee house, and existing Retention Pond E, in the southeastern corner of the developed landfill area. These exiting stormwater patterns are shown on Drawing P3-4, Existing Drainage Conditions, in Appendix 3C.

Four ponds will exist in the final cover condition. The final contours include four ponds to break up drainage areas (the existing Retention Ponds A and E, and Ponds B and C), and in effect reduce sheet flow and minimize erosion. Existing Pond D is no longer needed as that area is filled to grade and flow is conveyed in a v-ditch to Pond E. Perimeter ditches will be constructed as the landfill final contours are approached. These ditches will direct water to the retention ponds where they will retain the 100-year event and sediment. The landfill will provide care and management, both during construction and long term, of soil erosion and control of sediment due to surface water.

The care and management of soil erosion and sedimentation is outlined in Part III – Erosion and Sedimentation Control Plan. The facility will prevent discharge of pollutants to waters of the state. There are no waters of the United States or Corps of Engineers' jurisdictional waters of the state on site, therefore, no Section 404 permit is required. The Landfill submitted a notice of intent (NOI) to comply with the ***Texas Pollutant Discharge Elimination System (TPDES) Stormwater*** ~~NPDES General~~ Permit relating to stormwater discharge and received Permit No. ***TX05L795***~~TXR05E214~~ from the ***TCEQ on October 28, 2011***~~United States~~

~~Environmental Protection Agency (U.S. EPA) in June of 1998~~. A copy of this permit is included in Appendix 2D – ***TPDES Multi-Sector General Permit*** ~~NPDES Certification~~.



George H. Richardson, P.G.
Manager Hydrogeology
Texas Licensed Professional Geoscientist No. 529
Expires September 30, 2012

A floodplain restrictions and wetlands restrictions report was completed in June of 1994 by SHB AGRA Earth and Environmental (SHB) and is provided for reference in Appendix 3K, Attachment 4. Information from that report has been included in this statement to meet the requirements of 30 TAC §330.61(m).

2.9.1 Floodplains

According to 40 CFR §258.11**,** 30 TAC §330.307 and §330.547, "owners or operators of new MSWLF units, existing MSWLF units, and lateral expansions located in 100-year floodplains must demonstrate that the unit will not restrict the flow of the 100-year flood, reduce the temporary water storage capacity of the floodplain, or results in washout of solid waste so as to pose a hazard to human health and the environment."

As shown in the Federal Emergency Management Agency (FEMA) Flood Insurance Rate Map (FIRM) provided in Appendix 2E – Floodplains and Wetlands Documentation, a portion of the landfill is located within the 100-year floodplain. No waste disposal activities will occur in the section of the property lying within the 100-year floodplain. Instead, existing Retention Pond A has been designed to cover the area affected by the 100-year floodplain. Refer to Section 3.3 – Facility Surface Water Drainage Report for further details concerning the effects of the 100-year floodplain and the design of the stormwater detention ponds.

2.9.2 Wetlands

According to 30 TAC §330.553, new MSW landfill units, lateral expansions, and material recovery operations from a landfill shall not be located in wetlands, unless the owner or operator makes specific demonstrations to show that the landfill will not cause environmental harm.

Based on a 1982 map prepared by T.E. Dohl, the Landfill is not located in area designated as a wetland. This map is included in ***Appendix*** ~~Attachment~~ 2E – Floodplains and Wetlands Documentation.

Section 2.9
FLOODPLAINS AND WETLANDS STATEMENT
30 TAC §330.61(m)

A floodplain restrictions and wetlands restrictions report was completed in June of 1994 by SHB AGRA Earth and Environmental (SHB) ***and is provided for reference in Appendix 3K, Attachment 4***. Information from that report has been included in this statement to meet the requirements of 30 TAC §330.61(m).

2.9.1 Floodplains

According to 40 CFR §258.11**,** ~~and~~ 30 TAC §330.307 ***and §330.547***, "owners or operators of new MSWLF units, existing MSWLF units, and lateral expansions located in 100-year floodplains must demonstrate that the unit will not restrict the flow of the 100-year flood, reduce the temporary water storage capacity of the floodplain, or results in washout of solid waste so as to pose a hazard to human health and the environment."

As shown in the Federal Emergency Management Agency (FEMA) Flood Insurance Rate Map (FIRM) provided in Appendix 2E – Floodplains and Wetlands Documentation, a portion of the landfill is located within the 100-year floodplain. No waste disposal activities will occur in the section of the property lying within the 100-year floodplain. Instead, existing Retention Pond A has been designed to cover the area affected by the 100-year floodplain. Refer to Section 3.3 – Facility Surface Water Drainage Report for further details concerning the effects of the 100-year floodplain and the design of the stormwater detention ponds.

2.9.2 Wetlands

According to 30 TAC §330.553, new MSW landfill units, lateral expansions, and material recovery operations from a landfill shall not be located in wetlands, unless the owner or operator makes specific demonstrations to show that the landfill will not cause environmental harm.

Based on a 1982 map prepared by T.E. Dohl, the Landfill is not located in area designated as a wetland. This map is included in Attachment 2E – Floodplains and Wetlands Documentation.

Section 2.10
ENDANGERED SPECIES STATEMENT
30 TAC §330.61(n)

To meet the requirements of 30 TAC §330.61(n) and 30 TAC §330.551, a letter dated August 13, 1982 from the United States Fish and Wildlife Service (USFWS) has been included in Appendix 2F – Endangered Species Documentation. This letter was previously included in both the 1984 and 2002 permit amendment application submittals. Additionally, current correspondence between the Texas Parks and Wildlife Department ***(TPWD)*** and the U.S. Fish and Wildlife Service is also provided in Appendix 2F.

According to the ***1982*** USFWS letter, the American Peregrine Falcon may use the project site as a feeding area or pass through the area during migration. According to the information provided on the USFWS website, the American Peregrine Falcon was delisted from the federal endangered species list on August 25, 1999. However, the American Peregrine Falcon remains a State of Texas protected species. A copy of the USFWS species profile is also provided in Appendix 2F – Endangered Species Documentation.

As indicated in the USFWS letter, it is unlikely that the Landfill will have any effect on this species. However, if the American Peregrine Falcon were to be observed within the permitted landfill area, the employees will be instructed to follow the steps listed below:

1. Avoid contact with the bird;
2. Temporarily halt or move site operations to an area away from the bird's location to prevent disrupting the bird's activities while feeding or passing by the site;
3. Wait until the bird abandons the site on its own will; and
4. Resume normal site operations once the bird has taken flight.

In addition, Landfill personnel will be trained regarding the bird's physical characteristics and appearance in order to be able to identify it at once and with certainty during operations. This training will prevent unnecessary and unwarranted disruptions of site activities due to the presence of birds that may look similar to the American Peregrine Falcon.

According to the 2012 TPWD response letter, the following species have been listed as threatened or endangered under the Endangered Species Act (ESA) and have the potential to occur in El Paso County:

- ***Least Tern – Listed 08/28/1985***
- ***Northern Aplomado Falcon – Listed 02/25/1986***
- ***Mexican Spotted Owl – Listed 03/16/1993***
- ***Southwestern Willow Flycatcher – Listed 02/27/1995***

The following are state-listed threatened species that could potentially occur in the area:

- ***Texas Horned Lizard***
- ***Mountain Short-Horned Lizard***

The following are state-listed species of concern that could potentially occur in the area:

- ***Western Burrowing Owl***
- ***Desert Night-Blooming Cereus***

Further information regarding these species, their suitable habitats, and avoidance procedures are included in Appendix 2F.

Section 2.10
ENDANGERED SPECIES STATEMENT
30 TAC §330.61(n)

To meet the requirements of 30 TAC §330.61(n) and 30 TAC §330.551, a letter dated August 13, 1982 from the United States Fish and Wildlife Service (USFWS) has been included in Appendix 2F – Endangered Species Documentation. This letter was previously included in both the 1984 and 2002 permit amendment application submittals. Additionally, current correspondence between the Texas Parks and Wildlife Department and the U.S. Fish and Wildlife Service is also provided in Appendix 2F.

According to the USFWS letter, the American Peregrine Falcon may use the project site as a feeding area or pass through the area during migration. According to the information provided on the USFWS website, the American Peregrine Falcon was delisted from the federal endangered species list on August 25, 1999. However, the American Peregrine Falcon remains a State of Texas protected species. A copy of the USFWS species profile is also provided in Appendix 2F – Endangered Species Documentation.

As indicated in the USFWS letter, it is unlikely that the Landfill will have any effect on this species. However, if the American Peregrine Falcon were to be observed within the permitted landfill area, the employees will be instructed to follow the steps listed below:

1. Avoid contact with the bird;
2. Temporarily halt or move site operations to an area away from the bird's location to prevent disrupting the bird's activities while feeding or passing by the site;
3. Wait until the bird abandons the site on its own will; and
4. Resume normal site operations once the bird has taken flight.

In addition, Landfill personnel will be trained regarding the bird's physical characteristics and appearance in order to be able to identify it at once and with certainty during operations. This training will prevent unnecessary and unwarranted disruptions of site activities due to the presence of birds that may look similar to the American Peregrine Falcon.

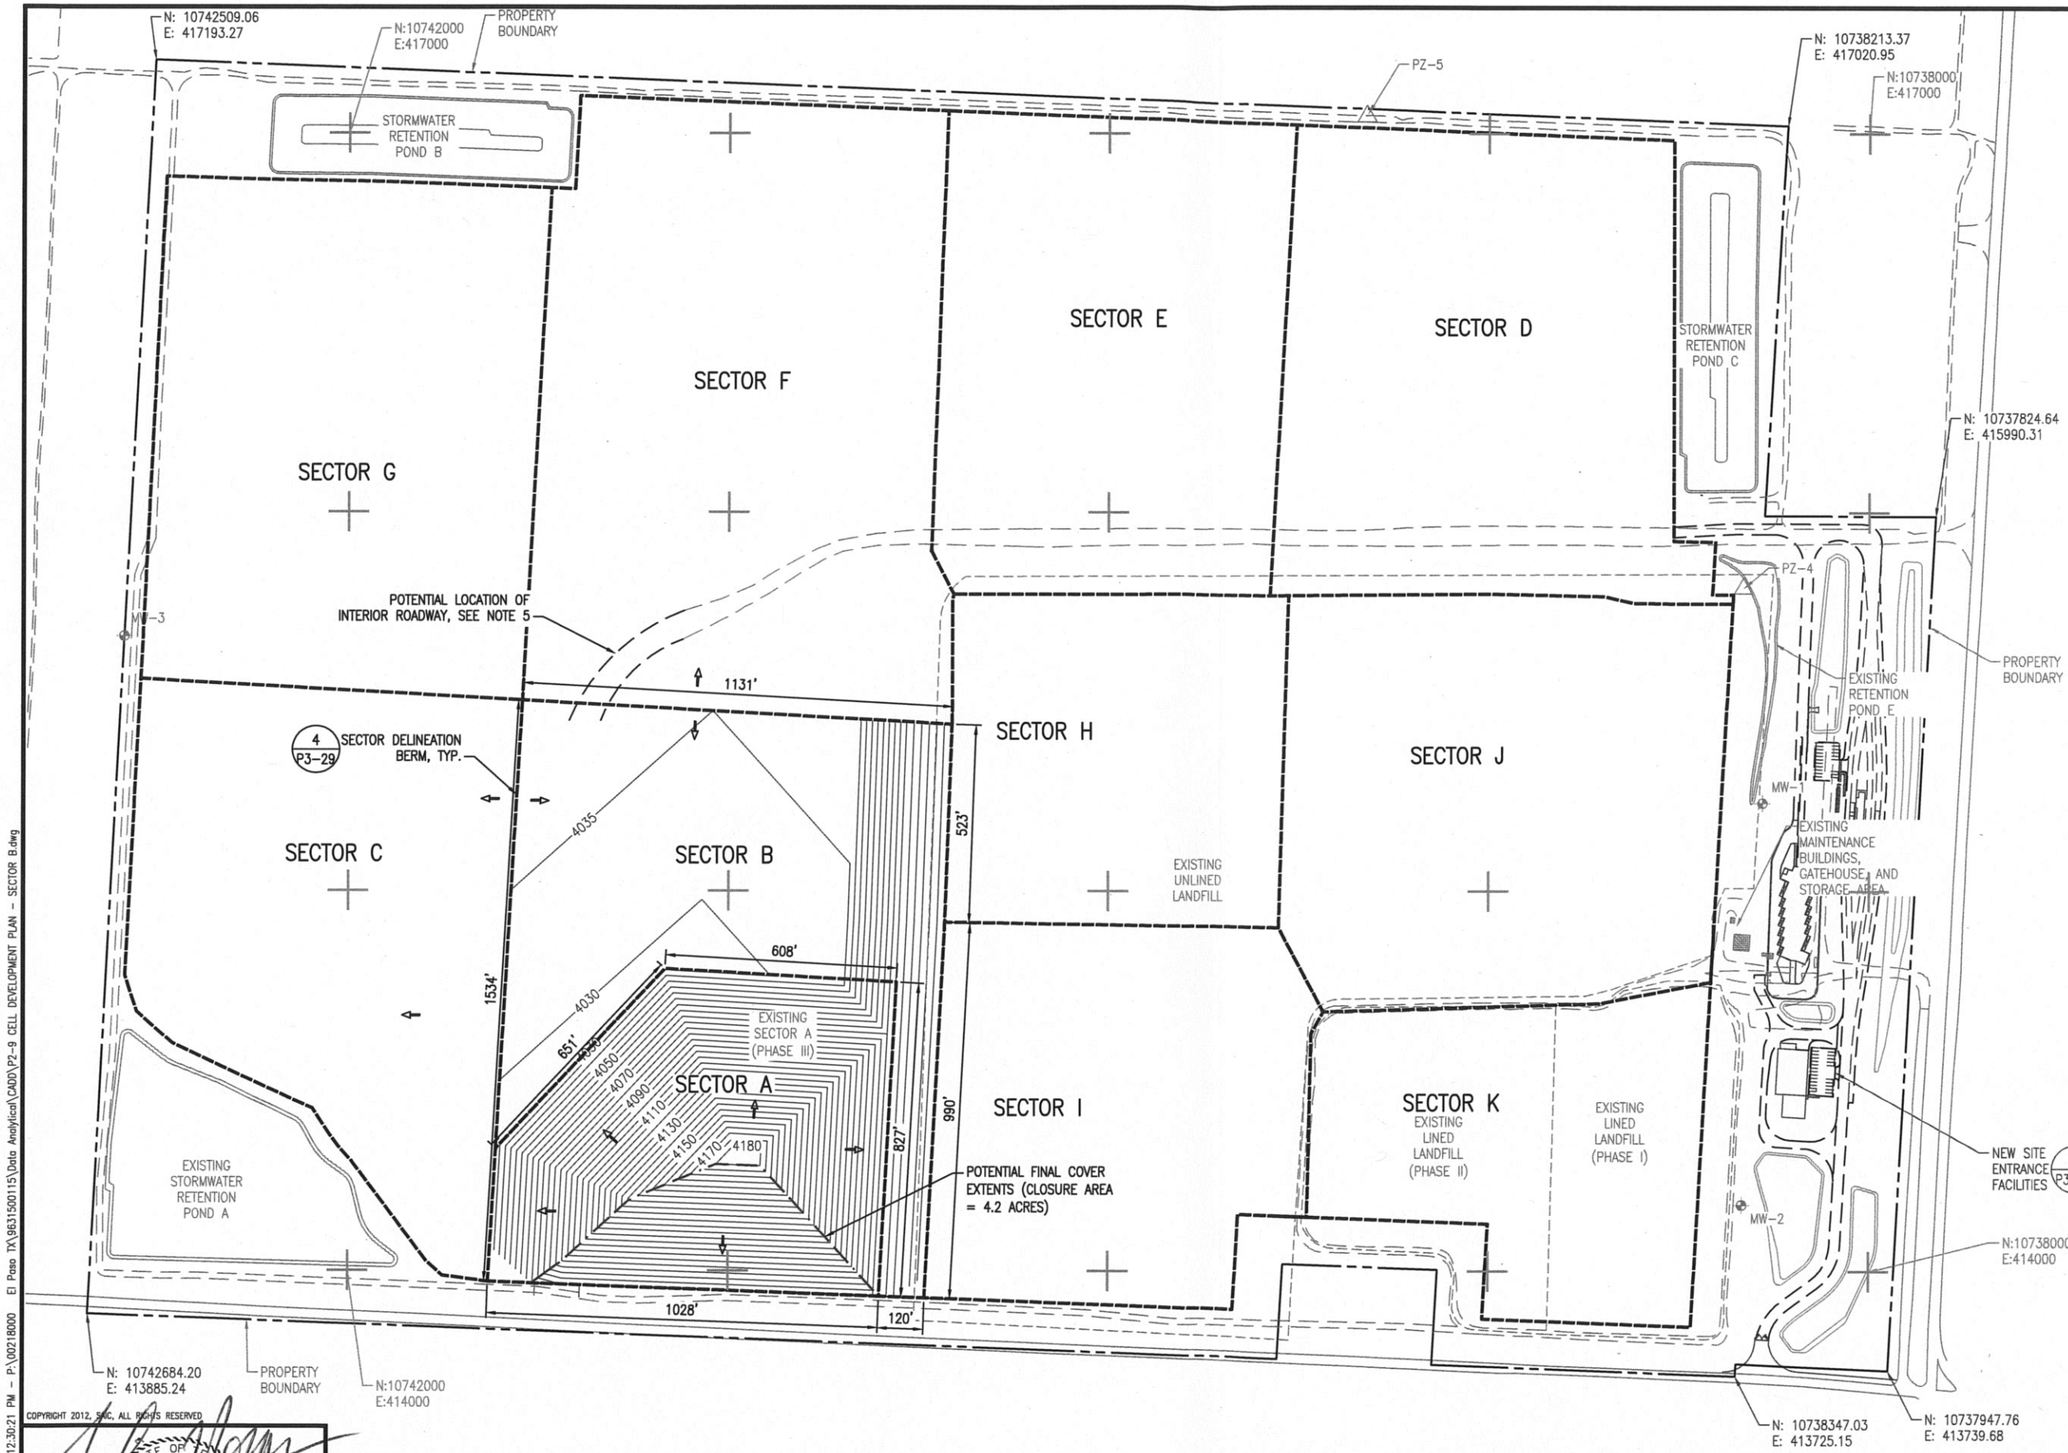
SITE FACILITY LAYOUT

PROJECT NUMBER: 9631500115
SHT. 14 OF: 78
DRAWING NUMBER: P2–8



NOTES

1. CONTOURS SHOWN REPRESENT DESIGN PHASING CONTOURS FOR SECTOR B DEVELOPMENT AND SUBSEQUENT SECTOR A INTERMEDIATE/FINAL COVER.
2. CONTOUR INTERVAL IS FIVE FEET. ELEVATIONS ARE CITY OF EL PASO VERTICAL DATUM.
3. SECTOR B CONTOURS WILL BE TIED INTO EXISTING CONTOURS WITH A MAXIMUM 3:1 SLOPE.
4. SECTORS A THROUGH J WILL BE UTILIZED FOR MUNICIPAL SOLID WASTE PLACEMENT. SECTOR K WILL BE UTILIZED FOR CONTINUED MSW/ASBESTOS PLACEMENT DURING OTHER FILLING OPERATIONS.
5. ACTUAL LOCATION OF INTERIOR FACILITY ACCESS ROAD MAY VARY DEPENDENT ON SITE DEVELOPMENT AND OPERATOR DISCRETION.

NOTES

1. CONTOURS SHOWN REPRESENT DESIGN PHASING CONTOURS FOR SECTOR K DEVELOPMENT AND SUBSEQUENT SECTOR J INTERMEDIATE/FINAL COVER.
2. CONTOUR INTERVAL IS FIVE FEET. ELEVATIONS ARE CITY OF EL PASO VERTICAL DATUM.
3. SECTOR K CONTOURS WILL BE TIED INTO EXISTING CONTOURS WITH A MAXIMUM 3:1 SLOPE.
4. SECTOR A THROUGH J WILL BE UTILIZED FOR MUNICIPAL SOLID WASTE PLACEMENT. SECTOR K WILL BE UTILIZED FOR CONTINUED MSW/ASBESTOS PLACEMENT DURING OTHER FILLING OPERATIONS.
5. CONTOURS IN SECTOR K WILL VARY WITH CONTINUED MSW/ASBESTOS FILL.
6. ACTUAL LOCATION OF INTERIOR FACILITY ACCESS ROAD MAY VARY DEPENDENT ON SITE DEVELOPMENT AND OPERATOR DISCRETION.

2B.1 Introduction

The following land use analysis was prepared to evaluate the area surrounding the Landfill property. This study examines the zoning within two miles of the property, the character of the surrounding land within one mile of the property, growth trends within five miles of the property, and the proximity of residences, commercial establishments and other places of interest within one mile of the property. The results are summarized in the following sections.

2B.2 Zoning

The Landfill is located within the City limits approximately 10 miles northwest of downtown, and lies within 500 feet of the Texas-New Mexico border as shown in Drawing P2-24 – Zoning Map. The City and the adjacent Doña Ana County, New Mexico provide zoning ordinances that control the land use within the area.

In Texas, the land surrounding the Landfill is predominately zoned for light or heavy industrial use or as a ranch or farm district. In New Mexico, the surrounding land is zoned as a Performance District (PD) in Doña Ana County. According to the Doña Ana County Land Use Regulations and Zoning Ordinance, the purpose of zoning a region as a PD is to allow flexibility for land use activities in the rural areas of the County by acting as a mixed use zone.

2B.3 Character of Surrounding Land

The land surrounding the Landfill is predominately owned by the City within the State of Texas, and is undeveloped or for rural residential use within the State of New Mexico, as shown in Drawing P2-21 through Drawing P2-23. The following Table 2.4B-1 provides a detailed breakdown of the land use within a one-mile radius of the Landfill.

Table 2.4B-1
Land Use Within One Mile of McCombs Landfill

Land Use	Area (Acres)	Area (Percent of Total)
City of El Paso	2,133.01	51.57%
Undeveloped	973.10	23.53%
Industrial	617.02	14.92%
Residential	233.78	5.65%
No Classified Activity	100.03	2.42%
Right-of-Way/Utility	58.89	1.42%
Mixed Use	14.55	0.35%
Commercial	5.86	0.14%
Total	4,136.24	100.00%

As shown in Table 2.4B-1, 51.57 percent of the land within a one-mile radius of the Landfill is owned by the City of El Paso and 23.53 percent of land is undeveloped. Residential housing accounts for approximately 5.65 percent of the land within a one-mile radius of the Landfill.

No schools, licensed day-care facilities, churches, hospitals, cemeteries, or lakes were identified through visual survey or parcel records within one mile of the Landfill. One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.

2B.4 Growth Trends

Visual comparison of the two sets of Census tracts revealed that three of the 2000 Census have been divided for the 2010 Census. To make a valid comparison between each 2000 tract and the corresponding area of the 2010 tracts, Table 2.4B-2 was created. Table 2.4B-2 shows the tracts and population from the 2000 and 2010 Censuses. Some 2000 Census tracts in the five mile radius surrounding the Landfill were divided for the 2010 Census. In these cases, population totals for the 2010 tracts were summed to reflect an area equivalent to the 2000 Census tract.

Table 2.4B-2
Growth Trends Within Five Miles of McCombs Landfill

2000 Census		2010 Census		Total 2010 Population	Percent Change
Tract	Population	Tract	Population		
1.06	5,266	1.06	6,081	6,081	15.47
1.07	6,033	1.07	5,087	5,087	-3.75
1.08	2,844	1.08	2,505	2,505	-13.14
2.03	7,122	2.07	4,761	8,190	14.99
		2.08	3,429		
9.00	8,705	9.01	3,167	13,108	50.58
		9.02	9,941		
18.02	5,807	18.02	6,354	6,354	9.42
18.04	6,117	18.04	6,965	6,965	13.86
101.01	1,384	101.01	3,673	3,673	165.39
102.06	7,795	102.1	5,902	14,445	85.31
		102.11	2,930		
		102.12	5,613		
102.07	2,266	102.07	4,803	4,803	111.96

As can be seen from Table 2.4B-2, several tracts had significant growth from 2000 to 2010. These high-growth tracts are located southeast of the landfill and are mostly owned by the City of El Paso or zoned for mixed use as shown on the Land Use Map included as Drawing P2-23. The high growth for these tracts can be attributed to the construction of two neighborhoods approximately 2.5 to 3 miles away, respectively.

According to the United States Census Bureau, El Paso County experienced a growth rate of approximately 10.5 percent between 2000 and 2009[1] and Dona Ana County experienced a growth rate of approximately 18.2 percent between 2000 and 2009. A majority of the population growth rates summarized in Table 2.4B-2 follow these trends.

2B.5 Proximity to Residences, Commercial Establishments and Other Uses

Based on the visual survey conducted on November 10th, 2010, and from parcel data received from Doña Ana County, New Mexico, there are approximately 185 single family residences and mobile homes within a one-mile radius of the Landfill. The residence closest to filling activities is estimated to be 1,500 feet from the property boundary, and 1,550 feet from the waste limit.

SAIC identified 8 parcels of mixed use/commercial establishments within one mile of the facility (refer to Drawing P2-3 in Appendix 2B). The area immediately to the east of the Landfill is a quarry operated by Cemex, to the south approximately one mile is El Paso Natural Gas Company (private), and immediately to the west is an

[1] Most recent data available from the United States Census Bureau is for 2009.

undeveloped area owned by El Paso Electric (private). To the northeast of the Landfill, within New Mexico (0.25 to 1-mile away), are 5 identified small businesses within the residential neighborhood.

SAIC did not identify any schools, licensed day care centers, churches, hospitals, cemeteries, lakes, streams, archaeologically significant sites, historic sites, or locations of exceptional aesthetic quality within one-mile of the Landfill based on the visual survey and parcel records. One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.

2B.6 Conclusions

As can be seen from Table 2.4B-1, approximately 90 percent of the land surrounding the Landfill is either owned by the City, undeveloped or used for industrial purposes. Less than 6 percent of the land within one mile is used for residential use.

Most of the area surrounding the landfill experienced growth similar to the El Paso County and Dona Ana County growth rates. Some areas experienced higher population growth rates due to the construction of neighborhoods within 3 miles of the Landfill. However, it is unlikely that these same growth rates will continue in the future.

SAIC®

2B.1 Introduction

The following land use analysis was prepared to evaluate the area surrounding the Landfill property. This study examines the zoning within two miles of the property, the character of the surrounding land within one mile of the property, growth trends within five miles of the property, and the proximity of residences***, commercial establishments*** and other places of interest within one mile of the property. The results are summarized in the following sections.

2B.2 Zoning

The Landfill is located within the City limits approximately 10 miles northwest of downtown, and lies within 500 feet of the Texas-New Mexico border as shown in Drawing P2-24 – Zoning Map. The City and the adjacent Doña Ana County, New Mexico provide zoning ordinances that control the land use within the area.

In Texas, the land surrounding the Landfill is predominately zoned for light or heavy industrial use or as a ranch or farm district. In New Mexico, the surrounding land is zoned as a Performance District (PD) in Doña Ana County. According to the Doña Ana County Land Use Regulations and Zoning Ordinance, the purpose of zoning a region as a PD is to allow flexibility for land use activities in the rural areas of the County by acting as a mixed use zone.

2B.3 Character of Surrounding Land

The land surrounding the Landfill is predominately owned by the City within the State of Texas, and is undeveloped or for rural residential use within the State of New Mexico, as shown in Drawing P2-21 through Drawing P2-23. The following Table 2.4B-1 provides a detailed breakdown of the land use within a one-mile radius of the Landfill.

Table 2.4B-1
Land Use Within One Mile of McCombs Landfill

Land Use	Area (Acres)	Area (Percent of Total)
City of El Paso	2,133.01	51.57%
Undeveloped	973.10	23.53%
Industrial	617.02	14.92%
Residential	233.78	5.65%
No Classified Activity	100.03	2.42%
Right-of-Way/Utility	58.89	1.42%
Mixed Use	14.55	0.35%
Commercial	5.86	0.14%
Total	4,136.24	100.00%

As shown in Table 2.4B-1, 51.57 percent of the land within a one-mile radius of the Landfill is owned by the City of El Paso and 23.53 percent of land is undeveloped. Residential housing accounts for approximately 5.65 percent of the land within a one-mile radius of the Landfill.

No schools, licensed day-care facilities, churches, hospitals, cemeteries, or lakes were identified through visual survey or parcel records within one mile of the Landfill. One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.

2B.4 Growth Trends

Visual comparison of the two sets of Census tracts revealed that three of the 2000 Census have been divided for the 2010 Census. To make a valid comparison between each 2000 tract and the corresponding area of the 2010 tracts, Table 2.4B-2 was created. Table 2.4B-2 shows the tracts and population from the 2000 and 2010 Censuses. Some 2000 Census tracts in the five mile radius surrounding the Landfill were divided for the 2010 Census. In these cases, population totals for the 2010 tracts were summed to reflect an area equivalent to the 2000 Census tract.

Table 2.4B-2
Growth Trends Within Five Miles of McCombs Landfill

2000 Census		2010 Census		Total 2010 Population	Percent Change
Tract	Population	Tract	Population		
1.06	5,266	1.06	6,081	6,081	15.47
1.07	6,033	1.07	5,087	5,087	-3.75
1.08	2,844	1.08	2,505	2,505	-13.14
2.03	7,122	2.07	4,761	8,190	14.99
		2.08	3,429		
9.00	8,705	9.01	3,167	13,108	50.58
		9.02	9,941		
18.02	5,807	18.02	6,354	6,354	9.42
18.04	6,117	18.04	6,965	6,965	13.86
101.01	1,384	101.01	3,673	3,673	165.39
102.06	7,795	102.1	5,902	14,445	85.31
		102.11	2,930		
		102.12	5,613		
102.07	2,266	102.07	4,803	4,803	111.96

As can be seen from Table 2.4B-2, several tracts had significant growth from 2000 to 2010. These high-growth tracts are located southeast of the landfill and are mostly owned by the City of El Paso or zoned for mixed use as shown on the Land Use Map included as Drawing P2-23. The high growth for these tracts can be attributed to the construction of two neighborhoods approximately 2.5 to 3 miles away, respectively.

According to the United States Census Bureau, El Paso County experienced a growth rate of approximately 10.5 percent between 2000 and 2009[1] and Dona Ana County experienced a growth rate of approximately 18.2 percent between 2000 and 2009. A majority of the population growth rates summarized in Table 2.4B-2 follow these trends.

2B.5 Proximity to Residences, *Commercial Establishments* and Other Uses

Based on the visual survey conducted on November 10th, 2010, and from parcel data received from Doña Ana County, New Mexico, there are approximately 185 single family residences and mobile homes within a one-mile radius of the Landfill. The residence closest to filling activities is estimated to be 1,500 feet from the property boundary, and 1,550 feet from the waste limit.

SAIC identified 8 parcels of mixed use/commercial establishments within one mile of the facility (refer to Drawing P2-3 in Appendix 2B). The area immediately to the east of the Landfill is a quarry operated by Cemex, to the south approximately one mile is El Paso Natural Gas Company (private), and immediately to the west is an

[1] Most recent data available from the United States Census Bureau is for 2009.

undeveloped area owned by El Paso Electric (private). To the northeast of the Landfill, within New Mexico (0.25 to 1-mile away), are 5 identified small businesses within the residential neighborhood.

SAIC did not identify any schools, licensed day care centers, churches, hospitals, cemeteries, lakes, streams, archaeologically significant sites, historic sites, or locations of exceptional aesthetic quality within one-mile of the Landfill based on the visual survey and parcel records. One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.

2B.6 Conclusions

As can be seen from Table 2.4B-1, approximately 90 percent of the land surrounding the Landfill is either owned by the City, undeveloped or used for industrial purposes. Less than 6 percent of the land within one mile is used for residential use.

Most of the area surrounding the landfill experienced growth similar to the El Paso County and Dona Ana County growth rates. Some areas experienced higher population growth rates due to the construction of neighborhoods within 3 miles of the Landfill. However, it is unlikely that these same growth rates will continue in the future.

2B.1 Introduction

The following land use analysis was prepared to evaluate the area surrounding the Landfill property. This study examines the zoning within two miles of the property, the character of the surrounding land within one mile of the property, growth trends within five miles of the property, and the proximity of residences and other places of interest within one mile of the property. The results are summarized in the following sections.

2B.2 Zoning

The Landfill is located within the City limits approximately 10 miles northwest of downtown, and lies within 500 feet of the Texas-New Mexico border as shown in Drawing P2-24 – Zoning Map. The City and the adjacent Doña Ana County, New Mexico provide zoning ordinances that control the land use within the area.

In Texas, the land surrounding the Landfill is predominately zoned for light or heavy industrial use or as a ranch or farm district. In New Mexico, the surrounding land is zoned as a Performance District (PD) in Doña Ana County. According to the Doña Ana County Land Use Regulations and Zoning Ordinance, the purpose of zoning a region as a PD is to allow flexibility for land use activities in the rural areas of the County by acting as a mixed use zone.

2B.3 Character of Surrounding Land

The land surrounding the Landfill is predominately owned by the City within the State of Texas, and is undeveloped or for rural residential use within the State of New Mexico, as shown in Drawing P2-21 through Drawing P2-23. The following Table 2.4B-1 provides a detailed breakdown of the land use within a one-mile radius of the Landfill.

Table 2.4B-1
Land Use Within One Mile of McCombs Landfill

Land Use	Area (Acres)	Area (Percent of Total)
City of El Paso	2,133.01	51.57%
Undeveloped	973.10	23.53%
Industrial	617.02	14.92%
Residential	233.78	5.65%
No Classified Activity	100.03	2.42%
Right-of-Way/Utility	58.89	1.42%
Mixed Use	14.55	0.35%
Commercial	5.86	0.14%
Total	4,136.24	100.00%

As shown in Table 2.4B-1, 51.57 percent of the land within a one-mile radius of the Landfill is owned by the City of El Paso and 23.53 percent of land is undeveloped. Residential housing accounts for approximately 5.65 percent of the land within a one-mile radius of the Landfill.

No schools, licensed day-care facilities, churches, ***hospitals,*** ~~or~~ cemeteries***, or lakes*** were identified through visual survey or parcel records within one mile of the Landfill. ***One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.***

2B.4 Growth Trends

Visual comparison of the two sets of Census tracts revealed that three of the 2000 Census have been divided for the 2010 Census. To make a valid comparison between each 2000 tract and the corresponding area of the 2010 tracts, Table 2.4B-2 was created. Table 2.4B-2 shows the tracts and population from the 2000 and 2010 Censuses. Some 2000 Census tracts in the five mile radius surrounding the Landfill were divided for the 2010 Census. In these cases, population totals for the 2010 tracts were summed to reflect an area equivalent to the 2000 Census tract.

Table 2.4B-2
Growth Trends Within Five Miles of McCombs Landfill

2000 Census		2010 Census		Total 2010 Population	Percent Change
Tract	Population	Tract	Population		
1.06	5,266	1.06	6,081	6,081	15.47
1.07	6,033	1.07	5,087	5,087	-3.75
1.08	2,844	1.08	2,505	2,505	-13.14
2.03	7,122	2.07	4,761	8,190	14.99
		2.08	3,429		
9.00	8,705	9.01	3,167	13,108	50.58
		9.02	9,941		
18.02	5,807	18.02	6,354	6,354	9.42
18.04	6,117	18.04	6,965	6,965	13.86
101.01	1,384	101.01	3,673	3,673	165.39
102.06	7,795	102.1	5,902	14,445	85.31
		102.11	2,930		
		102.12	5,613		
102.07	2,266	102.07	4,803	4,803	111.96

As can be seen from Table 2.4B-2, several tracts had significant growth from 2000 to 2010. These high-growth tracts are located southeast of the landfill and are mostly owned by the City of El Paso or zoned for mixed use as shown on the Land Use Map included as Drawing P2-23. The high growth for these tracts can be attributed to the construction of two neighborhoods approximately 2.5 to 3 miles away, respectively.

According to the United States Census Bureau, El Paso County experienced a growth rate of approximately 10.5 percent between 2000 and 2009[1] and Dona Ana County experienced a growth rate of approximately 18.2 percent between 2000 and 2009. A majority of the population growth rates summarized in Table 2.4B-2 follow these trends.

2B.5 Proximity to Residences and Other Uses

Based on the visual survey conducted on November 10th, 2010, and from parcel data received from Doña Ana County, New Mexico, there are approximately 185 single family residences and mobile homes within a one-mile radius of the Landfill. The residence closest to filling activities is estimated to be 1,500 feet from the property boundary, and 1,550 feet from the waste limit.

SAIC did not identify any schools, ***licensed*** day care centers, ***churches, hospitals, cemeteries, lakes, streams,*** archaeologically significant sites, ***historic sites,*** or locations of exceptional aesthetic quality within one-mile of the Landfill based on the visual survey and parcel records. ***One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for***

[1] Most recent data available from the United States Census Bureau is for 2009.

stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.

2B.6 Conclusions

As can be seen from Table 2.4B-1, approximately 90 percent of the land surrounding the Landfill is either owned by the City, undeveloped or used for industrial purposes. Less than 6 percent of the land within one mile is used for residential use.

Most of the area surrounding the landfill experienced growth similar to the El Paso County and Dona Ana County growth rates. Some areas experienced higher population growth rates due to the construction of neighborhoods within 3 miles of the Landfill. However, it is unlikely that these same growth rates will continue in the future.

Mr. Fredric J. Doran, P.E.
Senior Environmental Engineer
SAIC Energy, Environment, and Infrastructure
1380 Corporate Center Curve, Suite 305
St. Paul, MN 55121

Dear Mr. Doran:

This is in response to your letter of January 11, 2012, about the proposed expansion of the McCombs Municipal Solid Waste Landfill in El Paso, Texas. Based on the information provided, we found no public-use airports within five miles of the site. We have no objection to the proposal from the standpoint of potential wildlife hazards to aircraft.

We have assigned this proposed landfill site File No. 2012-002TX. Please use this number in any future correspondence about this facility. Thank you for coordinating this project with the Federal Aviation Administration.

If you have any questions, please call me at (817) 222-5656.

Sincerely,

Faye Nedderman
Executive Technical Assistant

Subject: **Facility Compliance with Airport Safety**
McCombs Municipal Solid Waste Landfill, El Paso, Texas

Dear Ms. Nedderman:

The McCombs Municipal Solid Waste Landfill (Landfill) located in El Paso, Texas (City) is proposing a vertical expansion of the existing Landfill footprint to provide additional capacity. The Landfill is located in El Paso County within the El Paso city limits and serves the waste needs of the City and the surrounding area. The Landfill is an existing Type 1 MSW disposal facility owned and operated by the City. The Landfill is located at the northeast corner of the intersection of McCombs Road and Stan Roberts Road (FM 2529) in El Paso, Texas. The address of the Landfill is 13660 McCombs Road.

The proposed vertical expansion will increase the height of the Landfill from the currently permitted elevation of 4,125 feet mean sea level (MSL) to 4,305 feet MSL. The existing permitted boundary of the Landfill is currently 327 acres (permitted in 1984), and is not proposed to increase. The primary use for this facility will remain dedicated for disposal of municipal solid waste.

Pursuant to Texas Administrative Code Chapter 330 (30 TAC §330.61 (i)(5) and 30 TAC §330.545 (a)), please verify that the facility is not:

1. Located within 10,000 feet of any airport runway end used by turbojet aircraft;
2. Within 5,000 feet of any airport runway end used by only piston-type aircraft;
3. Within a six mile radius of any small general service airport runway end used by turbojet or piston-type aircraft; or
4. Within a five mile radius of any large general public commercial airport runway end used by turbojet or piston-type aircraft.

Subject: **Transportation Impact Analysis**
McCombs Municipal Solid Waste Landfill, El Paso, Texas

Dear Mr. Fino:

The City of El Paso is anticipating reopening the McCombs Landfill (located on McCombs and Stan Roberts Road) and has prepared a Traffic Impact Analysis (TIA) that was sent to you previously for review, and is included as Attachment 1 for your reference. The Landfill is located at the northeast corner of the intersection of McCombs Road and Stan Roberts Road (FM 2529) in El Paso, Texas. The address of the Landfill is 13660 McCombs Road.

The purpose of this letter is to document correspondence with the Texas Department of Transportation (TxDOT) pursuant to Texas Administrative Code Chapter 330 (30 TAC §330.61 (i)). Please provide a written response to the TIA provided on any traffic or location restrictions that may exist.

If you have any questions or require additional information, please contact me at 651-994-8415 or fredric.j.doran@saic.com.

Sincerely,

SAIC Energy, Environment & Infrastructure, LLC

Traffic Impact Analysis

McCombs Land Fill Facility

Department of Transportation

Jan 12, 2011

STATE OF TEXAS
SERGIO REYES
106645
PROFESSIONAL ENGINEER

4-4-12

Introduction

This Analysis was prepared for the proposed landfill, located immediately east of McCombs between State Line and Stan Roberts. The purpose of the study is to analyze the traffic and transportation impacts of the proposed development on adjacent road network.

Study Area

Figure 1 shows the project site and the surrounding area. McCombs is a two lane undivided roadway which provides north/south travel within the study area. State Line and Stan Roberts are two lane undivided roadways which provides east/west travel.

Figure 1. Study Area

Methodology

For this study, the following milestone years were analyzed:

- Existing (2010)
- Future traffic conditions in the build out year (2011)
- Future traffic conditions 10 year after build out (2021)
- Future traffic conditions end of life of the landfill (2040)

Data Collection

The surrounding roadway network adjacent to the land fill site was analyzed to establish baseline traffic flow.

For this traffic impact study, AM, PM, and ADT volumes are needed to evaluate the roadway capacity analyses. Roadway Tube Counts were taken at various segments in the study area. Figure 2 also shows the existing weekday AM\PM, and 24-hour ADT volumes.

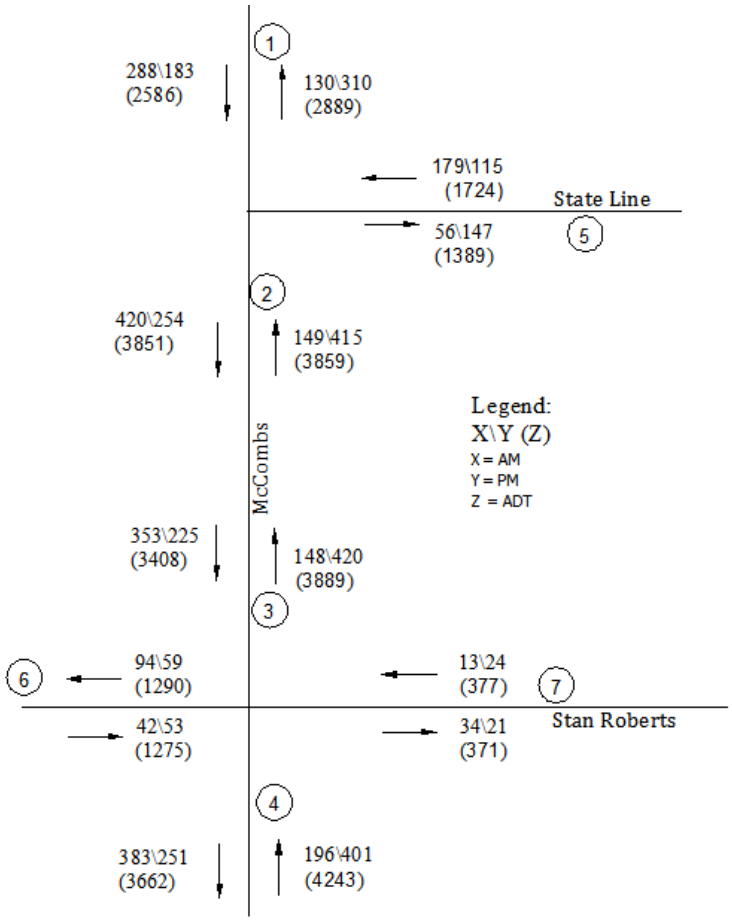

Figure 2: Existing AM\PM and ADT roadway count volumes (2010)

Background Growth
In order to obtain future year background traffic, a growth rate was applied to the existing (2010) traffic volumes to account for ambient growth in traffic. The growth rate was derived from the El Paso MPO model.

Trip Generation and Distribution

Site generated traffic
Site generated traffic was determined based on the information provided by The City of El Paso's Environmental Services department. The trip generation for the Site is shown in Table 1.

	ADT	
	2011	2040
City Trash	80	96
Commercial Trash	100	120
Employees	30	36
Public	100	120

Table 1: Site trip generation

Trip distribution
Distribution of site traffic onto the street system was based on the existing traffic patterns. Multiplying the site generated trips by the percentage distribution provides the projected trip assignments to the road network.

Traffic Operations Analysis

Analysis Methodology

The TransBorder 2035 Metropolitan Transportation Plan (MTP) examines projects based on the volume to capacity ratio (V/C) which was then defined in terms of level of mobility (LOM). Table 2 shows the definition of LOM rankings based on V/C.

Table 2- LOM criteria

Level of Mobility	**V/C Ratio**
Tolerable	<0.85
Moderate	>=0.85 <1.0
Serious	>=1.0<1.25
Severe	>=1.25

2010 Existing Traffic Conditions

The existing traffic conditions are shown below. All roadway segments operate at a "Tolerable" LOM.

2010 Existing									
	Daily			AM			PM		
Road Segment	V	V/C	LOM	V	V/C	LOM	V	V/C	LOM
1	5475	0.46	Tolerable	418	0.35	Tolerable	493	0.41	Tolerable
2	7710	0.64	Tolerable	569	0.47	Tolerable	669	0.56	Tolerable
3	7297	0.61	Tolerable	501	0.42	Tolerable	645	0.54	Tolerable
4	7905	0.66	Tolerable	579	0.48	Tolerable	652	0.54	Tolerable
5	3113	0.26	Tolerable	235	0.20	Tolerable	262	0.22	Tolerable
6	2565	0.21	Tolerable	136	0.11	Tolerable	112	0.09	Tolerable
7	748	0.06	Tolerable	47	0.04	Tolerable	45	0.04	Tolerable

2011 Full Site Build-Out No Build

It is anticipated that the landfill will be at full build-out in 2011. One year of growth in background traffic results in minor increases in V/C ratio.

2011 Background No build									
	Daily			AM			PM		
Road Segment	V	V/C	LOM	V	V/C	LOM	V	V/C	LOM
1	5519	0.46	Tolerable	421	0.35	Tolerable	497	0.41	Tolerable
2	7848	0.65	Tolerable	579	0.48	Tolerable	681	0.57	Tolerable
3	7428	0.62	Tolerable	510	0.42	Tolerable	657	0.55	Tolerable
4	7988	0.67	Tolerable	585	0.49	Tolerable	659	0.55	Tolerable
5	3228	0.27	Tolerable	244	0.20	Tolerable	272	0.23	Tolerable
6	2601	0.22	Tolerable	138	0.11	Tolerable	114	0.09	Tolerable
7	800	0.07	Tolerable	50	0.04	Tolerable	48	0.04	Tolerable

2011 Full Site Build-Out Plus Site Traffic Conditions

With the addition of the opening day site-generated traffic to the 2011 background traffic, V/C ratio at the roadway segments tend to increase slightly as show below.

2011 Background + Site									
	Daily			AM			PM		
Road Segment	V	V/C	LOM	V	V/C	LOM	V	V/C	LOM
1	5627	0.47	Tolerable	433	0.36	Tolerable	509	0.42	Tolerable
2	7884	0.66	Tolerable	579	0.48	Tolerable	681	0.57	Tolerable
3	7752	0.65	Tolerable	510	0.42	Tolerable	657	0.55	Tolerable
4	8416	0.70	Tolerable	628	0.52	Tolerable	702	0.59	Tolerable
5	3269	0.27	Tolerable	248	0.21	Tolerable	276	0.23	Tolerable
6	2634	0.22	Tolerable	140	0.12	Tolerable	115	0.10	Tolerable
7	810	0.07	Tolerable	51	0.04	Tolerable	49	0.04	Tolerable

2021 Background Traffic Conditions No Build

An additional ten years of growth in the background traffic results in significant increases in the V/C ratio when compared to 2011, as shown below.

2021 Background No build									
	Daily			AM			PM		
Road Segment	V	V/C	LOM	V	V/C	LOM	V	V/C	LOM
1	5975	0.50	Tolerable	456	0.38	Tolerable	538	0.45	Tolerable
2	9378	0.78	Tolerable	692	0.58	Tolerable	814	0.68	Tolerable
3	8872	0.74	Tolerable	609	0.51	Tolerable	784	0.65	Tolerable
4	8871	0.74	Tolerable	650	0.54	Tolerable	732	0.61	Tolerable
5	4644	0.39	Tolerable	351	0.29	Tolerable	391	0.33	Tolerable
6	2987	0.25	Tolerable	158	0.13	Tolerable	130	0.11	Tolerable
7	1567	0.13	Tolerable	98	0.08	Tolerable	94	0.08	Tolerable

2021 Background Traffic Conditions Plus Site Traffic

With the addition of the site-generated traffic to the 2021 background traffic, the V/C ratio is approaching "Moderate" LOM for segments 2, 3, and 4.

2021 Background + Site									
	Daily			AM			PM		
Road Segment	V	V/C	LOM	V	V/C	LOM	V	V/C	LOM
1	6083	0.51	Tolerable	467	0.39	Tolerable	550	0.46	Tolerable
2	9414	0.78	Tolerable	708	0.59	Tolerable	830	0.69	Tolerable
3	9196	0.77	Tolerable	671	0.56	Tolerable	846	0.71	Tolerable
4	9298	0.77	Tolerable	693	0.58	Tolerable	775	0.65	Tolerable
5	4685	0.39	Tolerable	355	0.30	Tolerable	395	0.33	Tolerable
6	3020	0.25	Tolerable	161	0.13	Tolerable	132	0.11	Tolerable
7	1577	0.13	Tolerable	99	0.08	Tolerable	95	0.08	Tolerable

2040 Background Traffic Conditions No Build

By 2040, segment 2 and 3 is at a "Moderate" LOM for the PM peak hour, and "Serious" LOM for the daily traffic. Segment 4 is at a "Moderate" LOM for the daily traffic.

2040 Background No build									
	Daily			AM			PM		
Road Segment	V	V/C	LOM	V	V/C	LOM	V	V/C	LOM
1	6948	0.58	Tolerable	530	0.44	Tolerable	626	0.52	Tolerable
2	13151	1.10	Serious	971	0.81	Tolerable	1141	0.95	Moderate
3	12433	1.04	Serious	854	0.71	Tolerable	1099	0.92	Moderate
4	10824	0.90	Moderate	793	0.66	Tolerable	893	0.74	Tolerable
5	9265	0.77	Tolerable	699	0.58	Tolerable	780	0.65	Tolerable
6	3885	0.32	Tolerable	206	0.17	Tolerable	170	0.14	Tolerable
7	5624	0.47	Tolerable	353	0.29	Tolerable	338	0.28	Tolerable

2040 Background Traffic Conditions Plus Site Traffic

The addition of the site build-out traffic increases the V/C ratio, but does not result in changes to the LOM rankings. As seen in the following table, the site generated traffic slightly increases the V/C ratio. The roadway links which are projected to reach the "Moderate" or "Serious" LOM are a result of the continuing background traffic growth.

2040 Background + Site									
	Daily			AM			PM		
Road Segment	V	V/C	LOM	V	V/C	LOM	V	V/C	LOM
1	7078	0.59	Tolerable	544	0.45	Tolerable	640	0.53	Tolerable
2	13330	1.11	Serious	989	0.82	Tolerable	1161	0.97	Moderate
3	13177	1.10	Serious	928	0.77	Tolerable	1173	0.98	Moderate
4	11338	0.94	Moderate	844	0.70	Tolerable	945	0.79	Tolerable
5	9314	0.78	Tolerable	705	0.59	Tolerable	785	0.65	Tolerable
6	3926	0.33	Tolerable	209	0.17	Tolerable	172	0.14	Tolerable
7	5636	0.47	Tolerable	354	0.30	Tolerable	339	0.28	Tolerable

2040 MTP Background Traffic Conditions Plus Site Traffic

McCombs (segment 1, 2, 3, and 4) is indicated on the MTP as an eight lane super arterial. The following table shows the LOM with the recommended transportation improvements on McCombs.

2040 ***MTP*** Background + Site									
	Daily			AM			PM		
Road Segment	V	V/C	LOM	V	V/C	LOM	V	V/C	LOM
1	7078	0.15	Tolerable	544	0.11	Tolerable	640	0.13	Tolerable
2	13330	0.28	Tolerable	989	0.21	Tolerable	1161	0.24	Tolerable
3	13177	0.27	Tolerable	928	0.19	Tolerable	1173	0.24	Tolerable
4	11338	0.24	Tolerable	844	0.18	Tolerable	945	0.20	Tolerable
5	9314	0.78	Tolerable	705	0.59	Tolerable	785	0.65	Tolerable
6	3926	0.33	Tolerable	209	0.17	Tolerable	172	0.14	Tolerable
7	5636	0.47	Tolerable	354	0.30	Tolerable	339	0.28	Tolerable

Conclusions:

The segment on McCombs between State Line and Stan Roberts is projected to reach "Serious" LOM approaching the end of life year 2040 as a result of the continuing background traffic growth. With the addition of traffic from the proposed site, the V/C ratio increases slightly, but does not result in changes to the LOM rankings.

If the recommended improvements on McCombs are implemented according to the MTP, then all roadway segments operate at a "Tolerable" LOM.

TEXAS COMMISSION ON ENVIRONMENTAL QUALITY

Protecting Texas by Reducing and Preventing Pollution

October 28, 2011

Dear Applicant:

Re: TPDES Multi-Sector General Permit (TXR050000)
Notice of Intent Authorization

Your Notice of Intent application for authorization under the general permit for discharge of storm water associated with industrial activities has been received. Pursuant to authorization from the Executive Director of the Texas Commission on Environmental Quality, the Division Director of the Water Quality Division has issued the enclosed Certificate.

Please refer to the attached certificate for the identification number that was assigned to your project/site and the coverage effective date. Please use this number to reference this project/site for future communications with the Texas Commission on Environmental Quality (TCEQ).

Authorization under the Edwards Aquifer Protection Program is required before construction can begin where the site is located within the Edwards Aquifer Recharge Zone, Contributing Zone, or Contributing Zone within the Transition Zone. See http://www.tceq.state.tx.us/compliance/field_ops/eapp/program.html for additional information.

A Notice of Termination must be submitted when permit coverage is no longer needed. You may obtain a Notice of Termination form at the web site listed below. All authorizations that are active on September 1st of each year will be assessed an annual fee. The Notice of Termination must be postmarked for delivery to TCEQ on or before September 1 to avoid the annual fee assessment.

The billing statement will be mailed to the Operator in January and payment must be made within 30 days to avoid late fees. It is the responsibility of the Operator to notify the TCEQ Storm Water Processing center of any change in address supplied on the original Notice of Intent.

For questions related to the status or processing of your application you may contact the Storm Water Processing Center by email at SWPERMIT@tceq.state.tx.us or by telephone at (512) 239-3700. If you have any questions regarding coverage under this general permit or other technical issues, you may contact the storm water technical staff at (512) 239-4671 or by email at swgp@tceq.state.tx.us. Also, you may obtain information on the storm water web site at www.tceq.state.tx.us. Permit and application status information can be found on the TCEQ web site at http://www5.tceq.state.tx.us/wq_dpa/.

Sincerely,

Charles W. Maguire, Director
Water Quality Division
Texas Commission on Environmental Quality

TEXAS COMMISSION ON ENVIRONMENTAL QUALITY

Texas Pollutant Discharge Elimination System
Storm Water Multi-Sector General Permit

The Notice of Intent (NOI) for the facility listed below was received on September 19, 2011. The intent to discharge storm water associated with industrial activity under the terms and conditions imposed by the Texas Pollutant Discharge Elimination System (TPDES) storm water multi-sector general permit TXR050000 is acknowledged. Your facility's TPDES multi-sector storm water general permit number is:

TXR05L795
Coverage Effective: November 26, 2001

TCEQ's storm water multi-sector general permit requires certain storm water pollution prevention and control measures, possible monitoring and reporting, and periodic inspections. Among the conditions and requirements of this permit, you must have prepared and implemented a storm water pollution prevention plan (SWP3) that is tailored to your industrial site. As a facility authorized to discharge under the storm water multi-sector general permit, all terms and conditions must be complied with to maintain coverage and avoid possible penalties.

Project/Site Information:
RN100215599
MCCOMBS LANDFILL
13600 MCCOMBS ST
EL PASO, TX 79934-3307
EL PASO COUNTY

Operator:
CN601410244
CITY OF EL PASO
7968 SAN PAULO DR
EL PASO, TX 79907-1261

This permit expires on August 14, 2016, unless otherwise amended. If you have any questions related to processing you may contact the Storm Water Processing Center by **email at SWPERMIT@tceq.texas.gov or by telephone at (512) 239-3700**. For technical issues, you may contact the storm water technical staff by email at swgp@tceq.texas.gov or by telephone at (512) 239-4671. Also, you may obtain information on the storm water web site at http://www5.tceq.texas.gov/wq_dpa/. A copy of this document should be kept with your SWP3.

*EXPLANATION OF ZONE DESIGNATIONS

ZONE	EXPLANATION
A	Areas of 100-year flood; base flood elevations and flood hazard factors not determined.
AO	Areas of 100-year shallow flooding where depths are between one (1) and three (3) feet; average depths of flooding are shown, but no Flood Hazard Factors are determined.
AH	Areas of 100-year shallow flooding where depths are between one (1) and three (3) feet; base flood elevations are shown, but no Flood Hazard Factors are determined.
A1-A30	Areas of 100-year flood; base flood elevations and flood hazard factors determined.
A99	Areas of 100-year flood to be protected by flood protection system under construction; base flood elevations and flood hazard factors not determined.
B	Areas between limits of the 100-year flood and 500-year flood; or certain areas subject to 100-year flooding with average depths less than one (1) foot or where the contributing drainage area is less than one square mile; or areas protected by levees from the base flood. (Medium shading)
C	Areas of minimal flooding. (No shading)
D	Areas of undetermined, but possible, flood hazards.
V	Areas of 100-year coastal flood with velocity (wave action); base flood elevations and flood hazard factors not determined.
V1-V30	Areas of 100-year coastal flood with velocity (wave action); base flood elevations and flood hazard factors determined.

NOTES TO USER

Certain areas not in the special flood hazard areas (zones A and V) may be protected by flood control structures.

This map is for use in administering the National Flood Insurance Program; it does not necessarily identify all areas subject to flooding, particularly from local drainage sources of small size, or all planimetric features outside special flood hazard areas. The coastal flooding elevations shown may differ significantly from those developed by the National Weather Service for hurricane evacuation planning.

For adjoining map panels, see separately printed Index to Map Panels.

RE: McCombs Municipal Solid Waste Landfill Vertical Expansion; El Paso County

Dear Mr. Doran:

Texas Parks and Wildlife Department (TPWD) received the request for information regarding listed threatened or endangered species within or near the above-referenced proposed project. TPWD staff has reviewed the information provided and offers the following comments and recommendations concerning this project.

Please be aware that a written response to a TPWD recommendation or informational comment received by a state governmental agency may be required by state law. For further guidance, see the Texas Parks and Wildlife Code, Section 12.0011, which can be found online at http://www.statutes.legis.state.tx.us/Docs/PW/htm/PW.12.htm#12.0011. For tracking purposes, please refer to TPWD project number 16900 in any return correspondence regarding this project.

Project Description

The proposed project entails the vertical expansion of an existing landfill to increase the height from the currently permitted elevation of 4,125 feet to 4,305 feet. The existing permitted boundary of the landfill is 327 acres and is not proposed to increase. No other information about the proposed project was provided with the request.

Federal Laws

Endangered Species Act

Federally-listed animal species and their habitats are protected from "take" on any property by the Endangered Species Act (ESA). Take of a federally-listed species can be allowed if it is "incidental" to an otherwise lawful activity and

4200 SMITH SCHOOL ROAD
AUSTIN, TEXAS 78744-3291
512.389.4800
www.tpwd.state.tx.us

must be permitted in accordance with Section 7 or 10 of the ESA. Federally-listed plants are not protected from take except on lands under federal/state jurisdiction or for which a federal/state nexus (i.e., permits or funding) exists. Any take of a federally-listed species or its habitat without the required take permit (or allowance) from the U.S. Fish and Wildlife Service (USFWS) is a violation of the ESA.

A record of consultation with the USFWS in 1982 was provided with the request. That correspondence addressed potential impacts to species that were listed as threatened or endangered at the time the landfill was constructed. Please note that since 1982 the following species have been listed as threatened or endangered under the ESA and have the potential to occur in El Paso County:

Species	**Date Listed**
Least tern (*Sterna antillarum*)	05/28/1985
Northern Aplomado Falcon (*Falco femoralis septentrionalis*)	02/25/1986
Mexican Spotted Owl (*Strix occidentalis lucida*)	03/16/1993
Southwestern Willow Flycatcher (*Empidonax trailii extimus*)	02/27/1995

It is the responsibility of the project proponent to determine if adverse impacts federally-listed species are expected to occur as a result of the proposed project and consult with the appropriate agency concerning those impacts.

Recommendation: TPWD recommends SAIC assess the proposed project for potential impacts to species that are protected by the ESA. Brief descriptions of suitable habitats for these species are provided on the attached TPWD El Paso County list. If potential impacts to federally listed species are anticipated, TPWD recommends SAIC contact the USFWS Austin Ecological Services Field office at (512) 490-0057.

Migratory Bird Treaty Act

The Migratory Bird Treaty Act (MBTA) prohibits taking, attempting to take, capturing, killing, selling/purchasing, possessing, transporting, and importing of migratory birds, their eggs, parts and nests, except when specifically authorized by the Department of the Interior. This protection applies to most native bird species, including ground nesting species. The US Fish and Wildlife Service (USFWS) Migratory Bird Office can be contacted at (505) 248-7882 for more information on potential impacts to migratory birds.

Recommendation: If migratory bird species are found nesting on or adjacent to the project area, they must be dealt with in a manner consistent with the MBTA. TPWD recommends excluding vegetation clearing activities during the general bird nesting season, March through August, to avoid adverse impacts to this group. If clearing vegetation during the migratory bird nesting season is unavoidable, TPWD recommends the facility survey the area proposed for disturbance to ensure that no nests with eggs or young will be disturbed by operations. Any vegetation (trees, shrubs, and grasses) where occupied nests are located should not be disturbed until the eggs have hatched and the young have fledged.

State Laws

Parks and Wildlife Code, Section 68.015

Section 68.015 of the Parks and Wildlife Code regulates state-listed species. Please note that there is no provision for take (incidental or otherwise) of state-listed species. A copy of *TPWD Guidelines for Protection of State-Listed Species*, which includes a list of penalties for take of species, is attached for your reference. State-listed species may only be handled by persons with a scientific collection permit obtained through TPWD. For more information on this permit, please contact the Wildlife Permits Office at (512) 389-4647.

Sparse vegetation consisting of grass, cactus, and scattered brush possibly found in the project area could potentially support the following state-listed threatened species:

- Texas horned lizard (*Phrynosoma cornutum*)
- Mountain short-horned lizard (*P. hernandesi*).

An additional indication of suitable habitat for the Texas horned lizard would be the presence of its primary food source, the Harvester ant (*Pogonomyrmex* sp.). Texas horned lizards and Mountain short-horned lizards are generally active in this part of Texas from March through September.

Recommendation: TPWD recommends avoiding disturbance of the Mountain short-horned lizard, Texas horned lizard, and colonies of the Harvester ant during clearing and construction. TPWD recommends a biological monitor be present during construction to try to relocate protected species if found. If the presence of a biological monitor during construction is not feasible, state-listed threatened species observed during construction should be allowed to safely leave the site.

A mixture of cover, food sources, and open ground is important to the Mountain short-horned lizard, Texas horned lizard, and Harvester ant. Disturbed areas within suitable habitat for these species should be revegetated with site-specific native, patchy vegetation rather than sod-forming grasses. TPWD recommends review and implementation of the attached monitoring and management guidelines for horned lizards.

Species of Concern

In addition to state- and federally-protected species, TPWD tracks special features, natural communities, and rare species that are not listed as threatened or endangered. These species and communities are tracked in the Texas Natural Diversity Database (TXNDD), and TPWD actively promotes their conservation. TPWD considers it important to evaluate and, if necessary, minimize impacts to rare species and their habitat to reduce the likelihood of endangerment.

Based on the project description, site location, a review of the TXNDD, and publicly-available aerial photographs, the following species of concern could be impacted as a result of the proposed project:

- Western Burrowing Owl (*Athene cunicularia hypugaea*)
- Desert night-blooming cereus (*Peniocereus greggii* var *greggii*)

A record of the Desert night-blooming cereus has been documented possibly within 1.5 miles of the project site. A printout of this occurrence record is attached for your reference.

Recommendation: If during construction the project area is found to contain rare species, natural plant communities, or special features, TPWD recommends that precautions be taken to avoid impacts to them.

Western Burrowing Owls reside primarily in open areas with short vegetation and bare ground, sometimes including areas near human habitation. They are dependent on the presence of fossorial (digging and burrowing) mammals, such as prairie dogs and ground squirrels, whose burrows are used for nesting and roosting. Burrowing owls residing in El Paso and surrounding counties are not only summer (breeding) residents but many owls stay in the El Paso region as winter residents. As stated above, the MBTA prohibits the intentional and unintentional take of migratory birds (including ground nesting species), their nests, and eggs. If mammal burrows would be disturbed as a result of the proposed project, TPWD recommends they be surveyed for burrowing owls. If nesting owls are found, disturbance should be avoided until the eggs have hatched and the young have fledged.

Please note that absence of TXNDD information in an area does not imply that a species is absent from that area. Given the small proportion of public versus private land in Texas, the TXNDD does not include a representative inventory of rare resources in the state. Although it is based on the best data available to TPWD regarding rare species, the data from the TXNDD do not provide a definitive statement as to the presence, absence or condition of special species, natural communities, or other significant features within your project area. These data are not inclusive and **cannot be used as presence/absence data.** They represent species that could potentially be in your project area. This information cannot be substituted for on-the-ground surveys. The TXNDD is updated continuously. As the project progresses and for future projects, please request the most current and accurate information at txndd@tpwd.state.tx.us.

Recommendation: Please review the attached TPWD county list of rare and protected species for El Paso County, as rare species in addition to those discussed above could be present depending upon habitat availability. These lists are also available online at http://www.tpwd.state.tx.us/landwater/land/maps/gis/ris/endangered_species/. The USFWS should be contacted for species occurrence data, guidance, permitting, survey protocols, and mitigation for federally listed species. For the USFWS rare species lists by county please visit http://www.fws.gov/endangered/.

Determining the actual presence of a species in a given area depends on many variables including daily and seasonal activity cycles, environmental activity cues, preferred habitat, transiency and population density (both wildlife and human). The absence of a species can be demonstrated only with great difficulty and then only with repeated negative observations, taking into account all the variable factors contributing to the lack of detectable presence. If encountered during construction, measures should be taken to avoid impacting wildlife.

I appreciate the opportunity to review and comment on this project. Please call me at (512) 389-4579 if we may be of further assistance.

Sincerely,

Julie C. Wicker

Protection of State-Listed Species
Texas Parks and Wildlife Department Guidelines

Protection of State-Listed Species

State law prohibits any take (incidental or otherwise) of state-listed species. State-listed species may only be handled by persons possessing a **Scientific Collecting Permit** or a **Letter of Authorization** issued to relocate a species.

- **Section 68.002 of the Texas Parks and Wildlife (TPW) Code** states that species of fish or wildlife indigenous to Texas are endangered if listed on the United States List of Endangered Native Fish and Wildlife or the list of fish or wildlife threatened with statewide extinction as filed by the director of Texas Park and Wildlife Department. Species listed as Endangered or Threatened by the Endangered Species Act are protected by both Federal and State Law. The State of Texas also lists and protects additional species considered to be threatened with extinction within Texas.

- **Animals** - Laws and regulations pertaining to state-listed endangered or threatened animal species are contained in **Chapters 67 and 68 of the Texas Parks and Wildlife (TPW) Code** and **Sections 65.171 - 65.176 of Title 31 of the Texas Administrative Code (TAC).** State-listed animals may be found at **31 TAC §65.175 & 176.**

- **Plants** - Laws and regulations pertaining to endangered or threatened plant species are contained in **Chapter 88 of the TPW Code and Sections 69.01 - 69.9 of the TAC.** State-listed plants may be found at **31 TAC §69.8(a) & (b).**

Prohibitions on Take of State Listed Species

Section 68.015 of the TPW Code states that no person may capture, trap, take, or kill, or attempt to capture, trap, take, or kill, endangered fish or wildlife.

Section 65.171 of the Texas Administrative Code states that except as otherwise provided in this subchapter or **Parks and Wildlife Code, Chapters 67 or 68,** no person may take, possess, propagate, transport, export, sell or offer for sale, or ship any species of fish or wildlife listed by the department as endangered or threatened.

"Take" is defined in **Section 1.101(5) of the Texas Parks and Wildlife Code** as:

> *"Take," except as otherwise provided by this code, means collect, hook, hunt, net, shoot, or snare, by any means or device, and includes an attempt to take or to pursue in order to take.*

Penalties

The penalties for take of state-listed species **(TPW Code, Chapter 67 or 68)** are:

- 1ST Offense = Class C Misdemeanor:
  $25-$500 fine

- One or more prior convictions = Class B Misdemeanor
  $200-$2,000 fine and/or up to 180 days in jail.

- Two or more prior convictions = Class A Misdemeanor
  $500-$4,000 fine and/or up to 1 year in jail.

Restitution values apply and vary by species. Specific values and a list of species may be obtained from the TPWD Wildlife Habitat Assessment Program.

WHAT'S HAPPENED TO ALL THE HORNY TOADS?

Everyone loves horny toads, but for many Texans, the fierce-looking, yet amiable, reptiles are only a fond childhood memory. Once common throughout most of the state, horned lizards have disappeared from many parts of their former range.

A statewide survey conducted by the Horned Lizard Conservation Society in 1992 confirmed many Texans' personal experiences—in the latter part of the 20th century the Texas Horned Lizard nearly disappeared from the eastern third of Texas and many respondents reported that horned lizards were increasingly rare in Central and North Texas. Only in West and South Texas do populations seem somewhat stable.

Many factors have been proposed as culprits in the disappearance of horned lizards, often fondly called "horny toads," including collection for the pet trade, spread of the red imported fire ant, changes in agricultural land use, habitat loss and fragmentation as a result of urbanization, and environmental contaminants. For the most part, however, the decline of horned lizards has remained a mystery with little understanding of management actions that could be taken to reverse it. Even less is known about the status of our other two horned lizard species—the Round-tailed Horned Lizard and the Greater Short-horned Lizard.

But you can help! Through participation in Texas Horned Lizard Watch as a citizen scientist, you can collect data and observations about the presence or absence of horned lizards and habitat characteristics on your monitoring site. The data you provide to TPWD, ***even if you don't find horned lizards***, will help us understand how they are doing and offer some insights for people wishing to manage habitats for horned lizards. If you are a property owner, then keeping these management guidelines in mind can help you to enhance or perhaps even recruit horned lizard populations on your property, while at the same time benefitting other native wildlife. There's something everyone can do to help out horny toads!

Texas Horned Lizard

D. MARTIN

ABOUT HORNED LIZARDS

Appearance

Horned lizards are named for the crown of horns found on their heads, the size and number of which vary among species. Although often called horned toads, horny toads, or even horned frogs because of their wide, flattened bodies (their scientific name *Phrynosoma* actually means "toad-body"), they are not amphibians like other toads, but are reptiles with scales, claws and young produced on land. More than a dozen different species of horned lizards are found throughout western North America.

Three horned lizard species call Texas home, with the most widespread being the Texas Horned Lizard, or the familiar "horny toad." The geographic range of these species can overlap in West Texas, but they can each be readily distinguished from each other by the following characteristics.

LEE ANN LINAM

D. MARTIN

D. MARTIN

Texas Horned Lizard

Phrynosoma cornutum

Horns – two prominent horns at the rear and center of the skull
Scales – two rows of spiky fringe scales on the side of the body
Coloring – gray to brown to rust, with dark spots in rows down the back, a light central stripe, and dark lines radiating from the eye.
Length – 3.5 to 5 inches
Range – most of Texas, though now nearly gone from the eastern third

Round-tailed Horned Lizard

Phrynosoma modestum

Horns – four horns of medium length lined up on the back of the head
Scales – few enlarged scales on the body, sides without spiky fringe
Coloring – white to gray, brown or pink, with dark blotches at the legs and neck; bands on tail
Length – 3 to 4 inches
Range – rocky areas in the western third of Texas

Greater Short-horned Lizard

Phrynosoma hernandesi

Horns – robust head that is wider than long and heart-shaped, back of the head is tipped only with small horns
Scales – one row of spiky fringe scales along the side of the body
Coloring – variable colors and patterns ranging from simple brown or grey to intricate patterns of bright colors including orange, yellow, white, red, blue and green
Length – 3.5 to 6 inches
Range – only higher elevations, in the forests of the Davis and Guadalupe mountains of West Texas

TEXAS SPINY LIZARD

Another similar group of lizards occurs in Texas, the spiny lizards. Spiny lizards are sometimes confused with horned lizards because of the spiky scales found on their bodies and heads; however, the spiny lizards are much more slender with a longer tail. In addition, they tend to spend more time climbing, whereas horned lizards spend most of their time on the ground.

Life History

Horned lizards are usually found in flat, open terrain, with sparse plant cover, although in the eastern portion of their distribution, vegetation cover may be somewhat thicker. They utilize mammal burrows, rock piles or clumps of vegetation for cover and may excavate shallow burrows in loose soils or scoop out a shallow depression in which to hide.

Horned lizards primarily eat harvester ants (also called big red ants), but their diet also includes termites, other native ants, other insects, spiders and sowbugs. Horned lizards or their droppings can sometimes be found near the beds of harvester ants, and an individual can consume 70–100 ants per day (one reason they are difficult to maintain in captivity!).

Horned lizards require warm temperatures to stimulate their appetite and activity. They sometimes begin their day by exposing only their heads to sunlight while keeping their bodies buried. Later, they will often be seen in a flattened body posture sunning themselves in open areas. They are not usually active at night or when temperatures fall below 75° F. In general, they are seen only in late spring through early fall and tend to hibernate a few inches underground from September/October to March/April.

Mating occurs soon after emergence from hibernation. The female digs a hole 6 to 8 inches deep and lays 13 to 50 eggs (6 to 18 for Round-tailed Horned Lizards), which are incubated by the warmth of the soil. Depending on ground temperatures, young horned lizards about 3/4-inch in length may begin to hatch 5 to 9 weeks later. The Greater Short-horned Lizard, which lives in cooler, higher-altitude climates, is unique among our species in giving birth to live young!

Texas Horned Lizards and Short-horned Lizards may live 5 to 8 years, while Round-tailed Horned Lizards are thought to live only 2 to 3 years. Although snakes, mammals and birds prey on them, horned lizards have developed some unique defenses. Their spiky appearance and coloration help Texas and Short-horned lizards to blend into the local vegetation, while the color and shape of the Round-tailed Horned Lizard actually help it to look like a rock! In addition to the deterrence that the horns on the head may provide to predators, horned lizards can inflate themselves to a larger apparent size or may tilt their body to appear larger. Finally, the horned lizard is renowned for its ability to shoot

WHAT ARE HARVESTER ANTS?

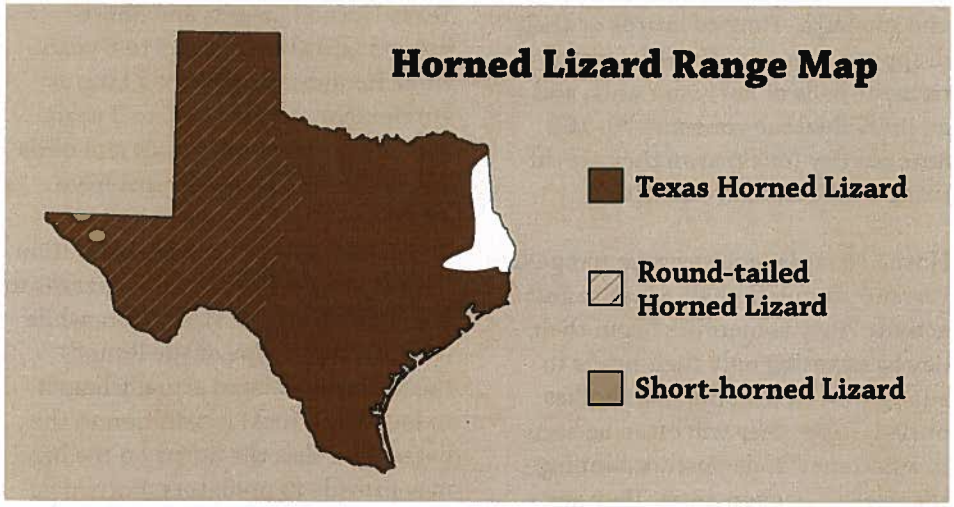
Harvester ants belong to the genera *Pogonomyrmex* or *Ephebomyrmex*. Twelve species of harvester ants are found in Texas, and the Red Harvester Ant (*Pogonomyrmex barbatus*) is the most widespread. Red harvester ants are easily identified by their large size (up to a half inch) and generally conspicuous mound. These ants clear vegetation, forming a large circular pattern of bare ground around their nest. This bare ground is often covered with small pebbles dug from within the nest itself. The mound usually has one main entrance/exit hole in the center of the cleared area. Extending in various directions from the main mound are foraging trails leading to various foraging zones. Harvesters, as the name implies, harvest seeds. Grass seeds make up the majority of their diet, and the husks of harvested seeds often surround harvester ant mounds.

MAYO

a stream of blood from its eye when under extreme stress (actually from ruptured blood vessels in the sinuses near the eyes). A chemical in the blood is especially distasteful to canine predators. Texas Horned Lizards and Short-horned Lizards are known to engage in blood-squirting, while the Round-tailed Horned Lizard does not.

Sometimes a horned lizard sign such as scat (or droppings) is much more visible than the species itself. Horned lizard scat is a dark brown oblong pellet that is straight or slightly curved. A white uric acid tip is often very prominent. Ant heads and other body parts are noticeable in the scat, especially when the scat is broken apart. The scat usually looks very large in relation to the lizard from which it came, ranging from 1/2 to 1-1/2 inches in length and 1/4 to 3/8 inch in diameter. Scat of other lizards have the uric acid tip; however, the shape of the scat is much less symmetrical and it will not contain a high percentage of ants.

NEWSOM



Protected Status

Texans have a long history of concern for horned lizards. In 1967, the state legislature protected Texas Horned Lizards from the pet trade (horned lizards do not survive well in captivity), and in 1977, Texas Parks and Wildlife Department placed both the Texas Horned Lizard and the Greater Short-horned Lizard on the state threatened species list. In 1993, a group of schoolchildren successfully petitioned the Texas Legislature to name the Texas Horned Lizard the official state reptile. Though not listed as threatened or endangered, Round-tailed Horned Lizards receive some attention/regulation through the state's nongame permit process.

MANAGEMENT OF HORNED LIZARDS

Many Texans are interested in having more horned lizards on their property. Although many people inquire about translocating or breeding horned lizards for release, unfortunately, initial research has not been very successful with these efforts and additional conservation questions need to be answered. In addition, because Texas Horned Lizards and Short-horned Lizards are listed as threatened species, anyone handling these species or attempting to do this must obtain a scientific permit. Horned lizards cannot survive and thrive without appropriate habitat, and probably the best strategy for bringing back horned lizards is to first restore or create suitable habitat that can support and conserve native ant populations as well as horned lizards.

Horned lizards in Texas can be found in a variety of habitats; however, researchers have noted several similarities among occupied habitat.

- First, horned lizards tend to be found in "patchy" habitat that is characterized by areas of bare ground (~40 percent) interspersed with native vegetation. This open ground allows horned lizards room for movement and basking, and it provides ants open areas for colony establishment.
- Second, Texas Horned Lizards seem to prefer sandy loam soils that are more than 2/3 sand and less than 15 percent clay. Loose, well-drained soils are more suitable for burrowing, hibernating and nesting.
- Third, horned lizards in Texas are usually found where native ants are abundant. Harvester (or "red") ants in the genus *Pogonomyrmex* are often very evident, although horned lizards also eat other native ants and insects.

One horned lizard can use five to six acres of habitat over the course of its activities, often feeding at a number of different harvester ant mounds. There is a minimal amount of overlap with other adult horned lizards. A viable population of horned lizards may thus require a substantial amount of suitable habitat.

MANAGEMENT GUIDELINES

The following management guidelines for horned lizards are adapted from a 1998 publication, *Management of Texas Horned Lizards*, written by Scott E. Henke and Wm. Scott Fair, and published by the Caesar Kleberg Wildlife Research Institute of Texas A&M University–Kingsville as Wildlife Management Bulletin No. 2.

1. **Develop and maintain a habitat that contains a diversity of native plant species –** A diverse community of native plants will attract a diverse community of invertebrates. Such a variety of insects may be especially important to juvenile horned lizards. If you are interested in reclaiming a previous agricultural area or in landscaping at your residence, focus on native bunchgrasses, such as bluestems, forbs and shrubs. Bunchgrasses form clumps that allow horned lizards to easily move among the grass clumps; whereas carpet grasses form a thick mat that can impede horned lizard movement. Native grasses also produce seeds that are good food sources for harvester ants.

2. **Create a mosaic habitat of open areas intermixed within more dense cover –** Such a patchy environment will give horned lizards areas in which to warm or cool themselves, allow them room for movement, and offer sufficient escape cover from predators. You may also wish to create 1-square-yard areas devoid of any vegetation and ground litter. These spots may serve as valuable basking areas for horned lizards, and newly fertilized harvester ant queens need bare ground in which to establish new colonies. Grazing, burning, mowing, and scraping can help create and maintain the mosaic habitat desired.

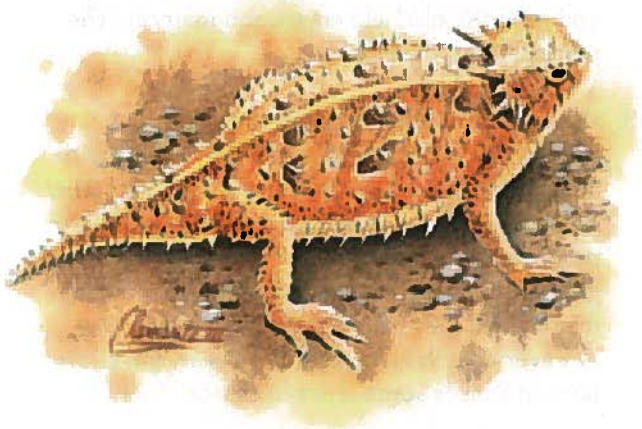
3. **Use prescribed fires to remove ground litter** – Horned lizards usually avoid areas with substantial dead vegetation on the ground (also called litter) because the litter can impede their movement. Burning is a useful tool to decrease ground litter and create open ground. Burning in small patches on a rotational basis, so that not every patch is burned every year, can allow horned lizards some areas to escape. In addi-

tion, conducting burns during the cool season (late winter/early spring) results in cooler fires, and research suggests that hibernating lizards can survive such fires while burrowed underground. Local Natural Resource Conservation Service staff can provide site-specific guidance on prescribed burning.

4. **Avoid overgrazing by livestock** – Horned lizards do not appear to be negatively affected by low to moderate grazing of livestock, and grazing may help increase some plant diversity and open areas. On the other hand, very heavy stocking rates can reduce needed cover and result in direct mortality of horned lizards. Use of a rotational grazing scheme can help create the desired mosaic of open areas and vegetative cover.

5. **Avoid road maintenance and limit traffic during the horned lizard active season** – Horned lizards make frequent use of roadsides, especially unpaved secondary roads, for basking, resting, and bedding sites. If possible, avoid disking or grading roads between mid-March and mid-October. In addition, vehicular strikes can be a significant mortality factor for horned lizards. Slower speeds and caution should be exhibited during the active season for horned lizards, especially in the mornings and late afternoons. If drivers are cautious, however, road-cruising can be a valuable way to survey horned lizard populations.

6. **Avoid the use of broadcast pesticides** – Pesticides could kill horned lizards directly by accumulating toxins within their body or indirectly by killing harvester ants and other valuable insects. If pesticides are needed, then spot treatment is recommended rather than broadcast application.



7. **Manage ant populations** – Findings from Texas Horned Lizard Watch indicate that efforts should be made to encourage native ant populations and discourage red imported fire ants. The first step should be to reduce red imported fire ant populations; however, fire ant control methods should be chosen carefully, as some pesticides used to kill fire ants can also kill native ants and other insects. In a small area, individual fire ant mound treatments, either with pesticides, organic mixes or soapy boiling water, can be used. When baits are used, application late in the day on the fire ant mound can increase the chances that fire ants will pick up bait and native ants will not. On larger acreages or with severe infestations, a broadcast treatment may be needed; however, steps can be taken to minimize the impact of such treatments on native ants. Try to find a bait that uses an active ingredient, such as Spinosad, that does not affect harvester ants. Several researchers suggest placing broadcast pesticides in small containers, such as film canisters that have small holes drilled in the container or its lid. The holes should be no larger than 1/16-inch in diameter so that fire ants can enter the container, but harvester ants cannot.

   As noted above, native ants can be encouraged by establishing native grasses and scattered patches of bare ground. Some landowners also choose to "feed" their harvester ant populations by providing native seed, oat flakes, crushed peanuts, or similar items within the foraging area of the mound.

8. **Remove feral domesticated predators** – Feral cats and dogs, along with pets, are predators of horned lizards. Keep pets from "hunting" in horned lizard habitat. Feral animals can be removed; you may wish to contact the Humane Society for assistance or suggestions. Keep in mind that wild avian predators, such as roadrunners or shrikes, are protected by federal law and cannot be killed or trapped; however, providing plenty of escape cover can help horned lizards survive among these natural predators.

HOW TO MONITOR HORNED LIZARDS

There are two ways you can participate in Texas Horned Lizard Watch, either by searching a site or setting up a transect. Please note that each survey type has its own unique data form.

Site Surveys

Site surveys can take place anywhere, from your backyard to your hunting ranch to your favorite state park. The enclosed data sheet asks you to provide information about the site location and its habitat and then provides a table where you can list information about each horned lizard (or horned lizard scat) seen. Feel free to submit maps or photos to supplement your information and to make copies of the data sheet if needed. You can survey as many different sites as you like; simply fill out a separate site form for each site.

For best results, we recommend that you visit your site at least five times between May and September; however, we are happy to accept data from sites that you visit less often. You can even fill out this form when you happen to spot a horned lizard by chance. Simply let us know how many hours you spent visiting the site, so that we can get an idea of the survey effort.

Transects

Transects are a more quantitative method for monitoring species and require a more formal survey effort. The benefits of transects are that we can convert results to density estimates and thus compare horned lizard populations at different sites.

To conduct a Texas Horned Lizard transect you need to set up a route that is at least 3 miles long. The route can follow unpaved roads or trails or be of your own design. Walk, ride or drive the route, recording all Texas horned lizards and ant beds that occur within 3 feet of your route on either side. (If driving, be sure to keep speeds under 15 mph and stop and check the identification of any horned lizards seen.) Mark your transect location on a map if possible. Transects should be conducted at least five times between May and September if possible.

Submitting Data

Data forms can be mailed, faxed, or scanned and e-mailed. We would like to receive your datasheet *even if you do not see horned lizards*. Not finding horned lizards is as important as finding them, because that helps us understand the types of sites or conditions where horned lizards are missing.

Additional Monitoring Notes

Certain conditions apply to both methods. You should try to make sure that your surveys are conducted under sunny, or partly sunny, dry weather conditions when temperatures are 80-95° F and winds are light or moderate. One good indicator of horned lizard activity is to check to see whether harvester ants are active. Ideally, your five survey efforts should be at least several weeks apart (although you may conduct additional surveys more frequently). If you do visit a site more frequently, then you may want to collect any horned lizard scat you encounter so that you don't recount it on subsequent visits. Scat can also be sent in with your data sheets as verification.

The Texas Horned Lizard and the Short-horned Lizard are listed as threatened by Texas Parks and Wildlife, primarily to protect them from commercial exploitation. Because of this designation, you should not collect or move horned lizards that you encounter on your survey efforts.

Finally, be sure to send in your survey forms, even if you do not see any horned lizards. If you have any uncertainty about identification of the lizards or scat you see, don't hesitate to take a photo and send it to us.

IMPORTANT:

ABOUT THE LANDOWNER ACCESS REQUEST FORM

Texas Parks and Wildlife cannot use data collected from private land unless written permission is received from the landowner.

All Texas Horned Lizard Watch volunteers must send in a completed Landowner Access Request Form for any data collected from private land. This applies even if you are monitoring your own property.

Please respect the rights of private property owners during the course of your volunteer efforts.

TEXAS PARKS & WILDLIFE

Texas Horned Lizard Watch

Landowner Access Request Form

To the landowner:

_____ (volunteer name) is participating as a volunteer in Texas Horned Lizard Watch. Texas Horned Lizard Watch is a monitoring program that uses citizen volunteers to gather data about the status and health of our state reptile. Texas Parks and Wildlife is very pleased to have the assistance of concerned Texans in watching over the health of the horny toad.

We have, however, instructed our volunteers that they cannot collect data on private land without the approval of the private landowner. Accordingly, we have prepared this form for your approval. The sections described below are the releases that we and our volunteers are required to obtain from you under Section 12.103 of the Texas Parks and Wildlife Code. If you are willing, then please sign one or both sections and provide a copy to our volunteer.

1. **Use of information**
   This documents my approval for TPWD volunteers and employees to use site-specific information from the property I own or manage. This may include placing that information onto a topographic map and entering the information into a department database. Thus, the information could be viewed by the public.

   _____ _____
   (Landowner or authorized agent signature) (Date)

2. **Reporting information**
   This also documents my approval for TPWD volunteers and employees to report (such as in publications or technical reports) the above approved information in a manner that permits identification of the location of the specific parcel of property that I own or manage.

   _____ _____
   (Landowner or authorized agent signature) (Date)

3. **Other Conditions**
   If there are any conditions that apply to this approval, please specify and initial below.

   _____
   _____
   _____

Name and Address: (of landowner or authorized agent)

NONGAME AND ENDANGERED SPECIES CONSERVATION FUND

The "Special Fund" was created by the Texas Legislature in 1983 to underwrite the conservation and management work performed on Texas' nongame and endangered wildlife. This fund, sustained entirely by voluntary contributions, has provided support for a variety of projects benefiting nongame and endangered species. For more information on this fund, call the TPWD Wildlife Diversity program at (800) 792-1112.

Texas conservation license plates help fund conservation efforts in the state. The most popular plate features a Texas horned lizard and provides funding for wildlife diversity projects, including horned lizard research. **http://conservation-plate.org/**

This information is for your assistance only; due to continuing data updates, vulnerability of private land to trespass and of species to disturbance or collection, **please refer all requesters to our office to obtain the most current information available.** Also, please note, identification of a species in a given area does not necessarily mean the species currently exists at the point or area indicated.

LEGAL STATUS AND CONSERVATION RANKS

FEDERAL STATUS (as determined by the US Fish and Wildlife Service)

LE	Listed Endangered
LT	Listed Threatened
PE	Proposed to be listed Endangered
PT	Proposed to be listed Threatened
PDL	Proposed to be Delisted (Note: Listing status retained while proposed)
SAE, SAT	Listed Endangered on basis of Similarity of Appearance, Listed Threatened on basis of Similarity of Appearance
DL	Delisted Endangered/Threatened
C	Candidate. USFWS has substantial information on biological vulnerability and threats to support proposing to list as threatened or endangered. Data are being gathered on habitat needs and/or critical habitat designations.
C*	C, but lacking known occurrences
C**	C, but lacking known occurrences, except in captivity/cultivation
XE	Essential Experimental Population
XN	Non-essential Experimental Population
Blank	Species is not federally listed

TX PROTECTION (as determined by the Texas Parks and Wildlife Department)

E	Listed Endangered
T	Listed Threatened
Blank	Species not state-listed

GLOBAL RANK (as determined by NatureServe)

G1	Critically imperiled globally, extremely rare, typically 5 or fewer viable occurrences
G2	Imperiled globally, very rare, typically 6 to 20 viable occurrences
G3	Very rare and local throughout range or found locally in restricted range, typically 21 to 100 viable occurrences
G4	Apparently secure globally
G5	Demonstrably secure globally
GH	Of historical occurrence through its range
GU	Possibly in peril range-wide, but status uncertain
G#G#	Ranked within a range as status uncertain
GX	Apparently extinct throughout range
Q	Rank qualifier denoting taxonomic assignment is questionable
#?	Rank qualifier denoting uncertain rank
C	In captivity or cultivation only
G#T#	"G" refers to species rank; "T" refers to variety or subspecies rank

STATE (SUBNATIONAL) RANK (as determined by the Texas Parks and Wildlife Department)

S1	Critically imperiled in state, extremely rare, vulnerable to extirpation, typically 5 or fewer viable occurrences
S2	Imperiled in state, very rare, vulnerable to extirpation, typically 6 to 20 viable occurrences
S3	Rare or uncommon in state, typically 21 to 100 viable occurrences
S4	Apparently secure in State
S5	Demonstrably secure in State
S#S#	Ranked within a range as status uncertain
SH	Of historical occurrence in state and may be rediscovered
SU	Unrankable – due to lack of information or substantially conflicting information
SX	Apparently extirpated from State
SNR	Unranked – State status not yet assessed
SNA	Not applicable – species id not a suitable target for conservation activities
?	Rank qualifier denoting uncertain rank in State

Revised 1 Apr 2008

ELEMENT OCCURRENCE RECORD

Element Occurrence Record (EOR) Spatial and tabular record of an area of land and/or water in which a species, natural community, or other significant feature of natural diversity is, or was, present and associated information; may be a single contiguous area or may be comprised of discrete patches or subpopulations

Occurrence # Unique number assigned to each occurrence of each element when added to the NDD

LOCATION INFORMATION

Watershed Code Eight digit numerical code determined by US Geological Survey (USGS)

Watershed Name of watershed as determined by USGS

Quadrangle Name of USGS topographical map

Directions Directions to geographic location where occurrence was observed, as described by observer or in source

SURVEY INFORMATION

First/Last Observation Date a particular occurrence was first/last observed; refers only to species occurrence as noted in source and does not imply the first/last date the species was present

Survey Date If conducted, date of survey

EO Type State rank qualifiers:

- **M** Migrant – species occurring regularly on migration at staging areas, or concentration along particular corridors; status refers to the transient population in the State
- **B** Qualifier indicating basic rank refers to the breeding population in State
- **N** Qualifier indicating basic rank refers to the non-breeding population in State

EO Rank

A	Excellent	**AI**	Excellent, Introduced
B	Good	**BI**	Good, Introduced
C	Marginal	**CI**	Marginal, Introduced
D	Poor	**DI**	Poor, Introduced
E	Extant/Present	**EI**	Extant, Introduced
H	Historical/No Field Information	**HI**	Historical, Introduced
X	Destroyed/Extirpated	**XI**	Destroyed, Introduced
O	Obscure	**OI**	Obscure, Introduced

EO Rank Date Latest date EO rank was determined or revised

Observed Area Acres, unless indicated otherwise

COMMENTS

Description General physical description of area and habitat where occurrence is located, including associated species, soils, geology, and surrounding land use

Comments Comments concerning the quality or condition of the element occurrence at time of survey

Protection Comments Observer comments concerning legal protection of the occurrence

Management Comments Observer comments concerning management recommendations appropriate for occurrence conservation

DATA

EO Data Biological data; may include number of individuals, vigor, flowering/fruiting data, nest success, behaviors observed, or unusual characteristic, etc.

SITE

Site Name Title given to site by surveyor

MANAGED AREA INFORMATION

Managed Area Name Place name or (on EOR printout) name of area when the EO is located within or partially within an area identified for conservation, such as State or Federal lands, nature preserves, parks, etc.

Alias Additional names the property is known by

Acres Total acreage of property, including non-contiguous tracts

Manager Contact name, address, and telephone number for area or nearest area land steward

Please use one of the following citations to credit the source for the printout information:

Revised 1 Apr 2008

EL PASO COUNTY

AMPHIBIANS

		Federal Status	State Status
Northern leopard frog	*Rana pipiens*		

streams, ponds, lakes, wet prairies, and other bodies of water; will range into grassy, herbaceous areas some distance from water; eggs laid March-May and tadpoles transform late June-August; may have disappeared from El Paso County due to habitat alteration

BIRDS

		Federal Status	State Status
American Peregrine Falcon	*Falco peregrinus anatum*	DL	T

year-round resident and local breeder in west Texas, nests in tall cliff eyries; also, migrant across state from more northern breeding areas in US and Canada, winters along coast and farther south; occupies wide range of habitats during migration, including urban, concentrations along coast and barrier islands; low-altitude migrant, stopovers at leading landscape edges such as lake shores, coastlines, and barrier islands.

Arctic Peregrine Falcon	*Falco peregrinus tundrius*	DL	

migrant throughout state from subspecies' far northern breeding range, winters along coast and farther south; occupies wide range of habitats during migration, including urban, concentrations along coast and barrier islands; low-altitude migrant, stopovers at leading landscape edges such as lake shores, coastlines, and barrier islands.

Baird's Sparrow *Ammodramus bairdii*

shortgrass prairie with scattered low bushes and matted vegetation; mostly migratory in western half of State, though winters in Mexico and just across Rio Grande into Texas from Brewster through Hudspeth counties

Ferruginous Hawk *Buteo regalis*

open country, primarily prairies, plains, and badlands; nests in tall trees along streams or on steep slopes, cliff ledges, river-cut banks, hillsides, power line towers; year-round resident in northwestern high plains, wintering elsewhere throughout western 2/3 of Texas

Interior Least Tern	*Sterna antillarum athalassos*	LE	E

subspecies is listed only when inland (more than 50 miles from a coastline); nests along sand and gravel bars within braided streams, rivers; also know to nest on man-made structures (inland beaches, wastewater treatment plants, gravel mines, etc); eats small fish and crustaceans, when breeding forages within a few hundred feet of colony

Mexican Spotted Owl	*Strix occidentalis lucida*	LT	T

remote, shaded canyons of coniferous mountain woodlands (pine and fir); nocturnal predator of mostly small rodents and insects; day roosts in densely vegetated trees, rocky areas, or caves

Montezuma Quail *Cyrtonyx montezumae*

open pine-oak or juniper-oak with ground cover of bunch grass on flats and slopes of semi-desert mountains and hills; travels in pairs or small groups; eats succulents, acorns, nuts, and weed seeds, as well as various invertebrates

EL PASO COUNTY

BIRDS

		Federal Status	State Status
Northern Aplomado Falcon	*Falco femoralis septentrionalis*	LE	E

open country, especially savanna and open woodland, and sometimes in very barren areas; grassy plains and valleys with scattered mesquite, yucca, and cactus; nests in old stick nests of other bird species

Peregrine Falcon	*Falco peregrinus*	DL	T

both subspecies migrate across the state from more northern breeding areas in US and Canada to winter along coast and farther south; subspecies (F. p. anatum) is also a resident breeder in west Texas; the two subspecies' listing statuses differ, F.p. tundrius is no longer listed in Texas; but because the subspecies are not easily distinguishable at a distance, reference is generally made only to the species level; see subspecies for habitat.

Prairie Falcon *Falco mexicanus*

open, mountainous areas, plains and prairie; nests on cliffs

Snowy Plover *Charadrius alexandrinus*

formerly an uncommon breeder in the Panhandle; potential migrant; winter along coast

Southwestern Willow Flycatcher	*Empidonax traillii extimus*	LE	E

thickets of willow, cottonwood, mesquite, and other species along desert streams

Sprague's Pipit	*Anthus spragueii*	C

only in Texas during migration and winter, mid September to early April; short to medium distance, diurnal migrant; strongly tied to native upland prairie, can be locally common in coastal grasslands, uncommon to rare further west; sensitive to patch size and avoids edges.

Western Burrowing Owl *Athene cunicularia hypugaea*

open grasslands, especially prairie, plains, and savanna, sometimes in open areas such as vacant lots near human habitation or airports; nests and roosts in abandoned burrows

Western Snowy Plover *Charadrius alexandrinus nivosus*

uncommon breeder in the Panhandle; potential migrant; winter along coast

Western Yellow-billed Cuckoo	*Coccyzus americanus occidentalis*	C;NL

status applies only to western population beyond the Pecos River Drainage; breeds in riparian habitat and associated drainages; springs, developed wells, and earthen ponds supporting mesic vegetation; deciduous woodlands with cottonwoods and willows; dense understory foliage is important for nest site selection; nests in willow, mesquite, cottonwood, and hackberry; forages in similar riparian woodlands; breeding season mid-May-late Sept

FISHES

		Federal Status	State Status
Bluntnose shiner	*Notropis simus simus*		T

extinct; Rio Grande; main river channel, often below obstructions over substrate of sand, gravel, and silt; damming and irrigation practices presumed major factors contributing to decline

EL PASO COUNTY

FISHES

		Federal Status	State Status
Rio Grande silvery minnow	*Hybognathus amarus*	LE	E

extirpated; historically Rio Grande and Pecos River systems and canals; reintroduced in Big Bend area; pools and backwaters of medium to large streams with low or moderate gradient in mud, sand, or gravel bottom; ingests mud and bottom ooze for algae and other organic matter; probably spawns on silt substrates of quiet coves

INSECTS

		Federal Status	State Status
A Royal moth	*Sphingicampa raspa*		

woodland - hardwood; with oaks, junipers, legumes and other woody trees and shrubs; good density of legume caterpillar foodplants must be present; Prairie acacia (Acacia augustissima) is the documented caterpillar foodplant, but there could be a few other woody legumes used

A tiger beetle *Cicindela hornii*

grassland/herbaceous; burrowing in or using soil; dry areas on hillside or mesas where soil is rocky or loamy and covered with grasses, invertivore; diurnal, hibernates/aestivates, active mostly for several days after heavy rains. the life cycle probably takes two years so larvae would always be present in burrows in the soil

Barbara Ann's tiger beetle *Cicindela politula barbarannae*

limestone outcrops in arid treeless environments or in openings within less arid pine-juniper-oak communities; open limestone substrate itself is almost certainly an essential feature; roads and trails

Poling's hairstreak *Fixsenia polingi*

oak woodland with Quercus grisea as substantial component, probably also uses Q. emoryi; larvae feed on new growth of Q. grisea, adults utilize nectar from a variety of flowers including milkweed and catslaw acacia; adults fly mid May - Jun, again mid Aug - early Sept

MAMMALS

		Federal Status	State Status
Big free-tailed bat	*Nyctinomops macrotis*		

habitat data sparse but records indicate that species prefers to roost in crevices and cracks in high canyon walls, but will use buildings, as well; reproduction data sparse, gives birth to single offspring late June-early July; females gather in nursery colonies; winter habits undetermined, but may hibernate in the Trans-Pecos; opportunistic insectivore

Black bear	*Ursus americanus*	T/SA;NL	T

bottomland hardwoods and large tracts of inaccessible forested areas; due to field characteristics similar to Louisiana Black Bear (LT, T), treat all east Texas black bears as federal and state listed Threatened

Black-footed ferret	*Mustela nigripes*	LE	

extirpated; inhabited prairie dog towns in the general area

Black-tailed prairie dog *Cynomys ludovicianus*

dry, flat, short grasslands with low, relatively sparse vegetation, including areas overgrazed by cattle; live in large family groups

EL PASO COUNTY

MAMMALS

Federal Status State Status

Cave myotis bat *Myotis velifer*

colonial and cave-dwelling; also roosts in rock crevices, old buildings, carports, under bridges, and even in abandoned Cliff Swallow (Hirundo pyrrhonota) nests; roosts in clusters of up to thousands of individuals; hibernates in limestone caves of Edwards Plateau and gypsum cave of Panhandle during winter; opportunistic insectivore

Desert pocket gopher *Geomys arenarius*

cottonwood-willow association along the Rio Grande in El Paso and Hudspeth counties; live underground, but build large and conspicuous mounds; life history not well documented, but presumed to eat mostly vegetation, be active year round, and bear more than one litter per year

Fringed bat *Myotis thysanodes*

habitat variable, ranging from mountainous pine, oak, and pinyon-juniper to desert-scrub, but prefers grasslands at intermediate elevations; highly migratory species that arrives in Trans-Pecos by May to form nursery colonies; single offspring born June-July; roosts colonially in caves, mine tunnels, rock crevices, and old buildings

Gray wolf *Canis lupus* LE E

extirpated; formerly known throughout the western two-thirds of the state in forests, brushlands, or grasslands

Long-legged bat *Myotis volans*

in Texas, Trans-Pecos region; high, open woods and mountainous terrain; nursery colonies (which may contain several hundred individuals) form in summer in buildings, crevices, and hollow trees; apparently do not use caves as day roosts, but may use such sites at night; single offspring born June-July

Pale Townsend's big-eared bat *Corynorhinus townsendii pallescens*

roosts in caves, abandoned mine tunnels, and occasionally old buildings; hibernates in groups during winter; in summer months, males and females separate into solitary roosts and maternity colonies, respectively; single offspring born May-June; opportunistic insectivore

Pecos River muskrat *Ondatra zibethicus ripensis*

creeks, rivers, lakes, drainage ditches, and canals; prefer shallow, fresh water with clumps of marshy vegetation, such as cattails, bulrushes, and sedges; live in dome-shaped lodges constructed of vegetation; diet is mainly vegetation; breed year round

Western red bat *Lasiurus blossevillii*

roosts in tree foliage in riparian areas, also inhabits xeric thorn scrub and pine-oak forests; likely winter migrant to Mexico; multiple pups born mid-May - late Jun

Western small-footed bat *Myotis ciliolabrum*

mountainous regions of the Trans-Pecos, usually in wooded areas, also found in grassland and desert scrub habitats; roosts beneath slabs of rock, behind loose tree bark, and in buildings; maternity colonies often small and located in abandoned houses, barns, and other similar structures; apparently occurs in Texas only during spring and summer months; insectivorous

EL PASO COUNTY

MAMMALS

		Federal Status	State Status
Yuma myotis bat	*Myotis yumanensis*		

desert regions; most commonly found in lowland habitats near open water, where forages; roosts in caves, abandoned mine tunnels, and buildings; season of partus is May to early July; usually only one young born to each female

MOLLUSKS

		Federal Status	State Status
Franklin Mountain talus snail	*Sonorella metcalfi*		

terrestrial; bare rock, talus, scree; inhabits igneous talus most commonly of rhyolitic origin

Franklin Mountain wood snail *Ashmunella pasonis*

terrestrial; bare rock, talus, scree; talus slopes, usually of limestone, but also of rhyolite, sandstone, and siltstone, in arid mountain ranges

REPTILES

		Federal Status	State Status
Big Bend slider	*Trachemys gaigeae*		

almost exclusively aquatic, sliders (Trachemys spp.) prefer quiet bodies of fresh water with muddy bottoms and abundant aquatic vegetation, which is their main food source; will bask on logs, rocks or banks of water bodies; breeding March-July

Chihuahuan Desert lyre snake	*Trimorphodon vilkinsonii*		T

mostly crevice-dwelling in predominantly limestone-surfaced desert northwest of the Rio Grande from Big Bend to the Franklin Mountains, especially in areas with jumbled boulders and rock faults/fissures; secretive; egg-bearing; eats mostly lizards

Mountain short-horned lizard	*Phrynosoma hernandesi*		T

diurnal, usually in open, shrubby, or openly wooded areas with sparse vegetation at ground level; soil may vary from rocky to sandy; burrows into soil or occupies rodent burrow when inactive; eats ants, spiders, snails, sowbugs, and other invertebrates; inactive during cold weather; breeds March-September

New Mexico garter snake *Thamnophis sirtalis dorsalis*

nearly any type of wet or moist habitat; irrigation ditches, and riparian-corridor farmlands, less often in running water; home range about 2 acres; active year round in warm weather, both diurnal and nocturnal, more nocturnal during hot weather; bears litter July-August

Texas horned lizard	*Phrynosoma cornutum*		T

open, arid and semi-arid regions with sparse vegetation, including grass, cactus, scattered brush or scrubby trees; soil may vary in texture from sandy to rocky; burrows into soil, enters rodent burrows, or hides under rock when inactive; breeds March-September

EL PASO COUNTY

PLANTS

Federal Status State Status

Comal snakewood *Colubrina stricta*

in El Paso County, found in a patch of thorny shrubs in colluvial deposits and sandy soils at the base of an igneous rock outcrop; the historic Comal County record does not describe the habitat; in Mexico ,found in shrublands on calcareous, gravelly, clay soils with woody associates; flowering late spring or early summer

Desert night-blooming cereus *Peniocereus greggii var greggii*

Chihuahuan Desert shrublands or shrub invaded grasslands in alluvial or gravelly soils at lower elevations, 1200-1500 m (3900-4900 ft), on slopes, benches, arroyos, flats, and washes; flowering synchronized over a few nights in early May to late June when almost all mature plants bloom, flowers last only one day and open just after dark, may flower as early as April

Hueco rock-daisy *Perityle huecoensis*

north-facing or otherwise mostly shaded limestone cliff faces within relatively mesic canyon system; flowering spring-fall

Sand prickly-pear *Opuntia arenaria*

deep, loose or semi-stabilized sands in sparsely vegetated dune or sandhill areas, or sandy floodplains in arroyos; flowering May-June

Sand sacahuista *Nolina arenicola*

Texas endemic; mesquite-sand sage shrublands on windblown Quarternary reddish sand in dune areas; flowering time uncertain May-June, June-September

Sneed's pincushion cactus *Escobaria sneedii var sneedii* LE E

xeric limestone outcrops on rocky, usually steep slopes in desert mountains, in the Chihuahuan Desert succulent shrublands or grasslands; flowering April-September (peak usually in April, sometimes opportunistically after summer rains; fruiting August - November

Texas false saltgrass *Allolepis texana*

sandy to silty soils of valley bottoms and river floodplains, not generally on alkaline or saline sites; flowering (May-) July-October depending on rainfall

Wheeler's spurge *Chamaesyce geyeri var wheeleriana*

sparingly vegetated, loose eolian quartz sand on reddish sand dunes or coppice mounds; flowering and fruiting at least August-September, probably earlier and later, as well

Notes for
County Lists of Texas' Special Species

The Texas Parks and Wildlife (TPWD) county lists **include**:

Vertebrates, Invertebrates, and Vascular Plants identified as being of conservation concern by TPWD within Texas. These special species lists are comprised of species, subspecies, and varieties that are federally listed; proposed to be federally listed; have federal candidate status; are state listed; or carry a global conservation status indicating a species is critically imperiled, very rare, vulnerable to extirpation, or uncommon.

The TPWD county lists **do not include**:

Natural Plant Communities such as Little Bluestem-Indiangrass Series (native prairie remnant), Water Oak-Willow Oak Series (bottomland hardwood community), Saltgrass-Cordgrass Series (salt or brackish marsh), Sphagnum-Beakrush Series (seepage bog).

Other Significant Features such as bird rookeries, migratory songbird fallout areas, comprehensive migratory bird information, bat roosts, bat caves, invertebrate caves, and prairie dog towns.

These lists are not all inclusive for all rare species distributions. The lists were compiled, developed, and are updated based on field guides, staff expertise, scientific publications, and the TPWD Texas Natural Diversity Database (TXNDD) (formerly the Biological and Conservation Data System) occurrence data. Historic ranges for some state extirpated species, full historic distributions for some extant species, accidentals and irregularly appearing species, and portions of migratory routes for particular species are not necessarily included. Species that appear on county lists do not all share the same probability of occurrence within a county. Some species are migrants or wintering residents only. Additionally, a few species may be historic or considered extirpated within a county.

TPWD includes the Federal listing status for your convenience and makes every attempt to keep the information current and correct. However, the US Fish and Wildlife Service (FWS) is the responsible authority for Federal listing status. The TPWD lists do not substitute for contact with the FWS and federally listed species county ranges may vary from the FWS county level species lists because of the inexact nature of range map development and use.

Status Key:

LE, LT -	Federally Listed Endangered/Threatened
PE, PT -	Federally Proposed Endangered/Threatened
SAE, SAT -	Federally Listed Endangered/Threatened by Similarity of Appearance
C -	Federal Candidate for Listing; formerly Category 1 Candidate
DL, PDL -	Federally Delisted/Proposed for Delisting
NL -	Not Federally Listed
E, T -	State Listed Endangered/Threatened
NT -	Not tracked or no longer tracked by the State
"blank" -	Rare, but with no regulatory listing status

This information is specifically for your assistance only; due to continuing data updates, **please do not redistribute the lists**, instead refer all requesters to the web site at: http://www.tpwd.state.tx.us/landwater/land/maps/gis/ris/endangered_species/ or to our office for the most current information available. For questions regarding county lists, please call (512) 389-4571.

SAIC

January 11, 2012

Texas Parks and Wildlife Department
Wildlife Division Wildlife Habitat Assessment Program
4200 Smith School Road
Austin, Texas 78744

Subject: **Threatened and Endangered Species Assessment**
McCombs Municipal Solid Waste Landfill, El Paso, Texas

Dear Wildlife Division:

The McCombs Municipal Solid Waste Landfill (Landfill) located in El Paso, Texas (City) is proposing a vertical expansion of the existing Landfill footprint to provide additional capacity. The Landfill is located in El Paso County within the El Paso city limits and serves the waste needs of the City and the surrounding area. The Landfill is an existing Type 1 MSW disposal facility owned and operated by the City. The Landfill is located at the northeast corner of the intersection of McCombs Road and Stan Roberts Road (FM 2529) in El Paso, Texas. The address of the Landfill is 13660 McCombs Road.

The proposed vertical expansion will increase the height of the Landfill from the currently permitted elevation of 4,125 feet mean sea level (MSL) to 4,305 feet MSL. The existing permitted boundary of the Landfill is currently 327 acres (permitted in 1984), and is not proposed to increase. The primary use for this facility will remain dedicated for disposal of municipal solid waste.

A letter dated August 13, 1982 from the United States Fish and Wildlife Service (USFWS) has been included in Attachment 1. According to the USFWS letter, the American Peregrine Falcon may use the project site as a feeding area or pass through the area during migration. According to the information provided on the USFWS website, the American Peregrine Falcon was delisted from the federal endangered species list on August 25, 1999. However, the American Peregrine Falcon remains a State of Texas protected species.

As indicated in the USFWS letter, it is unlikely that the Landfill will have any effect on this species. However, if the American Peregrine Falcon were to be observed within the permitted Landfill area, the employees will be instructed to follow the steps listed below:

1. Avoid contact with the bird;
2. Temporarily halt or move site operations to an area away from the bird's location to prevent disrupting the bird's activities while feeding or passing by the site;

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

3. Wait until the bird abandons the site on its own will; and
4. Resume normal site operations once the bird has taken flight.

In addition, Landfill personnel will be trained regarding the bird's physical characteristics and appearance in order to be able to identify it at once and with certainty during operations. This training will prevent unnecessary and unwarranted disruptions of site activities due to the presence of birds that may look similar to the American Peregrine Falcon.

We are requesting information regarding any listed threatened or endangered species or their critical habitat within range of the project site. This information is required by Texas Administrative Code Chapter 330 (30 TAC §330.61 (n)).

If you have any questions or require additional information, please contact me at 651-994-8415 or fredric.j.doran@saic.com.

Sincerely,

SAIC Energy, Environment & Infrastructure, LLC

According to the USFWS letter, the American Peregrine Falcon may use the project site as a feeding area or pass through the area during migration. According to the information provided on the USFWS website, the American Peregrine Falcon was delisted from the federal endangered species list on August 25, 1999. However, the American Peregrine Falcon remains a State of Texas protected species.

As indicated in the USFWS letter, it is unlikely that the Landfill will have any effect on this species. However, if the American Peregrine Falcon were to be observed within the permitted Landfill area, the employees will be instructed to follow the steps listed below:

1. Avoid contact with the bird; 31.982554 -106.408597
2. Temporarily halt or move site operations to an area away from the bird's location to prevent disrupting the bird's activities while feeding or passing by the site;

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

3. Wait until the bird abandons the site on its own will; and
4. Resume normal site operations once the bird has taken flight.

In addition, Landfill personnel will be trained regarding the bird's physical characteristics and appearance in order to be able to identify it at once and with certainty during operations. This training will prevent unnecessary and unwarranted disruptions of site activities due to the presence of birds that may look similar to the American Peregrine Falcon.

We are requesting information regarding any federally listed threatened or endangered species or their critical habitat within range of the project site. This information is required by Texas Administrative Code Chapter 330 (30 TAC §330.61 (n)).

If you have any questions or require additional information, please contact me at 651-994-8415 or fredric.j.doran@saic.com.

Sincerely,

SAIC Energy, Environment & Infrastructure, LLC

#2 Civic Center Plaza - 5th Floor
El Paso, Texas 79999

Dear Ms. Staley:

By letter dated August 4, 1982, you provided the U.S. Fish and Wildlife Service (FWS) with maps showing the location of a proposed sanitary landfill at the intersection of McCombs Road and FM 2529 and requested information concerning endangered species. The proposed landfill would generally utilize an abandoned quarry adjacent to an existing landfill.

Federally listed endangered species present in El Paso County are the American peregrine falcon (Falco peregrinus anatum) and Sneed pincushion cactus (Coryphantha sneedii var. sneedii). It is unlikely that expanding the sanitary landfill would have any effect on the above listed species because the cactus is confined to the Franklin Mountains as is the nesting habitat of the peregrine falcon. The peregrine may use the project site as a feeding area or pass through the area during migration.

The letter describing the site contained insufficient information to assess the effect leaching from the landfill would have on ground water quality. The bottom of the abandoned quarry may need to be sealed to prevent contamination of ground water resources. If this is not a problem, the FWS believes that the proposed landfill site is a good location for expanding the City's waste disposal capability.

We appreciate the opportunity to review your project. If we may be of further assistance please, contact Don A. Meineke or me (Telephone 512/888-3346).

Sincerely yours,

ROGELIO PEREZ
Field Supervisor

50 CFR Part 17

Endangered and Threatened Wildlife and Plants; Final Rule To Remove the American Peregrine Falcon From the Federal List of Endangered and Threatened Wildlife, and To Remove the Similarity of Appearance Provision for Free-Flying Peregrines in the Conterminous United States; Final Rule

DEPARTMENT OF THE INTERIOR

Fish and Wildlife Service

50 CFR Part 17

RIN 1018–AF04

Endangered and Threatened Wildlife and Plants; Final Rule To Remove the American Peregrine Falcon From the Federal List of Endangered and Threatened Wildlife, and To Remove the Similarity of Appearance Provision for Free-Flying Peregrines in the Conterminous United States

AGENCY: Fish and Wildlife Service, Interior.

ACTION: Final rule.

SUMMARY: We, the U.S. Fish and Wildlife Service (Service), have determined that the American peregrine falcon (*Falco peregrinus anatum*) is no longer an endangered or threatened species pursuant to the Endangered Species Act of 1973, as amended (Act). This determination is based on available data indicating that this subspecies has recovered following restrictions on organochlorine pesticides in the United States and Canada, and following the implementation of successful management activities. This action will remove the American peregrine falcon (*Falco peregrinus anatum*) throughout its range as an endangered species from the Federal List of Endangered and Threatened Wildlife, thereby removing all protections provided by the Act. It also will remove the designation of ''endangered due to similarity of appearance'' for any free-flying peregrine falcons within the 48 conterminous United States. It will not affect protection provided to this species by the Migratory Bird Treaty Act (MBTA), the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES), or state laws and regulations, nor will it affect the endangered listing status of the Eurasian peregrine falcon (*Falco peregrinus peregrinus*) under the Act.

EFFECTIVE DATE: August 25, 1999.

ADDRESSES: The administrative file for this rule is available for inspection, by appointment, during normal business hours at the U.S. Fish and Wildlife Service, Ventura Fish and Wildlife Office, 2493 Portola Road, Suite B, Ventura, California 93003 (telephone (805) 644–1766/facsimile 805/644–3958).

FOR FURTHER INFORMATION CONTACT: Robert Mesta at the above address for further information on the removal of the peregrine falcon from the endangered species list.

SUPPLEMENTARY INFORMATION:

Background

The peregrine falcon (*Falco peregrinus*) is a medium-sized raptor weighing approximately 1,000 grams (36 ounces) and having a wing span of 112 centimeters (44 inches). The adult peregrine falcon has a dark gray back and crown, dark bars or streaks on a pale chest and abdomen, and heavy malar (cheek) stripes on the face. Immature falcons are buff-colored in front and have dark brown backs; adults are white or buff in front and bluish-gray on their backs. Peregrines prey almost entirely on other birds, and occasionally on bats, caught in midair (Hickey and Anderson 1969).

The peregrine falcon has an almost worldwide distribution, with three subspecies recognized in North America (Brown and Amadon 1968). The Peale's falcon (*F. p. pealei*) is a year-round resident of the northwest Pacific coast from northern Washington through British Columbia to the Aleutian Islands. The Arctic peregrine falcon (*F. p. tundrius*) nests in the tundra of Alaska, Canada, and Greenland, and is typically a long-distance migrant, wintering as far south as South America. The American peregrine falcon (*F. p. anatum*) occurs throughout much of North America from the subarctic boreal forests of Alaska and Canada south to Mexico. The American peregrine falcon nests from central Alaska, central Yukon Territory, and northern Alberta and Saskatchewan, east to the Maritimes and south (excluding coastal areas north of the Columbia River in Washington and British Columbia) throughout western Canada and the United States to Baja California, Sonora, and the highlands of central Mexico (48 FR 8799). American peregrine falcons that nest in subarctic areas generally winter in South America, while those that nest at lower latitudes exhibit variable migratory behavior; some are nonmigratory (Yates *et al.* 1988).

Since the early 1970s, efforts to reestablish peregrine falcons in the eastern and midwestern United States have successfully returned this species to areas from which it was extirpated (See ''Eastern United States'' under ''Peregrine Falcon Recovery''). Peregrine falcons are now found nesting in all States within their historical range east of the 100th meridian, except for Rhode Island, West Virginia, and Arkansas.

Peregrine falcons declined precipitously in North America following World War II (Kiff 1988). Research implicated organochlorine pesticides, mainly 1,1,1-trichloro-2,2-bis(p-chlorophenyl)-ethane (DDT), applied in the United States and Canada during this same period, as causing the decline (for a review, see Risebrough and Peakall 1988). Use of these chemicals peaked in the 1950s and early 1960s and continued through the early 1970s. Organochlorines and their metabolites, including DDT and its principal metabolite DDE (1,1-dichloro-2,2-bis(*p*-chlorophenyl)-ethylene), aldrin, dieldrin, and others, are stable, persistent compounds that are stored in the fatty tissues of animals ingesting contaminated food (Fyfe *et al.* 1988).

Organochlorines can affect peregrine falcons either by causing direct mortality or by adversely affecting reproduction. Because mortality in wild birds is difficult to study, the effect of organochlorines on mortality is not as well known as the effects on reproduction. Organochlorines can adversely affect reproduction by causing egg breakage, addling, hatching failure, and abnormal reproductive behavior by the parent birds (Risebrough and Peakall 1988). DDE prevents normal calcium deposition during eggshell formation, resulting in thin-shelled eggs that are susceptible to breakage during incubation. In general, populations laying eggs with shells that averaged more than 17 percent thinner than pre-DDT eggs had such high rates of reproductive failure that the number of peregrine falcon pairs declined (Peakall and Kiff 1988).

During the period of DDT use in North America, eggshell thinning and nesting failures were widespread in peregrine falcons, and in some areas, successful reproduction virtually ceased (Hickey and Anderson 1969). As a result, there was a slow but drastic decline in the number of peregrine falcons in many areas of North America. The degree of exposure to these pesticides varied among regions, and peregrine falcon numbers in more contaminated areas suffered greater declines. Peregrine falcons that nested outside of agricultural and forested areas where DDT was heavily used were affected less, although some of these individuals were still exposed to DDT when wintering in areas of pesticide use. Presumably all peregrine falcon individuals have eaten some migratory prey containing organochlorines (for reviews, see Hickey and Anderson 1969; Kiff 1988; Peakall and Kiff 1988).

Peregrine falcons nesting in the agricultural and forested areas east of the Mississippi River in the United States and in eastern Canada south of the boreal forest were the most heavily contaminated and were essentially

extirpated by the mid-1960s (Berger *et al.* 1969). Peregrine falcons in the Great Plains states east of the Rocky Mountains and south of the boreal forest in Canada and the United States were also extirpated in the DDT-era (Cade 1975; Enderson *et al.* 1995). No active eyries (nests) were found in surveys of 133 formerly used peregrine falcon eyries in the latter part of the 1964 nesting season in the eastern United States and the Maritime Provinces in Canada (Berger *et al.* 1969). By 1975, there were only three peregrine falcon pairs in Alberta, and no other peregrine falcon pairs were found south of latitude 60 degrees North and east of the Rocky Mountains in Canada (Erickson *et al.* 1988).

West of the 100th meridian, peregrine falcons were significantly reduced; only 33 percent of historical nest sites in the Rocky Mountains were still occupied by 1965 (Enderson 1969). The peregrine falcon disappeared as a breeding species from southern California, and major declines also occurred in other parts of the western United States and in much of southern Canada and the Northwest Territories (Kiff 1988). In contrast, peregrine falcons in most areas of the Pacific coast of Alaska remained fairly stable during this period, due to their lower exposure to organochlorine pesticides. The exact degree of local declines in much of western North America remains somewhat speculative due to a lack of accurate pre-pesticide era census data. For example, in the southwestern United States and mainland Mexico, peregrine falcons were not censused until after the beginning of the use of organochlorines (Kiff 1988).

Previous Federal Actions

Population declines due to negative impacts of DDT and its metabolites on peregrine falcon reproduction and survival led us to list two of the three North American subspecies, the Arctic peregrine falcon and the American peregrine falcon, as endangered in 1970 under the Endangered Species Conservation Act of 1969 (Public Law 91–135, 83 Stat. 275). Arctic and American peregrine falcons were included in the United States' list of endangered foreign species on June 2, 1970 (35 FR 8491) under the Endangered Species Conservation Act of 1969, and the native list of endangered species on October 13, 1970 (35 FR 16047). Upon passage of the Endangered Species Act of 1973, as amended (Act) (16 U.S.C. 1531 *et seq.*), the native and foreign species lists were combined into a single list of endangered and threatened species. Both the American and Arctic peregrine falcon subspecies were listed as endangered throughout their respective ranges. The Peale's peregrine falcon was not listed because it was reproducing at near normal levels with only traces of DDT.

On March 1, 1983, we published a proposed rule to (1) reclassify the Arctic peregrine falcon from endangered to threatened; (2) clarify the status of the American peregrine falcon (*Falco peregrinus anatum*) in some areas of its range; and (3) designate all free-flying peregrine falcons in the 48 conterminous United States as endangered under the similarity of appearance provisions of section 4(e) of the Act (48 FR 8796). A final rule was published on March 20, 1984 (49 FR 10520). Pursuant to the similarity of appearance provisions, species that are not considered to be endangered or threatened are treated as such for the purpose of providing protection to a species that is biologically endangered or threatened.

On June 12, 1991, we announced in the **Federal Register** a Notice of Status Review of American and Arctic peregrines (56 FR 26969). The Arctic peregrine was removed as a threatened species from the Federal List of Endangered and Threatened Wildlife on October 5, 1994 (59 FR 50796) but was still regulated under the Act in the lower 48 United States due to the similarity of appearance provision for all *Falco peregrinus* peregrine falcons. The similarity of appearance provision was maintained because the American peregrine falcon was still listed as endangered.

We published an Advanced Notice of a Proposal to Remove the American Peregrine Falcon from the Federal List of Endangered and Threatened Wildlife on June 30, 1995 (60 FR 34406). This was based on data indicating this subspecies was recovered following restrictions on the use of organochlorine pesticides in the United States and Canada and because of successful management activities, including the reintroduction of captive-bred and relocated wild hatchling peregrine falcons. Current data provides additional support for recovery of all North American peregrine falcons, including the American peregrine falcon subspecies. We published a proposed rule to remove the peregrine falcon in North America from the Federal List of Endangered and Threatened Wildlife on August 26, 1998, based on continuing data indicating this species was recovered (63 FR 45446).

The processing of this final rule conforms with our listing priority guidance published on May 8, 1998 (63 FR 25502). This guidance clarifies the order in which we will process rulemakings, giving highest priority to handling emergency situations (Tier 1) and second highest priority (Tier 2) to resolving the listing status of outstanding proposed listings, resolving the conservation status of candidate species, processing administrative findings on petitions to add species to the lists or reclassify species from threatened to endangered status, and delisting or reclassifying actions. The lowest priority actions, processing critical habitat designations, are in Tier 3. Processing of this final rule is a Tier 2 action.

Peregrine Falcon Recovery

Section 4(f) of the Act directs us to develop and implement recovery plans for listed species. In some cases, we appoint experts to recovery teams to assist in the writing of recovery plans. Between 1974 and 1975 we formed recovery teams consisting of Service, State, and other experts. In cooperation with us, these recovery teams produced four regional recovery plans: three for the American peregrine falcon (Alaska, Rocky Mountains/Southwest United States, and the Pacific Coast of the United States), and one for the peregrine falcon in the eastern United States. Although no United States recovery plans established recovery criteria for peregrine falcons nesting outside of the United States, the Canadian Wildlife Service published an *Anatum* Peregrine Falcon Recovery Plan (Erickson *et al.* 1988) establishing recovery criteria for American peregrine falcons in Canada. Recovery plans for peregrine falcons called for captive rearing and release of birds in several areas of North America. In the eastern United States, where peregrine falcons were extirpated, the initial recovery objective was to reestablish peregrine falcons through the release of offspring from a variety of wild stocks being held in captivity by falconers. The first experimental releases of captive-produced young occurred in 1974 and 1975 in the United States. Since then, approximately 6,000 falcons were released throughout its historic range in North America. These releases helped to re-establish breeding pairs in areas where the species was extirpated, and accelerated the recovery of the species.

Later, reintroduction was also pursued in eastern Canada using only *F. p. anatum* breeding stock from the boreal regions of the subspecies' range. All peregrine falcons released to augment wild populations in western North America west of the 100th meridian, where small numbers of

American peregrines survived the pesticide era, were derived from western *anatum* stock (Enderson *et al.* 1995).

The most significant factor in the recovery of the peregrine falcon was the restriction placed on the use of organochlorine pesticides. Use of DDT was banned in Canada in 1970 and in the United States in 1972 (37 FR 13369). Restrictions that controlled the use of aldrin and dieldrin were imposed in the United States in 1974 (39 FR 37246). Since implementation of these restrictions, residues of the pesticides have significantly decreased in many regions where they were formerly used. Consequently, reproductive rates in most surviving peregrine falcon populations in North America improved, and numbers began to increase (Kiff 1988; Enderson *et al.* 1995).

In Alaska and northwest Canada, American peregrine falcon populations were locally depressed, but enough individuals survived the pesticide era to allow populations to expand without the need for release of captive-bred falcons. Likewise, in the southwestern United States, very few captive-bred birds were released, and populations recovered naturally following restrictions on the use of organochlorine pesticides. In southwest Canada, the northern Rocky Mountain States, and the Pacific Coast States, however, local populations were greatly depressed or extirpated, and over 3,400 young American peregrine falcons were released to promote recovery in those areas (Enderson *et al.* 1995).

American peregrine falcon population growth was noted in Alaska in the late 1970s (Ambrose *et al.* 1988b), and, by 1980, population growth was found in many other areas (Enderson *et al.* 1995). The rate of increase varied among regions of North America, undoubtedly influenced by variation in patterns of pesticide use, potential differences in the rate of pesticide degradation, and the degree to which local populations had declined. Populations in some portions of the range of American peregrine falcons, such as Alaska, northwest Canada, and southwestern United States, reached densities several years ago that suggested recovery was approaching completion (Ambrose *et al.* 1988b; Mossop 1988; Geoff Holroyd, Canadian Wildlife Service, *in litt.* 1993; Enderson *et al.* 1995). Residual organochlorine pesticide contamination continues to affect eggshells in some areas, such as portions of coastal California (Jarman 1994) and western Texas (Bonnie McKinney, Texas Parks and Wildlife Department, pers. comm. 1997), but these effects are localized. Despite these localized effects and the variation in the rate of increase among regions, local populations throughout North America have increased in size, and positive trends in nearly all areas suggest that an extensive recovery of American peregrine falcons has taken place.

Recovery Status

To aid in assessing peregrine falcon recovery, the current status was compared to specific recovery plan objectives for American peregrine falcons in (1) Alaska, (2) Canada, (3) the Pacific Coast, (4) the Rocky Mountains and the Southwest, and for the peregrine falcon in, and (5) the eastern United States. The current status of the subspecies in Mexico is discussed below, although no recovery plan or recovery objectives are established for Mexico.

Alaska

The Peregrine Falcon Recovery Plan, Alaska Population (Alaska Recovery Plan) (U.S. Fish and Wildlife Service 1982a) includes both Arctic and American peregrine falcons nesting in Alaska. The following discussion relates only to provisions regarding the American peregrine falcon, as the Arctic peregrine falcon was delisted on October 5, 1994 (59 FR 50796).

The Alaska Recovery Plan established recovery objectives based on four measurements for assessing the status of American peregrine falcons including population size, reproductive performance, pesticide residues in eggs, and eggshell thickness. The recovery objectives included:

(1) 28 nesting pairs in 2 specified study areas (16 in upper Yukon and 12 in upper Tanana);

(2) An average of 1.8 young per territorial pair;

(3) Average organochlorine concentration in eggs of less than 5 parts per million (ppm) (wet weight basis DDE); and

(4) Eggshells no more than 10 percent thinner than pre-DDT era eggshells.

The Alaska Recovery Plan suggested that these objectives be maintained in the specified study areas for 5 years before reclassifying from endangered to threatened status, and remain constant or improve for an additional 5 years before delisting.

Surveys were conducted in the upper Yukon and Tanana Rivers, for which historical population data were available, using consistent methodology from 1973 to the present so trends would be discernable. Surveys conducted between 1966 and 1998 along the upper Yukon River demonstrated increases in the number of occupied nesting territories from a low of 11 known pairs in 1973 to 46 pairs in 1998 (Ambrose *et al.* 1988b; Robert Ambrose, U.S. Fish and Wildlife Service, *in litt.* 1997a, 1999). Similarly, along the upper Tanana River, the number of occupied nesting territories increased from 2 in 1975 to 33 in 1998 (R. Ambrose, *in litt.* 1997a; 1999). The recovery objective of 28 occupied nesting territories in the two study areas was first achieved (post-DDT) in 1988, with 23 nesting territories on the Yukon River and 12 on the Tanana River. The number has increased steadily since that time to the current level of 79 occupied nesting territories in 1998, with 46 pairs on the Yukon River and 33 pairs on the Tanana River (R. Ambrose, *in litt.* 1999). Thus, the recovery objective of 28 occupied nesting territories was achieved and surpassed for 10 years. A minimum of 301 breeding pairs of American peregrine falcons currently nest in Alaska.

Productivity measured along the upper Yukon and Tanana Rivers fell to a low of about 1.0 young per territorial pair per year (yg/pr) in the late 1960s, but began to increase in the mid-1970s. By 1982, productivity exceeded the objective of 1.8 yg/pr, and varied between 1.6 and 3.0 yg/pr in the years since. Between 1994 and 1998, productivity averaged 2.0 yg/pr (sample size (N) = 362 nests/pairs). Overall, between 1982 and 1998, the Yukon River study area averaged 1.79 yg/pr, and the Tanana River study area averaged 1.85 yg/pr (R. Ambrose, *in litt.* 1999). It is expected that there are yearly variations in productivity, which most wildlife species experience. However, average productivity for the peregrine falcon was constant or improving, thus meeting the goal of at least 1.8 yg/pr over the last 10 years as recommended by the Alaska Recovery Plan.

Mean concentrations of DDE in peregrine falcon eggs in excess of 15–20 ppm are associated with nesting failure, whereas productivity is usually sufficient to maintain population size if residues average less than this concentration (Peakall *et al.* 1975, as cited in Peakall and Kiff 1988; Newton *et al.* 1989). In Alaska, average DDE residues in American peregrine falcons averaged 12.2 ppm from 1979 through 1984, 5.8 ppm from 1988 through 1991, and 3.5 ppm from 1993 through 1995 (R. Ambrose, *in litt.* 1997b). Current data suggest that the concentrations of less than 5 ppm DDE residue levels in peregrine falcon eggs have improved in the last 10 years (R. Ambrose *in litt.* 1997b). As a result of lowered DDE

concentrations, there was consistent population growth during that time.

In Alaska, eggshells were as much as 20–22 percent thinner than pre-DDT era shells in the mid-1960s (Cade *et al.* 1988). By the early 1980s, shells were about 14 percent thinner than before the DDT era (Ambrose *et al.* 1988a). Eggshells averaged 13.0 percent thinner from 1979 through 1984, 13.1 percent thinner from 1988 through 1991, and 12.1 percent thinner from 1993 through 1995 (R. Ambrose, *in litt.* 1997b). The average thickness of pre-DDT American peregrine falcon eggs from Alaska is not precisely known, so current estimates of thinning could be inaccurate. While average eggshell thinning has not yet reached the level of 10 percent or less of the pre-DDT era, it has improved over the last 10 years. Also, reproduction was sufficient to allow consistent population growth since the late 1970s, and productivity has, on average, exceeded its stated recovery objective for 17 years.

In summary, based on the most current information (1998 survey and early 1990s contamination data), we conclude that goals underlying all four objectives were met or exceeded. On average, the number of pairs occupying nesting territories in the two study areas and productivity exceeded the recovery objectives for the past 17 years. Neither DDE residues in eggs nor eggshell thinning has prevented a dramatic population growth since the late 1970s.

Canada

The 1988 *Anatum* Peregrine Falcon Recovery Plan for Canada (Canadian Recovery Plan) (Erickson *et al.* 1988) categorized the historical range of the American peregrine falcon throughout Canada into three regions, which include the Western Mountains, Interior Plains, and the Eastern Seaboard and Great Lakes. These regions were subdivided into nine zones on the basis of historical population levels, habitat, political boundaries, and restoration needs. The zones are (1) Maritime, (2) Great Lakes, (3) Prairies, (4) Mackenzie River Valley, (5) Northern Mountains, (6) Southern Mountains, (7) Eastern Mackenzie Watershed, (8) Western Canadian Shield, and the (9) Eastern Canadian Shield. Coastal British Columbia was excluded from consideration in the Canadian Recovery Plan because that area is occupied by *F.p. pealei.*

The goal of the Canadian Recovery Plan was to increase the wild American peregrine falcon population in Canada so the subspecies is no longer considered endangered or threatened by the Committee on the Status of Endangered Wildlife in Canada. The proposed objectives were (1) to establish by 1992 a minimum of 10 territorial American peregrine falcon pairs in each of Zones 1 to 6, and (2) to establish by 1997, in each of 5 of these 6 zones, a minimum of 10 pairs naturally fledging 15 (1.5 yg/pr) or more young annually, measured as a 5-year average beginning in 1993. No recovery objectives were established for Zones 7, 8, and 9. The Canadian Recovery Plan did not contain separate objectives for reclassification of the subspecies in Canada from its current endangered status to threatened.

Starting in 1990, the Canadian Wildlife Service has coordinated and published a national range-wide peregrine falcon population survey once every 5 years. The results of the 1995 national population survey were used in the following status summary of the American peregrine falcon in Canada (Ursula Banasch, Canadian Wildlife Service, *in litt.* 1997).

There were 98 known nest sites in Zones 1 and 2 (southern Ontario and Quebec, northern Great Lakes, Bay of Fundy and Labrador), and surveys located 64 pairs. There were 98 known nest sites in Zone 3 (Manitoba, Saskatchewan and Alberta), and surveys located 41 pairs. There were 117 known nest sites in Zone 4 (eastern N.W. Territories), and surveys located 83 pairs. There were 125 known nest sites in Zone 5 (Yukon), and surveys located 113 pairs. There were 50 known nest sites in Zone 6 (Interior British Columbia), and surveys located 18 pairs. The total known number of pairs for all six zones in 1995 was 319, with minimum objectives achieved for every recovery zone.

The only comprehensive range-wide productivity surveys available to us were the national population surveys coordinated by the Canadian Wildlife Service in 1990 and 1995 (U. Banasch, *in litt.* 1997; Holroyd and Banasch 1996). Surveys conducted in the intervening years were not nationally coordinated, and therefore not complete. Thus, we used the combined average annual productivity data collected in the 1990 and 1995 surveys to address this recovery objective.

In Zones 1 and 2, average productivity was 1.7 yg/pr (N=104 nests). In Zone 3, average productivity was 1.5 yg/pr (N=55). In Zone 4, average productivity was 2.0 yg/pr (N=171). In Zone 5, average productivity was 1.8 yg/pr (N=626). No productivity data were available for Zone 6. The 2-year average annual productivity for the Canadian population of American peregrine falcons was 1.8 yg/pr.

Although the Canadian Recovery Plan did not identify recovery objectives for pesticide residue or eggshell thinning levels, 205 eggs and 62 samples from 28 specimens of peregrine falcons were collected in Canada between 1965 and 1987 to assess organochlorine residue concentrations. In all three subspecies (*F.p. anatum, F.p. tundrius, F.p. pealei*), the proportion of specimens having residue concentrations above established critical values (concentration at which egg failure occurs, which varies among organochlorine contaminants) had decreased and was inversely correlated with improvements in the reproductive success of the population (Peakall *et al.* 1990).

In summary, the Canadian Recovery Plan identified two objectives to determine recovery for the American peregrine falcon population in Canada. Based on current available information, both objectives were met. The total number of pairs for all six zones in 1995 was 319, with minimum objectives achieved for every recovery zone. This count exceeds the total recovery objective of 60 pairs by 259 pairs. The average annual productivity data for 1990 and 1995 either met or exceeded objectives in five of the six zones with an average annual productivity of 1.8 yg/pr for the American peregrine falcon population in Canada.

Pacific Coast

To reclassify the American peregrine falcon from endangered to threatened, the Pacific Coast Recovery Plan (Pacific Population Plan) (U.S. Fish and Wildlife Service 1982b) recommended that 122 pairs be established in a specified distribution spanning California, Washington, Oregon, and Nevada. The distribution goals were based on 22 management units distributed throughout the historic range of the Pacific Coast peregrine falcon population. For each management unit, the population must achieve a specified minimum number of active pairs before downlisting can be considered. The Pacific Population Plan also recommended that with attainment of 185 wild, self-sustaining pairs (California 120, Oregon 30, Washington 30, and Nevada 5 pairs) and an average productivity of 1.5 yg/pr for a 5-year period, the subspecies could be considered for delisting. Since this final rule addresses the delisting of the peregrine falcon, only the latter two objectives are discussed in this section. The Pacific Population Plan defined a ''self-sustaining'' population as one whose natural productivity without human management is equal to or greater than its mortality.

By 1976, no American peregrine falcons were found at 14 historical nest sites in Washington, and Oregon had also lost most of its peregrine falcons. In addition, only 1 or 2 pairs remained on the California coast, with no more than 10 nest sites known to be occupied in the entire State (Cade 1994). A steadily increasing number of American peregrine falcon pairs breeding in Washington, Oregon, and Nevada was indicated by surveys from 1991 through 1998. Known pairs in Washington increased from 17 to 45, in Oregon from 23 to 51, and in Nevada from 3 to 6 (Gary Herron, Nevada Division of Wildlife, pers. comm. 1997; Martin Nugent, Oregon Department of Fish and Wildlife, *in litt.* 1999; David Anderson, Washington Department of Fish and Game, *in litt.* 1997). The number of American peregrine falcons in California increased from an estimated low of 5 to 10 breeding pairs in the early 1970s (Herman 1971), to a minimum of 167 occupied sites in 1998 (Janet Linthicum, Santa Cruz Predatory Bird Research Group, *in litt.* 1999). The increase in California was concurrent with the restriction of DDT and management that included the release of over 750 American peregrine falcons, including captive-reared and relocated wild hatchlings, through 1997 (Walton 1997). Recovery of American peregrine falcons in some areas of California, however, was impeded by continuing elevated DDT levels (Jarman 1994; Walton 1997).

The recovery of the peregrine falcon could be the result of a lower than expected first-year mortality of released birds from the augmentation program, which accelerated the growth of the Pacific population (Brian Walton, Santa Cruz Predatory Bird Research Group, pers. comm. 1997). As a result, intensive human management has essentially ended, and the release of captive-bred American peregrine falcons was suspended in Nevada in 1989, in California in 1992 (although the relocation of wild hatchlings continues), and in Oregon and Washington in 1995. Based on available information, the first recovery objective was met; a minimum known population of 270 pairs exceeds the delisting goal of 185 by 85 pairs. Also, the distribution goals for the Pacific Coast population was met in all four States. Surveys conducted from 1991 through 1998 demonstrate a steadily increasing number of American peregrine falcon pairs, indicating that natural productivity is greater than mortality in this recovery region.

Productivity measured in Washington between 1993 and 1998 ranged from 1.3 to 1.8 yg/pr, with an average of 1.5 yg/pr (N=204) (D. Anderson, *in litt.* 1999). In Oregon, productivity between 1993 and 1998 ranged from 0.8 to 1.9 yg/pr, with an average of 1.3 yg/pr (N=178) (M. Nugent, *in litt.* 1997; David Peterson, U.S. Fish and Wildlife Service, *in litt.* 1999). Between 1993 and 1998, productivity in California ranged from 1.4 to 1.7 yg/pr (N=523), with an average of 1.6 yg/pr (J. Linthicum *in litt.* 1999). No productivity data were available for Nevada.

Productivity, an important measure of population health, can be difficult to determine in wide-ranging species nesting in remote landscapes that are often difficult to access. However, available data indicate that the average productivity from 1993 through 1998 in Washington, Oregon and California was 1.5 yg/pr (D. Anderson, *in litt.* 1999; M. Nugent, *in litt.* 1997; David Peterson, U.S. Fish and Wildlife Service, *in litt.* 1999; J. Linthicum *in litt.* 1999). Therefore, we consider this objective to be met.

The Pacific Population Plan did not identify recovery objectives for pesticide residue or eggshell thinning levels. However, organochlorine residues and eggshell thinning were measured in California starting in the early 1970s. Jarman (1994) reported DDE concentrations in 105 peregrine eggs collected from California from 1987 to 1992, and 11 eggs from Oregon from 1990 through 1993. Data collected in nine study regions in California (Jarman 1994) indicated the highest concentrations of DDE were found in California eggs from the Channel Islands and mid-coast with 21 and 13 ppm, respectively. The southern coast and San Francisco regions had the lowest concentrations of 5.5 and 4.3 ppm, respectively. The DDE concentrations in eggs collected along the coast of California (between San Francisco Bay and 34° N) did not decrease between 1969 and 1992 (Jarman 1994). Eggs from Oregon contained DDE levels of 10 ppm.

Eggshells from coastal California continued to show thinning. In northern and central coastal California, eggshells collected between 1975 and 1995 averaged 17.7 and 19.1 percent thinner than pre-DDT era, respectively (J. Linthicum, *in litt.* 1996). In northern interior California, where 104 of the 186 sites were active at least once from 1975–1993, eggshells averaged 15.6 percent thinner than pre-DDT era shells (J. Linthicum, *in litt.* 1996). Eggshells collected on the Channel Islands off the southern coast of California in 1992–1995 averaged 19.4 percent thinner than those collected in California prior to 1947 (J. Linthicum, *in litt.* 1996). In montane California, the average was 15 percent thinner than normal, and in the southern interior (coastal mountains) the average was 17.9 percent thinner than normal (J. Linthicum, *in litt.* 1996). Urban pairs experienced eggshell thinning averaging 8.7 percent in the San Francisco area and 10.9 percent in the Los Angeles/Orange County area. A summary of 633 clutch mean measurements representing 1,237 samples of one or more eggshells collected between 1975 and 1995 from the historical range of the American peregrine falcon in California averaged 16.1 percent thinner (J. Linthicum, *in litt.* 1996). However, current reproduction indicates an expanding population in most areas despite high organochlorine residue concentrations and associated eggshell thinning in some areas of the Pacific population.

Rocky Mountain/Southwest

The American Peregrine Falcon Rocky Mountain/Southwest Population Recovery Plan (U.S. Fish and Wildlife Service 1984) established three objectives for delisting, including (1) increasing the *Falco peregrinus anatum* population in the Rocky Mountain/Southwest region to a minimum of 183 breeding pairs and the following distribution: Arizona (46), Colorado (31), Idaho (17), Montana (20), Nebraska (1), New Mexico (23), North Dakota (1), South Dakota (1), Texas (8), Utah (21), and Wyoming (14); (2) sustaining a long-term average production of 1.25 yg/pr without manipulation by 1995; and (3) observing eggshell thinning of no more than 10 percent from the pre-DDT era for a 5-year span.

The prairie States of North Dakota, South Dakota, Nebraska, Kansas, and Oklahoma contain little peregrine falcon habitat, and historical data are incomplete. No recovery goals for a specific number of peregrine falcon pairs were set for Kansas or Oklahoma; nesting peregrine falcons are not known from Oklahoma. Currently, South Dakota, Nebraska and Kansas each have one peregrine falcon pair (Mark Martell, The Raptor Center, pers. comm. 1998; Tordoff *et al.* 1997); no peregrine falcon pairs are currently known to occur in North Dakota or Oklahoma.

The Rocky Mountain/Southwest population of the American peregrine falcon has made a profound comeback since the late 1970s when surveys showed no occupied nest sites in Idaho, Montana, or Wyoming and few pairs in Colorado, New Mexico, and the Colorado Plateau, including parts of southern Utah and Arizona (Cade 1994). Surveys conducted from 1991 through 1998 indicated that the number of American peregrine falcon pairs in the

Rocky Mountain/Southwest population is steadily increasing. In 1991, this population supported 367 known pairs; in 1998 the number of pairs increased to 535 (Robert Mesta, U.S. Fish and Wildlife Service, *in litt.* 1999). Surveys conducted from 1992 through 1998 showed that, with the exception of North Dakota, all States within the Rocky Mountain/Southwest population have met or exceeded their specific delisting goals for breeding pairs.

The current minimum known number of peregrine falcon pairs for each State include Arizona 159, Colorado 89, Idaho 17, Montana 18, Nebraska 1, New Mexico 32, North Dakota 0, South Dakota 1, Texas 11, Utah 164, Wyoming 42, and Kansas 1 (Greg Beatty, Arizona Game and Fish Department, *in litt.* 1997; James Enderson, Western Peregrine Falcon Recovery Team, pers. comm. 1999; Dennis Flath, Montana Department of Fish and Parks, *in litt.* 1999; Frank Howe, Utah Division of Wildlife Resources, *in litt.* 1999; Levine *et al.* 1998; McKinney 1994; B. McKinney, pers. comm. 1999; Robert Oakleaf, Wyoming Game and Fish Department, *in litt.* 1999; Sator O. Williams III, New Mexico Department of Game and Fish, *in litt.* 1999). The current Rocky Mountain/Southwest population is 535, which surpasses the objective of 183 by 352 pairs.

In Arizona , productivity from 1989 through 1997 ranged from 0.9 to 1.8 yg/yr, with an average productivity of 1.1 yg/pr (N=294). Recent average productivity (1994–1997) is 0.9 yg/pr (N=194) (Ward and Siemens 1995; G. Beatty, *in litt.* 1997).

In 1973, 1974, and 1975, productivity in Colorado was 0.2 (N=11), 1.9 (N=8), and 0.7 yg/pr (N=8), respectively, reflecting the irregular and generally poor productivity typical of the 1970s (Platt and Enderson 1988). Long term productivity measured in Colorado from 1985 through 1998 ranged from 1.2 to 1.9 yg/pr, with an average of 1.6 yg/pr (N=753) (Gerry Craig, Colorado Division of Wildlife, *in litt.* 1999; J.H. Enderson, pers. comm. 1999). Recent productivity from 1994 through 1998, averaged 1.6 yg/pr (N=395) (G. Craig, *in litt.* 1999).

In Idaho, productivity recorded from 1989 through 1998 ranged from 0 to 2.5 yg/pr, with an average of 1.6 yg/pr for this 10-year period (N=120). Recent productivity from 1994 through 1998 averaged 1.4 yg/pr (N=75) (Levine *et al.* 1998). In Montana, productivity between 1984 and 1998 ranged from 0.3 to 3.0 yg/pr, with an average of 1.7 yg/pr for the 15-year period (N=137). Recent productivity from 1994 through 1998 averaged 1.5 yg/pr (N=91) (D. Flath, *in litt.* 1999). In Nebraska, productivity between 1992 and 1998 for a single pair ranged from 0 to 5.0 yg/pr, with an average of 1.7 yg/pr for the 7-year period (N=7) (Lloyd Kiff, The Peregrine Fund, *in litt.* 1997; Tordoff *et al.* 1998).

For the period 1986 through 1998, New Mexico experienced a 12-year average productivity of 1.6 yg/pr (N=278). Recent productivity from 1995 through 1998 averaged 1.4 yg/pr (N=131) (S. Williams, *in litt.* 1997, 1999). In Texas, long term productivity recorded from 1975 through 1998 ranged from 0 to 2.3 yg/pr, with an average of 0.9 yg/pr (N=185) for the 23-year period. Recent productivity from 1994 through 1998 averaged 0.5 yg/pr (N=69) (McKinney 1994; B. McKinney, pers. comm. 1999).

In Utah, between 1985 and 1987, productivity averaged 0.8 yg/pr (N=117). From 1991 through 1996, productivity ranged from 0.9 to 2.0 yg/pr, with an average of 1.3 yg/pr (N=629) for the 6-year period (Bunnell 1994; F. Howe, *in litt.* 1997). In Wyoming, productivity between 1984 and 1998 ranged from 0.9 to 3.0 yg/pr, with an average of 1.7 yg/pr (N=282) for the 15-year period. Recent productivity between 1994 and 1998 averaged 1.8 yg/pr (N=179) (Joe White, Wyoming Game and Fish Department, *in litt.* 1995; R. Oakleaf, *in litt.* 1999).

In Kansas, productivity between 1993 and 1998 ranged from 0 to 3.0 yg/pr, with an average of 1.0 yg/pr (N=6) for the 4-year period (L. Kiff, *in litt.* 1997; Tordoff *et al.* 1998). In 1998, the first pair of peregrine falcons were located in South Dakota; they produced no young.

Although Texas and Arizona have exceeded their goals for number of pairs, current productivity is below the goal of 1.25 yg/pr and below their long term productivity averages by 44 and 18 percent respectively. Heavy metal contamination, particularly mercury, in adults and nestlings may be depressing productivity in Texas (Andrew Sansom, Texas Parks and Wildlife Department, *in litt.* 1995). Residual mercury contamination from mines operated along the Rio Grande River in the early 1900s is the suspected cause (B. McKinney, pers. comm. 1997). The current productivity level in Arizona is not fully understood, but may be a continuation of the variability exhibited in productivity between 1989 and 1995 (Garrison and Spencer 1996; Bruce Taubert, Arizona Game and Fish Department, pers. comm. 1999).

Kansas and South Dakota are two more States that currently have not met the productivity goal of 1.25 yg/pr. Kansas has had only one peregrine falcon pair since 1992, and breeding is sporadic each year.

Average productivity for the 11 States supporting breeding populations is 1.3 yg/pr, exceeding the goal of 1.25 yg/pr goal. Even though Texas, Kansas, South Dakota and Arizona currently have not met the productivity goal, productivity throughout the Rocky Mountain/Southwest region is more than sufficient for recruitment to exceed mortality, so dramatic population growth has resulted.

In Arizona, eggshells collected between 1978 and 1983 averaged 14.2 percent thinner, and 20 eggshell replicates collected from 1989 through 1994 averaged 13 percent thinner, than pre-DDT era eggshells (Ellis *et al.* 1989, Ward and Siemens 1995). In Colorado and New Mexico, shells from 260 eggs laid between 1977 and 1985 averaged 12 percent thinner than pre-DDT eggshells (Enderson *et al.* 1988). In another analysis of eggs from New Mexico, eggshells collected in 1977 averaged 20 percent thinner than pre-DDT eggshells, but in 1985 averaged only 14 percent thinner (Ponton *et al.* 1988). Eggshells collected in Colorado from 1973 through 1997 were as much as 25.1 percent thinner and at least 6.0 percent thinner than pre-DDT eggshells, with an average thinning of 13.5 percent. Only Colorado has achieved the objective for eggshell thickness. Sampling in Colorado in 1990, 1991, 1992, 1993, and 1994 produced measurements of 10.6, 11.7, 8.6, 8.1, and 6.0 percent thinning respectively, with an average annual mean of 9.0 percent thinning for this period (G. Craig, *in litt.* 1995). Although the recovery objective was not met in other States in the region, there is a general trend toward thicker eggshells in measurements taken since the mid-1970s (L. Kiff, pers. comm. 1995).

The Rocky Mountain/Southwest Recovery Plan did not identify a recovery objective for pesticide residue levels. However, organochlorine pesticide residues in American peregrine falcon eggs measured in Colorado and New Mexico between 1973 and 1979 averaged 26 ppm DDE, but the average declined to 15 ppm by 1980–1983 (Enderson *et al.* 1988). The average DDE concentration in 5 eggs collected in Colorado from 1986 through 1989 was 11 ppm (Jarman *et al.* 1993).

In summary, the first recovery objective in the Rocky Mountain/Southwest Recovery Plan was met; the current population of 535 pairs exceeds the goal of 183 pairs by 352 pairs. These pairs are distributed throughout the Rocky Mountain/Southwest States, meeting or exceeding the population goals in 10 of the 13 States in this

region. The second objective of sustaining a long-term average production of 1.25 yg/pr without manipulation by 1995 was met by all Rocky Mountain/Southwest States that have breeding American peregrine falcons except Texas, Kansas, South Dakota, and Arizona. By the mid-1980s the practice of fostering young into active nests was terminated, therefore, the long-term average productivity this recovery region has experienced was accomplished without nest manipulation. The current reproductive level in the 11 States with breeding populations is 1.3 yg/pr, exceeding the second objective of 1.25 yg/pr. Therefore, we consider the intent of this objective met. Based on the degree of recovery achieved, the third objective, that average eggshell thinning be no more than 10 percent from the pre-DDT era average for 5 years, appears to be conservative. The increase in numbers of American peregrine falcons indicates the subspecies has recovered without the necessity of reaching this specific recovery objective.

Eastern United States

The eastern peregrine population has a unique history and complex status under the Act. As stated previously, peregrine falcons were extirpated in the eastern United States and southeastern Canada by the mid-1960s. In 1974, shortly after the passage of the Act, the National Audubon Society sponsored a meeting of experts in peregrine biology, including representatives from the Service, to address the conservation of the species in North America (U.S. Fish and Wildlife Service 1991). This sparked the beginning of an effort to reestablish the peregrine in the eastern United States through the introduction of offspring from parents of multiple subspecies. Peregrine falcons were raised in captivity from parent subspecies then listed as endangered (*Falco peregrinus anatum, F. p. tundrius, F. p. peregrinus*), unlisted subspecies (*F. p. pealei, F. p. brookei, etc.*), and combinations of these subspecies. The first experimental releases of captive-produced young in the eastern States occurred in 1974 and 1975 (Cade 1994). These and future releases, coordinated by the Service, State fish and wildlife agencies, and representatives of The Peregrine Fund, demonstrated that hacking, the practice of retaining and feeding young captive-bred birds in partial captivity until they learn to fly and hunt on their own, was an effective method of introducing captive-bred peregrines to the wild (U.S. Fish and Wildlife Service 1991).

In 1978, we issued a policy statement confirming support for the use of North American peregrines to establish an eastern peregrine falcon population, supported with endangered species funds, and the use of peregrines from other geographic areas for specific research purposes. The policy applied only to peregrine falcons in the east (Keith M. Schreiner, U.S. Fish and Wildlife Service, *in litt.* 1978).

Thus, notwithstanding the similarity of appearance designation, we have continued to fully support the restoration of the eastern peregrine falcon under the 1991 revised Peregrine Falcon Eastern Population Recovery Plan. We have given the eastern peregrine falcon equal consideration with the American peregrine falcon with respect to recovery.

The Peregrine Falcon Eastern Population Recovery Plan (Eastern Plan), first published in 1979, and revised in 1985 and 1991 (U.S. Fish and Wildlife Service 1991), addressed the recovery of the peregrine falcon in the Eastern United States, a population re-established beginning in 1974 and 1975 by releasing captive-bred peregrine falcons of mixed genetic heritage. The recovery plan established two recovery objectives (1) establish a minimum of 20–25 nesting pairs in each of 5 recovery units and sustained them for a minimum of 3 years; and (2) an overall minimum of 175'200 pairs demonstrating successful, sustained nesting. The five recovery units are (1) Mid-Atlantic Coast, (2) Northern New York and New England, (3) Southern Appalachians, (4) Great Lakes, and (5) Southern New England/Central Appalachians.

The first recovery objective is nearly achieved, with three of the five recovery units (Mid-Atlantic Coast, Northern New York and New England, and Great Lakes) surpassing 20 to 25 nesting pairs of peregrine falcons for 3 years. The Mid-Atlantic Coast unit had 65 pairs fledging 110 young in 1998 and averaged 62 pairs and 90 fledglings annually from 1996 through 1998. The Northern New York and New England unit had 50 pairs fledging 70 young in 1998 and averaged 47 pairs and 61 fledglings annually from 1996 through 1998. The Great Lakes unit had 44 pairs fledging 95 young in 1998 and averaged 40 pairs and 74 fledglings from 1996 through 1998. The Southern Appalachians unit had 14 pairs fledging seven young in 1998, and averaged 11 pairs fledging 14 young from 1996 through 1998. The Southern New England and Central Appalachians unit had 20 pairs fledging 26 young in 1998 and averaged 15 pairs fledging 22 young from 1996 through 1998 (L. Kiff, *in litt.* 1997; David Flemming, U.S. Fish and Wildlife Service, *in litt.* 1997; Mike Amaral, U.S. Fish and Wildlife Service, *in litt.* 1999). In 1998, there was a total of 193 pairs counted in the five eastern State recovery units, which was the upper minimum recovery level of the Eastern Plan. The recovery goal, however, was probably met in 1997, because up to 10 percent of territorial pairs in any given year are believed to escape detection and are not counted (Cade *et al.* 1988). Importantly, the number of territorial pairs recorded in the eastern peregrine falcon recovery area has increased an average of 10 per cent annually for the past 7 years (1992–1998). Equally important is that the productivity of these pairs during the same 7-year period has averaged 1.5 yg/pr, thus demonstrating sustained successful nesting.

As of 1998, there were at least 32 nesting peregrine pairs in six midwestern States, which is outside the recovery area delineated in the 1991 Eastern Plan. The birds are nesting successfully in a larger area than was believed likely in 1991. Peregrine falcons now found in midwestern States are the result of captive-reared and released birds, and others that probably came from the peregrine falcons released in the eastern States. However, there appears to be a zone of no nesting in the northeastern Great Plains that separates the western American peregrine falcons from the introduced eastern peregrine falcons (Chuck Kjos, U.S. Fish and Wildlife Service, pers. comm. 1997). There are now more than 225 pairs of peregrine falcons in the midwestern and eastern States where peregrine falcons were extirpated.

Mexico

None of the existing recovery plans written for peregrine falcons in North America established recovery criteria for birds that nest in Mexico. There is very little historical or recent information on peregrine falcons in Mexico to accurately assess their current status in Mexico.

Porter *et al.* (1988) reported 42 known nesting territories on the western side of the Baja California Peninsula. From 1966 through 1971, only three pairs occurred in this region and none were found in 1976 (Porter *et al.* 1988), indicating a substantial decline had occurred by the mid-1970s. Most of these territories apparently were checked since that time, but seven pairs were located between 1985 and 1992 in areas not occupied in previous years (Massey and Palacios 1994).

In 1993, three active American peregrine falcon nests were discovered in Ojo de Liebre (Scammon's Lagoon) on the western side of the Baja California Peninsula in an area without historical nesting records (Castellanos *et al.* 1994). The central west coast of the Baja California Peninsula was an important breeding area with a historical population of about 13 pairs (Banks 1969). Between 1980 and 1994, Castellanos *et al.* (1997) conducted breeding surveys of American peregrine falcons in this area of the coast and found 10 nesting pairs. Castellanos *et al.* (1997) studied the reproductive success of three pairs in 1993 and five pairs in 1994 located at Ojo de Liebre and San Ignacio Lagoons. An average of three eggs, 1.8 nestlings, and 1.6 fledglings were produced per nest. This productivity appears to be within the range of normal productivity for healthy populations (Cade *et al.* 1988). These observations suggest some recent recovery on the west coast of the Baja California Peninsula.

On the western (Gulf of California) side of mainland Mexico, Porter *et al.* (1988) reported 23 historical nest sites. A number of new nest sites were found in this area between 1966 and 1984, increasing the number of known nest sites to 51. Territory occupancy averaged about 82 percent between 1967 and 1971 and 77 percent between 1971 through 1975, indicating that territory occupancy in that area never declined as significantly as on the west side of the Baja California Peninsula. Porter and Jenkins (1988) believed that the number of occupied territories in the Gulf area increased after 1967 following a reduction in DDE residues in prey.

Between 1989 and 1997, Robert Mesta, (*in litt.* 1997) found three pairs of American peregrine falcons, one pair on the Rio Aros and two on the Rio Yaqui, Sonora. Hunt *et al.* (1988) found 14 occupied nesting territories in the highlands of northeast Mexico in 1982. In this area and adjacent west Texas, territory occupancy averaged about 70 percent during 1973–1985.

Most of what is known about productivity and pesticide residues in Mexico comes from the western mainland near the Gulf of California. Porter *et al.* (1988) found that productivity along the Gulf of California between 1965 and 1984 was ''somewhat less than normal,'' and five addled eggs collected between 1976 and 1984 averaged 12.8 ppm DDE with a range of 2.4 to 25.0 ppm (Porter and Jenkins 1988). DDE residues in prey in the Gulf area declined from the 1960s to the 1980s, and this decline correlated with increases in productivity and the number of breeding pairs (Porter and Jenkins 1988). Some prey, however, still contained high pesticide residues, and reproduction appeared to be affected by organochlorine at three of 15 nests examined (Porter and Jenkins 1988).

Hunt *et al.* (1988) found that only five of 14 pairs produced young in northeast Mexico in 1982. Hunt *et al.* (1988) reported significant DDE residues in peregrine falcon prey species in western Texas in the mid 1980s, but prey species in Mexico were not sampled.

In summary, there was little research on the distribution, numbers, and status of American peregrine falcons in Mexico, and most research took place in the Baja California Peninsula and the Gulf of California regions. Numbers on the west coast of the Baja California Peninsula declined significantly (Porter *et al.* 1988), but observations suggest that numbers may have increased in recent years (Massey and Palacios 1994; Castellanos *et al.* 1994; and Castellanos *et al.* 1997). In the Gulf of California area, territory occupancy never was known to drop below 77 percent (Porter *et al.* 1988), and it increased in the 1970s and 1980s (Porter and Jenkins 1988).

No information on population trends for American peregrine falcons in Mexico is available. However, the status of the Mexican population may be similar to that of the population occupying similar habitat in nearby Arizona (G. Hunt, pers. comm. 1997). Exposure to organochlorine-based pesticides by Mexico nesting populations continues to be a concern. In 1997, as part of the North American Agreement for Environmental Cooperation, a parallel agreement to the North American Free Trade Agreement between the United States, Canada, and Mexico, the Commission for Environmental Cooperation (CEC) established a North American Regional Action Plan (NARA) on DDT. Mexico, a member nation of the CEC, proposes a phased reduction of DDT (Philip Johnson, U.S. Fish and Wildlife Service, pers. comm. 1999). Specific goals of this reduction are: (1) Reduce the use of DDT for malaria control in Mexico by 80 percent in 5 years (beginning in 1997); (2) eliminate the illegal use of DDT in agriculture in Mexico; (3) develop a cooperative approach to minimize movement of malaria-infected mosquitos across borders and reduce the illegal importation of DDT; and (4) advance global controls on DDT production, export and use.

Adverse effects of organochlorine pesticides in the environment remains an international concern for peregrine falcons nesting in Mexico, and for peregrine falcons wintering in or migrating through Latin America. By undertaking the steps proposed in the NARA, the United States, Canada, and Mexico are committing to ongoing cooperative activities and yearly reporting on progress made on these initiatives and objectives. Annual reports will be submitted to the North American Working Group for the Sound Management of Chemicals and subsequently disseminated to the Council of the Commission for Environmental Cooperation and the public.

Summary of Peregrine Falcon Recovery

Five regional peregrine falcon recovery plans, four for American peregrine falcons in Canada and the western United States, and one for the eastern United States introduced peregrine falcon population, were written to guide recovery efforts and establish criteria to be used in measuring recovery. These recovery plans included objectives for population size and reproductive performance. Only two of the recovery plans included specific objectives that applied to pesticide residues in eggs and eggshell thinning. The combined breeding population size goal for the four American peregrine falcon recovery plans is 456 pairs. Currently, a minimum of 1,425 pairs occupy the range of the American peregrine falcon in Alaska, Canada, and the western United States. There are 193 peregrine falcon pairs in the five recovery units included in the Eastern Plan, and an additional 32 peregrine falcon pairs occur in midwestern States in areas not included in the Eastern Plan recovery units. In 1998, the total known breeding population of peregrine falcons was 1,650 pairs in the United States and Canada.

Productivity is an important measure of population health, and each of the four American peregrine falcon recovery regions met or exceeded their respective productivity goals, as did the eastern peregrine population.

Other objectives, including those for pesticide residues in eggs and the degree to which eggshells are thinner than pre-pesticide era eggshells, vary among the plans. In the case of eggshell thinning, current measurements obtained in some areas fall short of recovery objectives. Eggshell thinning was originally suggested by recovery teams as an indicator of whether organochlorine contamination was preventing species recovery. Despite the failure of populations in localized areas to meet recovery objectives, overall, populations of American peregrine

falcons have increased considerably. This increase continues to occur even after reintroduction efforts were curtailed. The consistent and geographically widespread trends in increasing population size demonstrate that current levels of reproductive failure, pesticide residues, and eggshell thinning still affecting American peregrine falcons in some areas have not prevented recovery of the subspecies in North America.

Table 1 summarizes the recovery plan goals for each of the regions and Canada, as well as the current recovery status.

TABLE 1.—AMERICAN PEREGRINE FALCON RECOVERY PLAN GOALS AND CURRENT (1998) RECOVERY STATUS.

Recovery plan	Delisting goal	Current status	Comments/degree to which delisting goals are met
Alaska:			
Pairs	28 pairs in study areas.	79 pairs in study areas.	Exceeded goal by 51 pairs in study areas. Approximately 301 pairs known State-wide.
Productivity (young/pair)	1.8 yg/pr	1.9 yg/pr	Exceeded goal.
DDT (parts per million)	less than 5 ppm	3.5 ppm	Exceeded goal.
Eggshell thinning	less than 10 percent.	12.1 percent	Goal not met, but has not prevented recovery; goal probably too conservative.
Canada:			
Pairs	60 pairs (10 each in 6 zones).	319 pairs	Exceeded goal by 259 pairs.
Productivity	1.5 yg/pr	1.8 yg/pr	Exceeded goal.
Pacific Coast:			
Pairs	185 pairs	270 pairs	Exceeded goal by 85 pairs.
Productivity	1.5 yg/pr	1.5 yg/pr	Goal met.
Rocky Mountain/Southwest:			
Pairs	183 pairs	535 pairs	Exceeded goal by 352 pairs.
Productivity	1.25 yg/pr	1.3 yg/pr	Exceeded goal.
Eggshell thinning	less than 10 percent.		Goal measured by only a few States; cannot be assessed.
Eastern/Great Lakes:			
Pairs	175–200 pairs (with no fewer than 20–25 in each of 5 recovery zones).	193 pairs	Exceeded goal in 3 zones; goals in other 2 zones probably were met; an additional 32 peregrine falcon pairs occur in several Midwestern States not included under the Eastern Plan.

Summary of Issues and Recommendations

In the August 26, 1998, proposed rule (63 FR 45446), we requested that all interested parties provide information and comments on the status of and proposal to delist the American peregrine falcon. Announcements of the proposed rule were sent to Federal, State, county, and city-elected officials, Federal and State agencies, interested private citizens, and local area newspapers and radio stations. We provided the governments of Canada and Mexico with the proposed rule, and both countries responded with comments. We held public hearings on December 3, 1998, in Wisconsin and December 8, 1998, in New Hampshire. In addition, we solicited formal scientific peer review of the proposal in accordance with our July 1, 1994, Interagency Cooperative Policy for Peer Review in Endangered Species Act Activities (59 FR 34270). We requested three individuals, who possess expertise in peregrine falcon biology, to review the proposed rule by the close of the comment period. All three individuals responded to our request and their comments were incorporated into this final rule.

We considered all comments, including oral testimony at the public hearings. We received a total of 29 oral comments and 893 comment letters from 49 States, and the District of Columbia, Canada, Mexico, Germany, Bali, four Federal agencies, 27 State resource agencies, 305 falconry associations or individual falconers, and 40 conservation organizations. Of the comments received, 633 supported the proposal to delist, 266 opposed the proposal, 11 supported downlisting, and 12 letters duplicated comments from individuals who previously provided oral comments.

Because many respondents offered similar comments, those comments of a similar nature are grouped. These comments, and our responses, are presented below.

Issue 1: In the Midwest, delisting will result in less cooperation by building owners and managers to protect peregrine falcons nesting on their buildings.

Our Response: Currently, 28 States in the midwestern and eastern United States support nesting peregrine falcons. Approximately 87 percent of the midwestern pairs and 33 percent of the eastern pairs are nesting on manmade structures: bridges, buildings and smokestacks (Martell and McNicoll 1999). Currently, there are 117 nests on nest boxes or trays in 19 States and the District of Columbia. Should delisting the peregrine falcon act as a disincentive for owners and managers to protect nesting peregrine falcons on their buildings, the long-term security of this urban population could be threatened (Martell and McNicoll 1999).

Between January and March of 1999, 75 people with information on 95 of the 117 nest sites were asked if delisting would affect their current management strategies. Responses were overwhelmingly in favor of continuing to manage for the presence of nesting pairs for some of the following reasons: pigeon control, good public relations, positive effect on building employees, and good environmental stewardship (Martell and McNicoll 1999). Survey results do not suggest that delisting of the peregrine falcon would result in widespread removal of nest boxes and trays or discouragement of nesting on manmade structures. Furthermore, the survey found the public widely appreciated and accommodated

peregrines at the manmade structures on which they nest (Martell and McNicoll 1999).

Issue 2: Disturbance due to recreational rock climbing poses a threat to nesting peregrine falcons.

Our Response: The increasing popularity of rock climbing throughout North America, particularly in the northeast, is becoming a serious problem for land managers trying to protect nesting peregrine falcons. Unlike the western landscape that provides rock climbers with more and larger cliffs and thus some alternatives to conflicts with nesting peregrine falcons, the smaller and limited cliffs of the northeast present fewer alternatives to peregrine/climber conflicts.

The peregrine falcon will still be protected by the MBTA. Additional protection is provided by other laws such as the National Forest Management Act (16 U.S.C. 1600) and the Federal Land Management and Policy Act (43 U.S.C. 1701). These continued protections are adequate to address this threat. See Factor D under Summary of Factors Affecting the Species.

In addition, we are aware of several very effective raptor management plans that were cooperatively developed by land managers, representatives of the climbing community, and other interested parties (plans that contain effective public education components). Some examples include plans developed by the Prescott National Forest in Arizona, Yosemite National Park in California, Adirondack State Park in New York, Zion National Park in Utah, Smith Rock State Park in Oregon, the Nantahala National Forest in North Carolina, and the Colorado National Monument in Colorado. All of these plans include seasonal rock climbing restrictions to prevent disturbance of raptor nests from rock climbing activities. The development of more of these partnerships is essential to the preservation of the peregrine falcon and the sport of rock climbing. Organizations like the Access Fund which represent the climbing community have continued to express a strong desire to work with both private and public land managers to resolve any conflicts originating from the use of cliffs by climbers.

Issue 3: The Act's section 6 funds currently being used by States to support peregrine falcon monitoring programs will not be available once the peregrine is delisted.

Our Response: We are authorized through the Secretary of the Interior to provide grants to States to assist in monitoring the status of recovered species pursuant to section 4(g) under section 6 of the Act. Existing and future Federal assistance in the form of section 6 funding to States for conservation work will not be affected by the delisting, as long as States continue to identify monitoring peregrine falcons as a high priority.

Issue 4: The data do not support delisting the American peregrine falcon throughout its range in the United States. The Service should consider downlisting the American peregrine falcon to threatened rather than delisting.

Our Response: Recent data show improvements in numbers of breeding pairs of peregrine falcons and productivity (Refer to Table 1, ''Recovery Status,'' and ''Summary of Peregrine Falcon Recovery''), and demonstrate that goals set for numbers and productivity for the American peregrine falcon recovery plans were met or exceeded. The combined population size goal for the four American peregrine falcon recovery plans is 456 pairs. Currently, a minimum of 1,425 known pairs occupy sites in Alaska, Canada, and the western United States, and a number of additional pairs have probably gone undetected. Overall average productivity goals in all four American peregrine falcon recovery plans, using productivity as a recovery criterion, were met or exceeded.

Only the Alaska recovery plan set a goal for DDT levels, and only two recovery plans (Alaska and Rocky Mountain/Southwest) specified objectives for eggshell thinning. The Alaska Recovery Plan set a delisting goal of less than 5 ppm DDT and less than 10 percent eggshell thinning. Recent data for American peregrine falcon eggs in Alaska indicate DDT levels at less than 3.5 ppm, exceeding that goal, and eggshell thinning is at 12.1 percent. Measurements for eggshell thinning were not consistently taken in the Rocky Mountain/Southwest States. Colorado has met the recovery plan eggshell thinning goal of less than 10 percent; the average of the annual means for 1990–1994 was 9.0 percent. Data for other States show a general trend toward thicker eggshells since the mid-1970s (refer to Rocky Mountain/Southwest section under Recovery Status).

Three of 5 peregrine falcon recovery units in the eastern United States have met recovery goals, and 193 pairs documented in 1998 indicate the overall recovery goal of 175–200 pairs was met. In addition, another 32 pairs are nesting in areas of the Midwest outside the recovery units specified in the Eastern Plan but nevertheless contribute to overall restoration goals.

We believe that the species has essentially achieved the goals established for recovery and, in many areas, has exceeded the goals. We believe the available information supports full delisting of the species throughout its range, and the species clearly is not in danger of extinction, is not likely to become endangered within the foreseeable future throughout a significant portion of its range, and warrants full delisting.

Issue 5: American peregrine falcons should not be delisted because they are not restored throughout the historical range.

Our Response: We have determined the American peregrine falcon has recovered throughout its historical range. Restoration of the American peregrine falcon within every area throughout its historical range is not required by the Act, is not required for recovery, nor was it a goal of any of the recovery plans. Generally, the goal of a recovery program is to restore the species to a point at which protection under the Act is no longer required. To be recovered, a species must not be endangered with extinction, or be likely to become endangered within the foreseeable future. Although a few, localized areas have not quite met their numerical recovery goals, the overall status of the American peregrine falcon has improved significantly such that it is considered recovered and warrants delisting. As a species recovers in numbers and populations expand, more of the historical range can be re-occupied where appropriate habitat remains.

Issue 6: There are gaps in the scientific knowledge about American peregrine falcon biology. A population viability analysis was not done, and genetic diversity, viable population size, population dynamics, and long-term stability of populations have not been determined.

Our Response: A complete understanding of the biology of a species is not required to determine a species' conservation status under the Act. Population viability analyses are important tools for attempting to quantify threats to a species, particularly those facing loss and fragmentation of habitat, and the consequences of conservation actions, as well as aiding in identifying critical factors for study, management, and monitoring. These analyses are not always essential, however, to determine when a species has achieved recovery, particularly in the case of the American peregrine falcon. It is evident that

recovery of this subspecies was largely achieved by eliminating the use of DDT and by successful management activities, including the reintroduction of captive-bred American peregrine falcons. Recovery goals established for the species were met or exceeded, with few exceptions.

Issue 7: Organochlorine pesticides still persist within the breeding range of the American peregrine falcon and continue to depress natural productivity.

Our Response: We recognize that although the peregrine falcon has made a dramatic recovery throughout its historical range in the United States, the presence of environmental contaminants is still affecting the productivity of certain regional populations. Eggs collected on the eastern shore of Virginia and Maryland had slightly elevated levels of DDE, dieldrin, and mercury, which was associated with reproductive problems (U.S. Fish and Wildlife Service 1994). On the Channel Islands in California, particularly Catalina, populations are still affected by organochlorine residues and eggshell thinning (Jarman 1994). In west Texas, heavy metal contamination, particularly mercury may be depressing productivity (A. Sansom, *in litt.*1995). Residual mercury from mines operated along the Rio Grande River in the early 1900s is the suspected source of this contamination (B. McKinney, pers. comm. 1997). We recognize the possible threat that environmental contaminants pose to the sustained recovery of this species and therefore, will include a contaminant monitoring component in the post-delisting monitoring plan. Refer to Factor E under Summary of Factors Affecting the Species, for an in-depth discussion of contaminants. See also our response to issue 8.

Issue 8: The continued unrestricted use of organochlorine pesticides in Latin America places the American peregrine falcon at risk of contamination while on migration and on its wintering grounds.

Our Response: Comparisons of blood samples collected during fall and spring migration indicate that, although migrant peregrine falcons are known to accumulate pesticides while wintering in Latin America, DDE residues in the blood taken from female peregrine falcons captured during spring migration at Padre Island, Texas decreased between 1978 and 1994 below levels that would affect reproduction (Henny *et al.* 1996). Despite the use of organochlorines in Latin America, the American peregrine falcon has recovered over its historical range, and Arctic peregrine falcons, which also winter in Latin America, were delisted due to their recovery. Refer to Factor E under Summary of Factors Affecting the Species for an in-depth discussion. The North American Working Group for the Sound Management of Chemicals promotes a regional perspective that encourages the active involvement of Central and South American countries in the implementation of the North American Regional Action Plan on DDT, and is facilitating international cooperation on combating malaria in these regions without the continued use of organochlorine pesticides. This effort could eventually eliminate or reduce one source of DDT in Central and South American countries.

Issue 9: The take of American peregrine falcons for falconry after its delisting will create an additional threat to the subspecies.

Our Response: Delisting the American peregrine falcon will not affect the protection given to all migratory bird species, including the peregrine falcon, under the MBTA. The regulations issued pursuant to the MBTA allow for issuance of permits to take raptors for falconry and other purposes provided the taking will not threaten wildlife populations (50 CFR 21.28 and 13.21(b)). Currently we are working with State wildlife agencies to develop biological criteria and two management plans to govern the issuance of permits for take of peregrine falcons to ensure the taking does not negatively impact wild populations, particularly those in need of further restoration. The first management plan will deal with the take of eyas (nestling) peregrines. A second management plan will deal with the take of passage (migrating first-year) peregrines. The management plans will include criteria for harvest, implementation criteria, and procedures for evaluating effects of the harvest. They will pertain to the take of all wild peregrine falcons in the U.S., including the American peregrine falcon, and will apply to all falconry, raptor propagation, and scientific collecting permits. Take will not be permitted under the MBTA until the draft management plans undergo public review, are approved, finalized, and published in the **Federal Register**. Some exceptions may be made on a case-by-case basis for scientific purposes. The effects of take for all purposes will be assessed during the monitoring period following delisting. Refer to Factor D under the Summary of Factors Affecting the Species section and the Effects of This Rule section for further information.

Issue 10: The Canadian Wildlife Service has expressed concern that American peregrine falcons breeding in Canada but migrating to or through the United States will be taken for falconry purposes.

Our Response: Canada's recovery program for American peregrine falcons is still in progress and the Canadian government is concerned that any take of American peregrines migrating from Canada could impact recovery. We are working with the governments of Canada and Greenland in considering the appropriateness of harvest of peregrines migrating through the United States. If take of these passage birds is approved, it would be designed to avoid take of American peregrines originating in Canada and instead target the more abundant Arctic peregrines from northern Alaska, Canada, and Greenland.

Issue 11: The Service cannot consider delisting the American peregrine falcon until all recovery goals in the four existing recovery plans for this subspecies are met or exceeded.

Our Response: Section 4(f) of the Act directs us to develop and implement recovery plans for species of animals or plants listed as endangered or threatened. Recovery is the process by which the decline of an endangered or threatened species is arrested or reversed and threats to its survival are neutralized so that long-term survival in nature can be ensured. The goal of this process is the maintenance of secure, self-sustaining wild populations of species with the minimum investment of resources. One of the main purposes of the recovery plan is to enumerate goals (guidelines) that will help us to determine when recovery for a particular species is achieved. Meeting or exceeding all of the specific recovery goals for a listed species is not required by the Act before delisting can occur.

We determine whether recovery is achieved based on a species' performance relative to the goals set in its recovery plan and the best available scientific information. A species is considered recovered when it is no longer in danger of extinction (i.e., endangered), or likely to become endangered within the foreseeable future throughout all or a significant portion of its range (i.e., threatened). The American peregrine falcon has either met, exceeded, or is very close to meeting the recovery goals set for this subspecies throughout its range. We believe that the intent of all the objectives are met and that the recovery of the subspecies justifies delisting.

Issue 12: The eastern peregrine falcon population has not met the recovery goals set forth in the Eastern Recovery

Plan and, therefore, should remain on the endangered species list.

Our Response: The eastern peregrine falcon population is protected only due to the similarity of appearance to *F. p. anatum*, which has protected individual eastern peregrine falcons from direct take. Thus, their status with respect to recovery has no direct impact on the decision to delist the American peregrine falcon. Nevertheless, we have supported and still fully support the restoration of this population.

Data through 1998 on the status of the eastern peregrine falcon population indicate that the intent of the recovery goals set for this population are met. The recovery plan established 2 recovery objectives including (1) a minimum of 20–25 nesting pairs in each of 5 recovery units which are established and sustained for a minimum of 3 years, and (2) an overall minimum of 175–200 pairs demonstrating successful, sustained nesting. Three of the five recovery units (Mid-Atlantic Coast, Northern New York and New England, and Great Lakes) have surpassed the nesting pair goal for 3 years. The Southern Appalachians and Southern New England/Central Appalachians units may not yet have achieved the goals established for the number of breeding pairs for those areas. However, the overall minimum of 175–200 successful pairs in the eastern region was achieved, and over the past 6 years (1992–1998), the number of territorial pairs has increased an average of 10 percent annually. There are now at least 193 pairs of peregrine falcons in the eastern States where falcons were extirpated, and pairs are successfully nesting throughout a greater range than was anticipated. We believe the intent of the recovery objectives are satisfied and that recovery of the peregrine in the eastern United States is sufficiently established. Refer to the Recovery Status section for additional discussion on this subject.

Issue 13: The status of the American peregrine falcon in Mexico was not adequately addressed.

Our Response: While population status and trends for falcons nesting in Mexico are not well known, American peregrine falcon populations in the United States and Canada, including those migrating to and from Latin America, have met or exceeded their criteria for delisting. Restoration of the American peregrine falcon within every area throughout its historical range is not required by the Act, nor is it required for recovery. Mexico's proposed phased reduction of DDT under the North American Regional Action Plan will make a significant contribution toward increasing peregrine falcon populations in Mexico. Refer to the Mexico section under Recovery Status for additional discussion on this subject.

Issue 14: The Service's delisting proposal is not supported by an adequate scientific review.

Our Response: The proposed rule to remove the peregrine falcon in North America from the Federal List of Endangered and Threatened Wildlife received reviews from a variety of scientific institutions and individual scientists. Two examples are the Ornithological Council and the Raptor Research Foundation. The Ornithological Council consists of nine leading scientific ornithological societies: the American Ornithologists' Union, Association of Field Ornithologists, Consejo Internacional para la Preservaciòn de las Aves, Cooper Ornithological Society, Colonial Waterbird Society, Pacific Seabird Group, Raptor Research Foundation, Society of Caribbean Ornithology, and Wilson Ornithological Society. Together it has a membership of approximately 6,500 ornithologists. One of its primary missions is to provide scientific information about birds to legislators, regulatory agencies, industry decision makers, conservation organizations and others, and to promote the use of scientific information in the making of policies that affect birds.

The task of evaluating the proposed rule on behalf of the Ornithological Council was accepted by a committee of Raptor Research Foundation scientists. The Raptor Research Foundation is a scientific society that represents professional raptor scientists and managers throughout North America and around the world. This committee of raptor scientists reviewed the available data and submitted a report that was endorsed by both the Ornithological Council and the Raptor Research Foundation as their position on the proposed rule. This report underwent peer review and was published in the Wildlife Society Bulletin (Millsap *et al.*, 1998, WSB 26(3); 522–538). While expressing some concern about the status of the eastern peregrine population, the authors concurred with our position that the peregrine falcon warranted delisting range-wide.

Issue 15: Recovery plans used to evaluate the recovery of the peregrine falcon are out of date and need to be revised to reflect more accurate contemporary goals and the Service should not misrepresent the goals in the current plans.

Our Response: As addressed in our response to Issue 11, section 4(f) of the Act directs us to develop and implement recovery plans for species of animals or plants listed as endangered or threatened. Recovery is the process by which the decline of an endangered or threatened species is arrested or reversed and threats to its survival are neutralized so that long-term survival in nature can be ensured. One of the main purposes of the recovery plan is to enumerate goals (guidelines) that will help us to determine when recovery of a particular species is achieved. Meeting or exceeding all of the specific recovery goals for a listed species before it can be delisted is not required by the Act. Section 4 of the Act and regulations (50 CFR Part 424) promulgated to implement the listing provisions of the Act, establish the procedures for listing, reclassifying, and delisting species. We may list a species if one or more of the five factors described in section 4(a)(1) of the Act threatens the continued existence of the species. A species may be delisted, according to 50 CFR 424.11(d), if the best scientific and commercial data available substantiate that the species is neither endangered or threatened because of (1) extinction, (2) recovery, or (3) the original data for classification of the species were in error. We have determined that substantial peregrine falcon recovery has taken place, and none of the five factors addressed in section 4(a)(1) of the Act is currently negatively affecting the peregrine falcon to the degree that the species is endangered or threatened.

Issue 16: Post-delisting monitoring for at least 5 years is essential.

Our Response: We agree. Section 4(g)(1) of the Act requires the Secretary to implement a system, in cooperation with the States, to monitor for not less than 5 years the status of all species which have recovered to the point that protection of the Act is no longer required (section 4(g)). If it becomes evident during the course of the post-delisting monitoring that the species again requires the protection of the Act, it would be relisted.

Summary of Factors Affecting the Species

Section 4 of the Act and regulations (50 CFR Part 424) promulgated to implement the listing provisions of the Act, set forth the procedures for listing, reclassifying, and delisting species on the Federal lists. We may list a species if one or more of the five factors described in section 4(a)(1) of the Act threatens the continued existence of the species. A species may be delisted, according to 50 CFR 424.11(d), if the

best scientific and commercial data available substantiate that the species is neither endangered or threatened because of (1) extinction, (2) recovery, or (3) the original data for classification of the species were in error.

After a thorough review of all available information, we have determined that substantial peregrine falcon recovery has taken place since the early 1980s. We determined that none of the five factors addressed in section 4(a)(1) of the Act, and discussed below, is currently affecting the species, including the American peregrine falcon subspecies and introduced peregrine falcon populations, such that the species is no longer endangered (in danger of extinction throughout all or a significant portion of its range) or threatened (likely to become endangered in the foreseeable future throughout all or a significant portion of its range). These factors and their application to the peregrine falcon in North America are as follows:

A. The Present or Threatened Destruction, Modification, or Curtailment of Its Habitat or Range

Peregrine falcons occupy a variety of habitat types and nest from the boreal forest region of Alaska and Canada, through much of Canada and the western United States, south to parts of central and western Mexico. Nesting habitat includes cliffs and bluffs in boreal forests, coastal cliffs and islands, urban skyscrapers and other structures, and cliffs and buttes in southwestern deserts. In some breeding areas, such as the southern United States, some or all of the birds remain year-round on their nesting territories. In other breeding areas, particularly in high latitudes, many or all of the individuals are highly migratory; these individuals occupy a number of regions and habitat types throughout the year as they nest, migrate to and from wintering areas, and occupy their wintering ranges. Due to the extensive geographic distribution of the peregrine falcon, the wide variety of habitat types in which the species nests, and the immense area that some of the more migratory individuals occupy during a year, the peregrine falcon occupies an extremely broad array of areas and habitats throughout its range. As a result, the degree to which peregrine falcons were affected by human-caused habitat modification varies widely by region, habitat type, and individual falcons within the population.

As the human population has grown in North America, the rate of habitat alteration has unquestionably increased. Certainly some peregrine falcon habitat was destroyed, such as the many wetlands drained in recent years that were previously used by peregrine falcons for foraging or as migratory staging areas during spring and fall. But peregrine falcons have colonized many cities in North America due to the abundance of nest sites on buildings and the abundance of prey, such as rock doves (*Columba livia*), that thrive in urban areas. Therefore, some forms of habitat modification have negatively affected peregrine falcons while other forms have benefited them. It would be burdensome to estimate the net, overall effect of habitat modification on the species throughout North America.

Although the rate of habitat modification in North America has increased in recent decades, the number of American peregrine falcons occupying the region has increased substantially since the late 1970s or early 1980s. In several parts of their range, including parts of Alaska, the Yukon and Northwest Territories, California, and the southwestern United States, the number of breeding pairs has increased rapidly in recent years, and some local populations now occur at very high densities (R. Ambrose, pers. comm. 1997; G. Holroyd, pers. comm. 1997; Enderson *et al.* 1995). Because these rapid population growth rates and high densities were achieved despite habitat modification in North America, we conclude that habitat modification or destruction was not a limiting factor in peregrine recovery. It does not currently threaten the existence of the American peregrine falcon nor is it likely to in the foreseeable future.

B. Overutilization for Commercial, Recreational, Scientific, or Educational Purposes

Delisting the peregrine falcon will not result in overutilization because the delisting will not affect protection provided the peregrine falcon by the MBTA. The take of all migratory birds, including peregrine falcons, is governed by the MBTA's regulations on the taking of migratory birds for educational, scientific, and recreational purposes and requiring harvest be limited to levels that prevent overutilization (See Factor D).

C. Disease or Predation

Peregrine falcons are susceptible to a number of diseases and parasites such as tapeworms, mites, ticks, botulism, fowl pox, and viral encephalitis (U.S. Fish and Wildlife Service 1982b; Trainer (1969) as cited in U.S. Fish and Wildlife Service 1984). However, these organisms are not known to affect the peregrine falcon at the population level.

Mammals and other raptors are known to prey on peregrine falcons, including such species as the great horned owl (*Bubo virginianus*), red-tailed hawk (*Buteo jamaicensis*), raccoon (*Procyon lotor*), and coyote (*Canis latrans*) (U.S. Fish and Wildlife Service 1982b, 1984). For example, great horned owls are natural predators of peregrine falcons (U.S. Fish and Wildlife Service 1991) and are possibly responsible for the slow recovery of peregrine falcons in the two northern recovery areas in the reestablished eastern population (M. Amaral *in litt.* 1995). Great horned owl predation was not documented as a significant cause of the decline in peregrine falcons and has not affected the species' overall recovery.

Golden eagles (*Aquila chrysaetos*) are also known to prey on young peregrine falcons. Barbara Behan (U.S. Fish and Wildlife Service, pers. comm. 1999) witnessed a golden eagle prey on young peregrine falcons at a hack site in Colorado, stooping and footing one of the falcons, and leaving the area with it in its talons. The same eagle, or another, returned numerous times over the next several days, and the other four falcons disappeared in that time, despite efforts by the hack site attendants to scare the eagles away from the site.

Though the peregrine falcon is occasionally preyed upon, this factor is not known to affect the peregrine falcon at the population level.

D. The Inadequacy of Existing Regulatory Mechanisms

Protection from take and commerce for the peregrine falcons under the Endangered Species Act will be removed upon delisting. However, peregrine falcons are still protected by the MBTA. Section 704 of the MBTA states that the Secretary of the Interior is authorized and directed to determine if, and by what means, the take of migratory birds is allowed and to adopt suitable regulations permitting and governing the take. In adopting regulations, the Secretary is to consider such factors as distribution and abundance to ensure that take is compatible with the protection of the species.

The MBTA and its implementing regulations (50 CFR Parts 20 and 21) prohibit take, possession, import, export, transport, selling, purchase, barter, or offering for sale, purchase or barter, any migratory bird, their eggs, parts, and nests, except as authorized under a valid permit (50 CFR 21.11). Regulations at 50 CFR 21.28 and 21.30 authorize the issuance of permits to take, possess, transport and engage in

commerce with raptors for falconry and for propagation. Other regulations authorize the issuance of permits for scientific collecting (50 CFR 21.23), special purposes such as rehabilitation or education (50 CFR 21.27), and depredation (50 CFR 21.41). Prior to issuance of these permits, meeting certain criteria is required, including a requirement that the issuance will not threaten a wildlife population (50 CFR 13.21(b)(4)). In cooperation with State wildlife agencies we will develop draft biological criteria for management of take of wild peregrines under the MBTA. The resulting management plans will include biological criteria for take, implementation criteria, and procedures for evaluating the effects of the taking. It will pertain to the take of peregrines in the United States for falconry and other purposes. With limited exceptions, take will not be permitted under MBTA until the draft management plans undergo public review, are approved, finalized, and published in the **Federal Register**. In addition to considering the effect on wild populations, issuance of raptor propagation permits requires that we consider whether suitable captive stock is available and whether wild stock is needed to enhance the genetic variability of captive stock (50 CFR 21.30(c)(4)).

These existing regulatory provisions will adequately protect against excessive take of peregrine falcons. If necessary, protective measures could be expanded by promulgation of a regulation under the MBTA. We have both the legal authority and the obligation to regulate take of peregrines under the MBTA (see additional discussion of the MBTA in the Effects of this Rule section below).

In the absence of habitat protection under the Act, there are no other existing Federal laws that specifically protect the habitat of this species (see ''Critical Habitat''). However, loss of habitat was not identified as a threat to the species and was not a factor identified as contributing to the species' listing.

An important regulatory mechanism affecting peregrine falcons is the requirement that pesticides be registered with the Environmental Protection Agency (EPA). Under the authority of the Federal Insecticide, Fungicide, and Rodenticide Act (7 U.S.C. 136), the EPA requires environmental testing of all new pesticides. Testing the effects of pesticides on representative wildlife species prior to pesticide registration is specifically required. This protection from effects of pesticides are not altered by delisting the peregrine falcon.

On July 1, 1975, peregrine falcons were included in Appendix I of the Convention on International Trade in Endangered Species of Wild Fauna and Flora. This treaty was established to prevent international trade that may be detrimental to the survival of plants and animals. Generally, both import and export permits are required by the importing and exporting countries before an Appendix I species may be shipped, and Appendix I species may not be imported for primarily commercial purposes. Although CITES does not itself regulate take or domestic trade, CITES permits may not be issued if the export will be detrimental to the survival of the species or if the specimens were not legally acquired. This protection is not be altered by delisting the peregrine falcon under the Act.

Peregrine falcons are still afforded some protection by land management agencies under laws such as the National Forest Management Act (16 U.S.C. 1600) and the Federal Land Management and Policy Act (43 U.S.C. 1701). National Forest Management Act regulations specify that ''fish and wildlife habitat shall be managed to maintain viable populations of existing native and desired non-native vertebrate species in the planning area.'' (36 CFR 219.19). Guidelines for each planning area must provide for a diversity of plant and animal communities based on the suitability of a specific land area. United States Forest Service regional foresters are responsible for identifying sensitive species occurring within their Region. Sensitive species are those that may require special management emphasis to ensure their viability and to preclude trends toward endangerment that would result in the need for Federal listing. The delisting of the peregrine falcon will require Federal land managers to consider the need for designating the peregrine falcon as a sensitive species to ensure that forest management activities do not contribute to a need for relisting. The Federal Land Policy and Management Act requires that public lands be managed to protect the quality of scientific, ecological, and environmental qualities, among others, and to preserve and protect certain lands in their natural condition to provide food and habitat for fish and wildlife.

Federal delisting of the peregrine falcon will not remove the peregrine falcon from State threatened and endangered species lists, or suspend any other legal protections provided by State law. States may have more restrictive laws protecting wildlife, including restrictions on use for falconry, and may retain State threatened or endangered status for the peregrine falcon (see 50 CFR 21.28). Depending on the biological status, States generally list peregrine falcons as endangered, threatened, critically imperiled or as a species of concern. Currently, the peregrine falcon is State-listed in 38 of the 40 States that have nesting pairs. The two States that do not have the species listed—Colorado and Arizona—removed the peregrine falcon from their lists due to its recovery in those States. However, both will continue to regulate take for falconry and other purposes. In many States, falconry is administered cooperatively by the Service and the States.

E. Other Natural or Manmade Factors Affecting Its Continued Existence

Egg collecting, shooting, harvest for falconry, habitat destruction, climate change, and the extinction of passenger pigeons were all considered as possible factors causing or contributing to the decline in peregrine falcon populations in North America; however, no evidence supports any of these factors as causing the widespread reproductive failure and population decline that occurred. In contrast, an overwhelming body of evidence has accumulated showing that organochlorine pesticides affected survival and reproductive performance sufficiently to cause the decline. There currently is no question within the scientific community that contamination with organochlorines was the principal cause for the drastic declines and extirpations in peregrine falcon populations that took place in most parts of North America (Kiff 1988).

Although the use of all organochlorine pesticides causing reproductive failure in peregrine falcons was restricted in the United States and Canada in the early 1970s, their use continues in some areas of Latin America. It was shown, by comparing blood samples collected during fall and spring migration, that migrant peregrine falcons accumulate organochlorines while wintering in Latin America (Henny *et al.* 1982). Henny *et al.* (1996) demonstrated that DDE residues in the blood taken from female peregrine falcons captured during spring migration at Padre Island, Texas decreased between 1978 and 1994. In second-year peregrines, residues dropped from 1.43 ppm between 1978 and 1979 to only 0.25 ppm in 1994 and from 0.88 to 0.41 ppm for older peregrines; these levels are well below those that would affect reproduction (Henny *et al.* 1996).

The widespread reproductive failure and population decline of peregrine

falcons in North America coincided with the period of heavy organochlorine use in the United States. Although there was not an immediate lowering of pesticide residues in eggs following restrictions on the use of organochlorines north of Mexico (Enderson *et al.* 1995), residues gradually declined following the restrictions (Ambrose *et al.* 1988b; Enderson *et al.* 1988; Peakall *et al.* 1990), and most surviving populations began to increase in size thereafter. Despite the continued use of organochlorines in Latin America, populations of American peregrine falcons in North America have recovered substantially in recent years. In fact, Arctic peregrine falcons that winter predominantly in Latin America recovered to the point that the subspecies was removed from the Federal List of Threatened and Endangered Wildlife on October 4, 1994 (59 FR 50796).

Additionally, some of the avian prey used during the nesting season by peregrine falcons throughout North America also winter in Latin America. Many of these prey return to their nesting areas with pesticide residues accumulated during the winter (Fyfe *et al.* 1990). Peregrine falcons preying upon these birds during the summer are further exposed to Latin American pesticides. Overall, pesticide use in Latin America does not appear to have adversely affected reproductive success in American peregrine falcon populations in North America.

We recognize that certain populations of American peregrine falcons have recovered to a lesser degree, and that in some of these populations organochlorine residues are still high and reproductive rates remain lower than normal. Populations on the Channel Islands off southern California are still affected by high organochlorine residues and eggshell thinning (Jarman 1994). This is a localized threat, and the result of using offshore islands as DDT disposal areas during the 1940s. Despite the residual effects of organochlorines on the Channel Islands, this population is continuing to increase, although some of the increase could be the result of the release of a significant number of captive-bred young or dispersal from other areas where recovery is greater (B. Walton, pers. comm. 1997). Based on published values in the literature, detected concentrations of DDT in peregrine falcon eggs collected in New Jersey were sufficient to impact reproduction. Productivity and eggshell thinning data, however, did not support a conclusion of reproductive impairment due to DDT contamination (U.S. Fish and Wildlife Service and New Jersey Department of Environmental Protection 1997). Jarman (1994) suggested that these locally higher egg residues result from a local source of DDT or DDE. As a result, the effects are localized, and the observations do not reflect the current status of peregrine falcons as a whole. In recent years, numbers of peregrine falcons have increased significantly throughout their historical range despite the effects of localized organochlorine residues.

Similarly, American peregrine falcons in southwest Canada have not recovered as well as in most other regions of North America. Despite the release of several hundred captive-bred young in the prairie Provinces and western Canada (Holroyd and Banasch 1990), the number of pairs occupying territories is still well below the number of known historical nest sites (G. Holroyd, *in litt.* 1993). In southern Canada, including the prairie region, the proportion of reintroduced young that entered the breeding population was considerably lower than in the United States (Peakall 1990; Enderson *et al.* 1995). The factor or factors causing this lower recruitment rate remain unknown, but survivorship of peregrine falcons released into this area may be lower than in adjacent portions of the subspecies' range. Pesticide residues in American peregrine falcon eggs do not appear to be higher in southwest Canada than in the United States (Peakall *et al.* 1990). Therefore, higher residual organochlorine contamination is apparently not responsible, and the number of pairs occupying this region continues to increase.

Exposure to organochlorine pesticides caused drastic population declines in peregrine falcons. Following restrictions on the use of organochlorines in the United States and Canada, residues in eggs declined and reproduction rates improved. Improved reproduction, combined with the release of thousands of captive-reared young and relocated wild hatchlings, allowed the American peregrine falcon to recover and peregrine falcons to be successfully reestablished in those areas of the historical range from which the species was extirpated. Pesticide residues, reproductive rates, and the rate of recovery have varied among regions within the vast range of this species. In some areas, such as the Channel Islands off the southern coast of California, the lingering effects of DDT have caused reproductive rates to remain low. Local source contamination may even cause continued reproductive problems in the Channel Islands. In southwest Canada, the rate of recovery, or onset of recovery, apparently lagged behind most other areas, but recent trends suggest that historical nest sites will continue to be gradually re-colonized.

The peregrine falcon has recovered throughout its historical range. Although the recovery is slow in a few parts of the historical range, these areas represent a small portion of the species' overall range. Furthermore, evidence collected in recent years shows that a combination of lingering residues of organochlorines in North America and contamination resulting from the continued use of organochlorines in Latin America has not prevented a widespread and substantial recovery of peregrine falcons, as numbers of peregrine falcons continue to increase. We conclude, therefore, that the continued existence of the American peregrine falcon is no longer threatened by exposure to organochlorine pesticides.

In summary, due to the reduction in the effects of pesticides and widespread positive trends in population size, we have determined that the American peregrine falcon has recovered and is no longer endangered with extinction, or likely to become endangered within the foreseeable future throughout all or a significant portion of its range. We considered the alternative of downlisting the species, but recent data show improvements in breeding pair numbers and productivity, demonstrating that the delisting goals set for the American peregrine falcon in recovery plans were met or exceeded. We believe this available information supports the full delisting of the species throughout its range. Therefore, we are removing the peregrine falcon from the Federal List of Endangered and Threatened Wildlife, thus, removing endangered status for the American peregrine falcon throughout its range, and the similarity of appearance provision for all free-flying peregrine falcons within the 48 conterminous United States.

In accordance with 5 U.S.C. 553(d), we have determined that this rule relieves an existing restriction and good cause exists to make the effective date of this rule immediate. Delay in implementation of this delisting would cost government agencies staff time and monies conducting formal section 7 consultation on actions which may affect species no longer in need of the protections under the Act. Relieving the existing restriction associated with this listed species will enable Federal agencies to minimize any further delays in project planning and implementation for actions that may affect peregrine falcons.

Effects of This Rule

This final rule will affect the protection afforded to North American peregrine falcons under the Act. It will not affect the status of the Eurasian peregrine falcon (*F. p. peregrinus*), currently listed under the Act as endangered wherever it occurs. The endangered designation under the Act for the American peregrine falcon will be removed and the designation of endangered due to similarity of appearance for all free-flying peregrine falcons found within the 48 conterminous United States, including the Arctic and Peale's peregrine falcons, and the reestablished eastern and midwestern populations, will be removed. Therefore, taking, interstate commerce, import, and export of North American peregrine falcons will no longer be prohibited under the Act. In addition, Federal agencies will no longer be required to consult with the Service under section 7 of the Act in the event activities they authorize, fund or carry out adversely affect peregrine falcons. However, as previously discussed, removal of the protection of the Act will not affect the protection afforded all peregrine falcons under the MBTA.

The take and use of peregrine falcons must comply with appropriate State regulations. State regulations applying to falconry vary among States and are subject to change over time. The applicable State regulations may be more but not less restrictive than Federal regulations.

This rule will not affect the peregrine falcon's Appendix I status under CITES, and CITES permits will still be required to import and export peregrine falcons to and from the United States. CITES permits will not be granted if the export will be detrimental to the survival of the species or if the falcon was not legally acquired.

Critical Habitat

Critical habitat for the American peregrine falcon includes five areas in northern California (50 CFR 17.95). The Act defines critical habitat as ''specific areas within the geographical area occupied by the species, at the time it is listed on which are found those physical or biological features essential to the conservation of the species and which may require special management considerations or protection.'' Since critical habitat can be designated only for species listed as endangered or threatened under the Act, all currently designated American peregrine falcon critical habitat will be removed upon publication of this final rule.

Monitoring

Section 4(g)(1) of the Act requires us to monitor a species for at least 5 years after delisting. A monitoring plan was provided in the proposed delisting rule on August 26, 1998 (63 FR 45446). We are currently developing a revised monitoring plan which will be made available for public review in the **Federal Register** in the near future.

Take for Falconry and Other Purposes

Wild American and Arctic peregrine falcons were unavailable for falconry and raptor propagation in the contiguous United States since these two subspecies of peregrine falcons were listed under the Act in 1970. In Alaska, the Arctic peregrine became available for take in 1994 when it was delisted, but take of this subspecies was still restricted in the contiguous United States pursuant to the similarity of appearance provision of the Act. Take of Peale's peregrines also was restricted in the contiguous United States since 1984 pursuant to the similarity of appearance provisions of the Act.

With this delisting, which removes protection of the Act, regulation and management of peregrine falcons in the United States will fall primarily under the MBTA and State regulations. In anticipation of delisting, we are working with the State wildlife agencies to develop draft biological criteria for management of take of peregrines. These criteria will serve as the basis for discussions with authorities in Canada and Greenland to identify appropriate limits for take of passage birds. We will then prepare environmental assessments on the management of nestlings and passage birds and solicit public comment. The resulting management plans will include biological criteria for harvest, implementation criteria, and procedures for evaluating the harvest. One objective of the plans is to allow a level of take that does not compromise continuing restoration of peregrine falcons in North America. We expect to complete the management plan for nestlings by the Spring of 2000, and the management plan for passage birds by the Fall of 2000. Take of peregrine falcons in the conterminous United States is not permitted under the MBTA until the management plans undergo public review and are finalized, approved, and published in the **Federal Register**. Some permit exceptions may be made for scientific research. In Alaska, take of American peregrine falcons is not permitted but take of Peale's and Arctic peregrines may be authorized.

Executive Order 12866

This rule was not reviewed by the Office of Management and Budget under Executive Order 12866.

Paperwork Reduction Act

Office of Management and Budget (OMB) regulations at 5 CFR 1320, which implement provisions of the Paperwork Reduction Act, require that interested members of the public and affected agencies have an opportunity to comment on agency information collection and recordkeeping activities (see 5 CFR 1320.8(d)). We cannot conduct or sponsor, and a person is not required to respond to a collection of information, unless we are in possession of a current OMB Control Number. We intend to collect information from the public during the post-delisting monitoring period. A description of the information that will be collected was provided in the proposed delisting rule. We are revising the monitoring plan that was described in the proposed delisting rule, and will obtain a revised OMB Control Number for, and request public comment on, the revised monitoring plan in the **Federal Register** in the near future.

National Environmental Policy Act

We have determined that an environmental assessment or environmental impact statement, as defined under the authority of the National Environmental Policy Act of 1969, need not be prepared in connection with regulations adopted pursuant to section 4(a) of the Endangered Species Act of 1973, as amended. We published a notice outlining our reasons for this determination in the **Federal Register** on October 25, 1983 (48 FR 49244).

List of Subjects in 50 CFR Part 17

Endangered and threatened species, Exports, Imports, Reporting and recordkeeping requirements, Transportation.

Regulation Promulgation

For the reasons set out in the preamble, we hereby amend part 17, subchapter B of chapter I, Title 50 of the

Code of Federal Regulations, as set forth below:

PART 17—[AMENDED]

1. The authority citation for part 17 continues to read as follows:

Authority: 16 U.S.C. 1361–1407; 16 U.S.C. 1531–1544; 16 U.S.C. 4201–4245; Pub. L. 99–625, 100 Stat. 3500; unless otherwise noted.

§ 17.11 [Amended]

2. Section 17.11(h) is amended by removing the entries for ''Falcon, American peregrine, *Falco peregrinus anatum*'' and ''Falcon, peregrine, *Falco peregrinus*'' under ''BIRDS'' from the List of Endangered and Threatened Wildlife.

§ 17.95 [Amended]

3. Section 17.95(b) is amended by removing the critical habitat entry for ''American Peregrine Falcon.''

Dated: August 17, 1999.

Jamie Rappaport Clark,

Director, U. S. Fish and Wildlife Service.

Subject: **Texas Historical Commission Review – McCombs Landfill**

Dear Mr. Wolfe:

On behalf of the City of El Paso (City), SAIC Energy, Environment and Infrastructure, LLC (SAIC) requests a consultation under Section 106 of the National Historic Preservation Act and the Antiquities Code of Texas for the City's McCombs Landfill (Landfill) in El Paso, Texas. A Request for a State Historical Preservation Officer (SHPO) Consultation Form and any additional required information is provided as an attachment to this letter for your review.

Please do not hesitate to contact Scott Pasternak at (512) 651-6405 with any questions or clarifications regarding this Texas Historical Commission review.

Sincerely,

SAIC Energy, Environment & Infrastructure, LLC

Scott Pasternak
Senior Project Manager

TEXAS HISTORICAL COMMISSION

REQUEST FOR SHPO CONSULTATION:
Projects Subject to Section 106 of the National Historic Preservation Act and/or the Antiquities Code of Texas

Submission of this form only initiates consultation with the Texas Historical Commission, the State Historic Preservation Officer (SHPO) for Texas. The SHPO may require additional information to complete the review for some projects.

FCC projects: this form should not be completed when submitting Form 620 or 621 for communications towers.

Section 106 of the National Historic Preservation Act of 1966, as amended, requires federal agencies to consider the effects of their undertakings on historic properties and to consult with the State Historic Preservation Officer (SHPO) regarding the undertaking. An undertaking is any action by or on behalf of a federal agency that has the potential to affect historic resources and includes funding, permits, or other approvals. Federal agencies are required to identify historic resources that may be affected and to avoid, minimize, or mitigate any adverse effects. The Section 106 regulations are codified in 36 CFR 800 and are available from the Advisory Council on Historic Preservation website at www.achp.gov. Regulations allow 30 days upon receipt for SHPO review.

The Antiquities Code of Texas (Title 9, Chapter 191 of the Texas Natural Resources Code) is intended to protect historic and archeological landmarks and is applicable to public lands owned by the state of Texas or a political subdivision of the state, including state agencies, counties, cities, school districts, and public colleges and universities, as well as other public authorities. Notification of the Texas Historical Commission is required before breaking ground at a project location on state or local public land.

Complete only the first page of this form and add any new information, including attachments.

1. Project Information

PROJECT NAME
City of El Paso McCombs Landfill - Texas Historical Commission Review

PROJECT ADDRESS	PROJECT CITY	PROJECT ZIP CODE(S)
13660 McCombs Road	El Paso	79934

PROJECT COUNTY OR COUNTIES
El Paso

PROJECT TYPE (Check all that apply)

☐ Road/Highway Construction or Improvement	☐ Repair, Rehabilitation or Renovation of Structure(s)
☐ Site Excavation	☐ Addition to Existing Structure(s)
☐ Utilities & Infrastructure	☐ Demolition or Relocation of Existing Structure(s)
☐ New Construction	☒ None of these

BRIEF PROJECT SUMMARY: Please provide a one or two sentence description to explain the project. More details will be provided separately in Part 5, the Project Work Description Attachment.

The City of El Paso proposes to vertically expand the existing McCombs Landfill from the current maximum elevation of 4125' MSL to 4300 'MSL. No lateral expansion is proposed in the permit amendment.

EMAIL

RCarmich@tceq.state.tx.us

Will this project involve public land owned by the State of Texas or a political subdivision of the state? (State Agency, County, City, School District, Public Authority, Public College or University, etc.)

☒ Yes ☐ No

CURRENT OR FUTURE OWNER OF THE PUBLIC LAND

The City of El Paso currently owns the land permitted for the City of El Paso McCombs Landfill.

5. Project Work Description

Attach a detailed written description of the project that fully explains what will be constructed, altered, or demolished. Include architectural or engineering plans, site plans, specifications, or NEPA documents, as necessary, to illustrate the project.

6. Identification of Project Location and Area of Potential Effect (APE)

The APE includes the entire area within which historic properties could be affected by the project. This includes all areas of construction, demolition, and ground disturbance (direct effects) and the broader surrounding area that might experience visual or other effects from the project (indirect effects).

1. **Attach** map(s) indicating the location and specific boundaries of the project. Road names must be included and legible. Identify the project location, boundaries, and APE on the map(s) as precisely as possible. Suggested maps may include USGS 7.5 minute quadrangle maps (or relevant portions thereof), tax maps, satellite images, etc. The number and types of map(s) will depend on the nature and complexity of the project as well as the extent of the APE. **Projects involving ground disturbance must include the appropriate 7.5 minute USGS quadrangle.**
2. **Attach** a brief written description of the APE, including a discussion of the potential for direct and indirect effects that might result from the project and the justification for the boundaries chosen for the APE.

PROJECT NAME

City of El Paso McCombs Landfill - Texas Historical Commission Review

7. Identification of Historic Properties within the APE (Attach additional materials as necessary)

A. Archeological Resources

Does this project involve ground-disturbing activity?

☒ Yes (Please complete this section) ☐ No (Skip to Structures section)

Describe the nature, width, length, and depth of the proposed ground-disturbing activity.

This project involves excavating landfill waste cells to currently permitted depths. The proposed permit amendment does not involve increasing the depth of excavation.

Describe previous land use and disturbances.

The land permitted for the McCombs Landfill has been used for waste disposal activities since the site was permitted in 1984.

Describe the current land use and conditions.

In Texas, the land immediately surrounding and including the McCombs Landfill is predominantly owned by the City of El Paso and is zoned for industrial use or as a ranch or farm district. The land in neighboring New Mexico is predominantly undeveloped and is zoned as a Performance District, used to allow flexibility for land use activities in rural areas.

B. Structures

Are there any structures, buildings, or designed landscape features (park, cemetery, etc.) 45 years old or older within the project area or APE?

☐ Yes ☒ No

Is the project located within or adjacent to a district that is listed in or eligible for the National Register of Historic Places? Eligible districts may include locally designated districts or areas identified in historic resource surveys.

☐ Yes, name of district: ☐ No ☒ Do not know

If the Texas Historic Sites Atlas (http://atlas.thc.state.tx.us) has been consulted, were previously identified architectural resources identified within the project area or APE?

☐ Yes ☒ No ☐ Did not consult Atlas

If the answer to any of the above questions is yes, use the space below or provide an attachment indentifying each structure, building, designed landscape feature, or district within the APE that is 45 years old or older. Include an actual or estimated date of construction and the location of each of the features.

Does the project involve the rehabilitation, alteration, removal, or demolition of any structure, building, designed landscape feature, or district that is 45 years old or older?

☐ Yes ☒ No

If yes, include information with the attachments for Part 5: Project Work Description and Part 8: Photographs.

8. Photographs

Attach clear, high-resolution color photographs that illustrate the project area and APE as defined in Section 6. Images from the internet are not acceptable due to low resolution. Photography should document the project area and properties within the APE, including clear views of any buildings or structures. Please number and label all photographs, and include a map or site plan labeled to show the location and direction of each view. Where applicable, include photographs of the surrounding area from the project site and streetscape images. Should your project entail the alteration of existing structures, please also provide photographs of the existing conditions of sites, buildings, and exterior and interior areas to be affected.

9. Consulting Parties/Public Notification (Section 106 only)

Attach a description of the actions taken to notify the public or invite consultation with parties other than SHPO. Provide a summary of any consultation and comments received from consulting parties or the public.

The SHPO is only one consulting party under Section 106. Refer to 36 CFR 800.2 for information about other participants who are entitled to comment on the Section 106 process, including Native American tribes, interested parties, and the public. Consultation with the SHPO is not a substitution for consultation with Native American tribes. When identifying historic resources within the APE and determining the effect of an undertaking, applicants should consider consulting with the county historical commission and the local historic preservation officer, if any.

10. Applicant's Determination of Effect (Section 106 only)

An effect occurs when an action alters the characteristics of a property that qualify it for listing in the National Register of Historic Places, including changes to the property's location, design, setting, materials, workmanship, feeling, and association. Effects can be direct or indirect, and can be physical, visual, audible, or economic. They may include a change in ownership or change in use.

- ■ **No Historic Properties Affected** based on 36 CFR 800.4(d)(1). Please provide the basis for this determination.
- ☐ **No Adverse Effect** on historic properties based on 36 CFR 800.5(b). Please explain why the criteria of adverse effect at 36 CFR 800.5(a)(1) were not found to be applicable for your project.
- ☐ **Adverse Effect** on historic properties based on 36 CFR 800.5(d)(2). Please explain why the criteria of adverse effect at 36 CFR 800.5(a)(1) were found to be applicable to your project. You may also wish to include an explanation of how these adverse effects might be avoided, minimized, or mitigated.

In the space below or as an attachment, please explain the effect of the project on historic properties.

No historical properties are directly affected with the implementation of the vertical expansion at the McCombs Landfill due to the fact that no previously-undisturbed earth will be added to the waste footprint.

5. Project Work Description

The City of El Paso (City) owns and operates the McCombs Landfill (Landfill) which is managed under Texas Commission on Environmental Quality (TCEQ) Municipal Solid Waste (MSW) permit 729A. The Landfill is located in El Paso County within the El Paso city limits and serves the waste needs of the City and the surrounding area.

In August of 2010, the City voted to implement flow control, a mandate to dispose of all waste generated within the City's jurisdictional area at City facilities. SAIC expects this legislation to increase the throughput to each of the City's landfills by approximately 525,000 Tons Per Year (TPY) in the first year of implementation. The City intends to undergo a vertical expansion of the McCombs Landfill to accommodate the anticipated increase in throughput for the solid waste stream.

The proposed vertical expansion will increase the height of the landfill from the currently permitted elevation of 4,125 feet MSL to 4,305 feet MSL. It is important to note that the proposed expansion will not include any previously undisturbed land as part of the waste footprint. Furthermore, the project involves increasing the above-ground height of the landfill and does not involve deeper excavation of the currently permitted waste cells.

The proposed landfill completion drawings are included as Attachment 2.

6. Identification of Project Location and Area of Potential Effect (APE)

A 7.5 minute USGS quadrangle map of the APE is included as Attachment 3. This map has been prepared to meet the standards of 30 TAC §330.61(e) and depicts a 1-mile radius of influence surrounding the Landfill as the Area of Potential Effect (APE). This radius has been chosen for consistency with the Impact on Surrounding Area report that is required by the TCEQ for the Major Permit Amendment effort.

8. Photographs

A series of aerial photographs showing the existing conditions of the landfill and the surrounding area are provided in Attachment 4.

9. Consulting Parties/Public Notification

Public notification will be required for the McCombs Major Permit Amendment. As per the requirements set forth in 30 TAC §330.69, The City of El Paso will provide notice of the opportunity to request a public meeting and will post notice signs no later than 45 days of the TCEQ executive director's receipt of the application in accordance

with the procedures contained in 30 TAC §39.501. If applicable, notice of a public meeting shall be provided as specified in 30 TAC §39.501(e)(3) and (4).

Furthermore, because the school system closest to the Landfill is required by the Texas Education Code to provide a bilingual program, the City of El Paso will provide public notification in both English and Spanish.

Subject: **Texas Historical Commission Review – McCombs Landfill**

Dear Mr. Wolfe:

On behalf of the City of El Paso (City), SAIC Energy, Environment and Infrastructure, LLC (SAIC) requests a consultation under Section 106 of the National Historic Preservation Act and the Antiquities Code of Texas for the City's McCombs Landfill (Landfill) in El Paso, Texas. A Request for a State Historical Preservation Officer (SHPO) Consultation Form and any additional required information is provided as an attachment to this letter for your review.

Please do not hesitate to contact Scott Pasternak at (512) 651-6405 with any questions or clarifications regarding this Texas Historical Commission review.

Sincerely,

SAIC Energy, Environment & Infrastructure, LLC

Ms. Christine Bergren
MSW Section Manager
Waste Permits Division- MC 124
Texas Commission on Environmental Quality
12100 Park 35 circle
Austin, Texas 78753

Subject: Review of Conformance to the Regional Solid Waste Management Plan for the McCombs Municipal Landfill
MSW Permit Amendment No. 729A

Dear Ms. Bergren,

As required under the Texas Administrative Code Subchapter E § 330.61(p) the Rio Grande Council of Governments has reviewed the permit amendment application for the McCombs Municipal Landfill. On the 19th of October 2011, the Solid Waste Advisory Committee reviewed the permit amendment application for the McCombs Landfill, MSW Permit Amendment No. 729A. The findings from this review are that the permit application conforms to the Regional Solid Waste Management Plan. The recommendations made by the Solid Waste Advisory Committee were approved by the Rio Grande Council of Governments Board of Directors on the 20th of January 2012.

The Rio Grande Council of Governments has not included a review of land use compatibility conformance. As stated in the Regional Solid Waste Management Plan, this review is left to the communities except on those occasions when the Rio Grande Council of Governments is specifically asked to assist in this evaluation. The City of El Paso has expressed no concerns with the land use compatibility of this facility. The Rio Grande Council of Governments will support the local decision of the community.

Should you require any additional information please contact Korina Navarro, the Environmental Services Coordinator at 915-533-0998, ext. 121.

Sincerely,

Judge Veronica Escobar
President, Board of Directors

Att.: Conformance Checklist

September 22, 2011

Ms. Korina Navarro
Environmental Services Coordinator
Rio Grande Council of Governments
1100 N. Stanton, Suite 610
El Paso, Texas 79902

Subject: **Solid Waste Conformance Checklist for McCombs Municipal Landfill**

Dear Ms. Navarro:

The City of El Paso (City) is pleased to submit this solid waste conformance checklist and packet for the City's McCombs Municipal Landfill (Landfill). The City, with assistance from SAIC Energy, Environment and Infrastructure, LLC (SAIC), is preparing Major Permit Amendment #729A (MPA) application for submittal to the Texas Commission on Environmental Quality (TCEQ). This submittal contains the information requested on the checklist. The City, and by extension, the Landfill will support and conform to the goals of the Rio Grande Council of Governments (RGCOG). The City will specifically support the goals listed on the conformance checklist (Goals 1 and 3 from the Regional Solid Waste Management Plan (RSWMP)) in the following manner:

- **Goal 1 – Promote planning to ensure adequate services and facilities for the proper management and disposal of municipal solid waste:** The City is open to participating in public/private partnerships to share the cost burden of clean-up events and currently partners with Keep El Paso Beautiful and other non-profit entities on community events by providing roll-off containers, bulk waste pickup, scrap tire disposal, and/or waived or reduced landfill tipping fees.

Carl L. Robinson

District 5
Dr. Michiel R. Noe

District 6
Eddie Holguin Jr.

District 7
Steve Ortega

District 8
Cortney Carlisle Niland

City Manager
Joyce A. Wilson

- **Goal 3 – Reduce the amount of municipal solid waste disposed of, through waste reduction, recycling, and reuse:** The Landfill has plans in place to divert white goods, tires, yard waste, brush and scrap metal. Additionally, the City will be implementing a mulching program at the landfill to further reduce the net volume of brush disposed at the Landfill. Mulch will with used for City projects and remaining mulch will be offered to the public.

In addition, while RGCOG has not specifically included Goal 2 from the RSWMP as a part of the conformance checklist, this proposed vertical expansion will support this goal to provide technical support and services to promote local and regional municipal solid waste planning. The proposed vertical expansion will support this goal by ensuring long-term disposal capacity in the solid waste system by extending the Landfill's site life by approximately 30 years. The Landfill is an integral part of the regional solid waste system, and currently represents approximately 35 percent of the available disposal capacity for the region, according to the 2010 Annual Reports submitted to the TCEQ.

The City is also providing the requested contact information for the Applicant, the Applicant's Engineer and the TCEQ.

RIO GRANDE COUNCIL OF GOVERNMENTS
SOLID WASTE PLAN CONFORMANCE CHECKLIST

All applicants seeking a MSW facility permit or registration are required to demonstrate conformance to the Regional Solid Waste Management Plan by the Texas Commission on Environmental Quality (TCEQ). The Texas Administrative Code Subchapter B § 330.61(p) states that the owner or operator shall submit documentation that Parts I and II of the application were submitted for review to the applicable council of governments for compliance with the Regional Solid Waste Plan.

The Solid Waste Advisory Committee (SWAC) will review the application based on the following checklist. These questions will provide the SWAC with information on how the proposed facility will support the goals and objections of the Plan. All questions must be answered entirely in order for the SWAC to review the proposal. Incomplete questionnaires will be returned to applicants. The certification box must be signed by the chief administrative officer of the applicant, indicating that all information provided is accurate and truthful.

Instructions:

To request a conformance review of a MSW registration or permit application, the following information must be submitted to the Rio Grande Council of Council (RGCOG):

1. Copy of the Application to the TCEQ, Parts I and II.
2. Solid Waste Plan Conformance Checklist (attached)
3. A cover letter with contact information for the applicant, the applicant's engineer and the TCEQ staff person to whom all review-related correspondence should be sent. Contact information should include name, phone number, mailing address, and email address (if available).
4. A map showing the physical location of proposed or existing facility.
5. Any additional information the applicant wishes to provide to facilitate the SWAC review process.

All documents and information should be submitted to the following address:

Environmental Services Coordinator
Rio Grande Council of Governments
1100 N. Stanton, Suite 610
El Paso, TX 79902

RIO GRANDE COUNCIL OF GOVERNMENTS
SOLID WASTE PLAN CONFORMANCE CHECKLIST

Section 1: General Applicant Information

1.1 Applicant's Name: McCombs Municipal Landfill

1.2 Location of proposed facility
Nearest City: El Paso, Texas County: El Paso

1.3 ☐ New facility or ☒ Amendment to current permit/registration

1.4 Is this a permit or a registration application?
☒ Permit No.729A ☐ Registration No._____

1.5 What type of MSW facility is being registered or permitted?
☒ Type I Landfill
☐ Type I AE Landfill
☐ Type IV Landfill
☐ Type IV AE Landfill
☐ Type V Facility
☐ Other (please describe)
Describe "Other" below:

1.6 What types of waste(s) will be accepted at your facility?
Municipal Solid Waste, Class II Industrial Waste, Construction and Demolition, Regulated Asbestos Containing Material

1.7 Do you currently or plan to accept special or industrial waste? If so, which classes?
Class II Industrial Waste and Regulated Asbestos Containing Material

1.8 Do you currently or do you plan on accepting treatment plant sludge, treated septage or any other potentially odorous wastes?
Yes, any liquid wastes that are dewatered and will pass the paint filter test can be accepted at the facility. No liquid waste will be accepted.

1.9 What entity or entities in the RGCOG Region is this facility intended to serve?
City of El Paso area; El Paso County, Texas; Doña Ana County, New Mexico

1.10 Does your facility have an operating or host agreement with any RGCOG entity or entities? If so, please provide. If not, do you plan to enter into one?
No operating or host agreement and no intentions to enter into one.

1.11 If the proposed facility is other than a landfill, where will the stored or processed wastes be taken for disposal?
N/A

Section 2: Regional Goal Conformance

Please provide information as to how your proposed facility will help to support or conform with the goals and objectives of RGCOG's Regional Solid Waste Management Plan.

Community Clean-Up Events & Illegal Dumping:

Goal 1: Promote planning to ensure adequate services and facilities for the proper management and disposal of municipal solid waste.

2.1.1 Do you plan to participate in any public/private partnerships to share the cost burden of clean-up events?

☐ Yes ☒ No

If yes, please describe:

The City is open to participating in public/private partnerships to share the cost burden, but no partnerships have been established. The City partners with non-profit entities including Keep El Paso Beautiful and Home Owners Associations on community clean-up events.

2.1.2 Do you plan to provide sponsorship for community clean-up events? (e.g., provide roll-off containers at no cost or at significantly reduced costs?)

☒ Yes ☐ No

If yes, please describe:

The City partners with HOAs and Keep El Paso Beautiful on community clean-up events by providing roll-off containers, bulk waste pickup, scrap tire disposal, and/or waived or reduced landfill tipping fees.

2.1.3 What measures do you plan to take to make your facility accessible to the general public? (e.g., operational hours that are public-friendly, extended daytime hours and/or weekend hours, posted fee scales, map availability, public advertising methods, etc.)

The landfill will offer operating hours from 7 am to 4 pm six days a week (Monday – Saturday). Operating hours and landfill tipping fees are posted at the site entrance and on the City's website. Public advertising in the form of press releases is made to inform the public of news events and any changes to the operations.

2.1.4 What plans do you have to help curtail illegal dumping in the vicinity of the proposed facility?

Posted signage outside the landfill informs the public that illegal dumping is a crime and

is not allowed. A security company patrols the landfill as a means of guarding the property and discouraging illegal dumping. Also, a security camera system will be installed to monitor the property and curtail illegal dumping.

2.1.5 As part of your operating plan, will you accept waste from locally sponsored litter and illegal dumping clean-up projects at no cost or at significantly reduced costs?

☒ Yes ☐ No

If yes, please explain:

Yes, the City participates in community clean-up events and accepts waste from locally sponsored cleanups at no cost or at reduced landfill tipping fees.

Recycling:

Goal 3: Reduce the amount of municipal solid waste disposed of, through waste reduction, recycling, and reuse.

2.2.1 If applicable, how will your facility manage scrap/used tires? Please explain in detail.

Whole used or scrap tires are accepted at the landfill and stored in a dedicated trailer for disposal off-site. Customers entering the landfill are questioned if they are bringing tires for disposal. Tires are placed in the tire trailer, and the tire trailer is transported off-site to the City's contracted Vendor for disposal. A manifest is prepared for each shipment to include the date/time, unit #, generator name & signature, driver name and signature. The tire trailer is weighed prior to leaving the site to document the weight. The manifest is completed at the point of disposal and returned to the landfill.

2.2.2 What are your plans for managing yard waste and brush? Please explain in detail.

The City will be implementing a mulching program at the landfill to help reduce the net volume of brush waste disposed at the landfill. A horizontal grinder will be used to grind the yard and brush waste at the landfill. Brush waste received at the City's Citizen Collection Stations will be transported to the landfill where it will be mulched. Mulch will be used for City projects and any remaining mulch will be offered to the public. A compost pilot project will be implemented to appropriately design the "recipe" and evaluate the market demand of compost.

2.2.3 Will any of the following items be diverted for recycling or reuse?

- ☐ Electronics
- ☒ White Goods
- ☐ Construction/Demolition Debris
- ☒ Tires
- ☒ Yard waste & brush
- ☒ Scrap Metal
- ☐ Other (please describe)

2.2.4 If the proposed facility is other than a landfill, what, if any, type of measures will be taken to minimize, reduce, or recycle the waste before it is hauled off for disposal?

Not applicable. The proposed facility is a landfill.

Section 3: Certifications

I hereby certify that the information contained herein is, to the best of my knowledge complete and accurate and that the information in fact represents the MSW facility for which this entity is requesting a TCEQ permit or registration.

SAIC®

A Site Development Plan has been provided as Part III of this MPA application submittal as per the regulations set forth in 30 TAC §330.63. The following Section 3.1 provides a narrative which includes the criteria that, in the selection and design of the facility, will provide for the safeguarding of the health, welfare, and physical property of the people and the environment. This is accomplished through consideration of the site geology and soil conditions, drainage, land use, zoning, and adequacy of access roads and highways.

3.1.1 Site History

The Landfill is located approximately 20 miles northeast of downtown El Paso near the intersection of McCombs Road and Stan Roberts (FM 2529). The limits of the facility are approximately defined as McCombs Road to the west, Stan Roberts (FM 2529) to the south, State Highway/County Road 293 to the north, and vacant desert land to the east.

The McCombs Landfill was originally permitted on August 13, 1976 under Permit No. 729 for operation on 25 acres. A permit amendment was issued on May 30, 1984 which increased the total permitted area from 25 acres to 327 acres (327.292 acres in Section 6, Block 80, Township 1, Texas and Pacific Railway Survey, per the site legal description). The facility ceased regular solid waste disposal activities on February 3, 2005 and has only received limited waste since this time from City clean-up projects and storm events. Prior to landfilling operations, the site was owned by Prices Producers, Inc. (Prices). The City of El Paso purchased the property from Prices in September 1954. The site was subsequently leased to El Paso Sand Products to be used for aggregate mining.

Previous landfill activities were confined to approximately 95.2 acres (74.7 acres unlined and 20.5 acres lined (Phase I/II)) of land on the southwest quadrant of the permitted facility as well as existing Sector A (17.4 acres). A paved access road just north of the intersection of McCombs Road and Stan Roberts (FM 2529) provides access to the landfill facility.

3.1.2 Permit Amendment Overview

This MPA application develops a vertical expansion of the Landfill from a current maximum height of 4,125 feet MSL to 4,305 feet MSL. This corresponds to an increase in capacity of 46,468,693 CY from a previously permitted volume of 22,348,549 CY to a new permitted volume of 68,817,242 CY. The expansion will apply to all areas of the landfill, including the previously-filled 95.2 acre area in the southwest corner. 64.0-acres will have a piggyback liner, as described in Section 3.4 and portrayed on drawing P3-28B in Appendix 3G, Attachment 4. 11.5 acres will not

receive liner as they are the sideslopes of the expansion area and will not receive any MSW waste. 20.5 acres (currently Subtitle D lined Phase I/II) will continue to be used for MSW disposal (including RACM disposal as described in Section 4.9.22), but at an increased elevation. The additional acreage between the previous southwest area (95.2-acres) and the new total acreage in the southwest area (96.0-acres)is the acreage that previously existed between the unlined and lined areas (Phase I/II).

This vertical expansion will not involve excavation below the previous permitted elevations for the Landfill.

This MPA also increases the property/facility area from 327.292 acres (as described in Section 3.1.1) to 346.74 acres within Section 6, Block 80, Township 1, Texas and Pacific Railway Survey. An updated metes and bounds is provided in Appendix 1C. It should be noted that the increase is only for the property/facility boundary and the permitted waste footprint size is not increasing.

3.1.3 Geology and Soil Conditions

A detailed discussion of the geology and soil conditions at the Landfill can be found in Appendix 3K – Geology of this MPA application.

The Landfill is located on deposits of the Hueco Bolson, probably Camp Rice Formation. The Camp Rice Formation unconformably overlies the Fort Hancock Formation and is primarily composed of gravel, sand, silt and occasional discontinuous lenses of volcanic ash. The Camp Rice Formation is composed of two basic subdivisions, a fluvial and a piedmont facies. The fluvial facies is chiefly sand to pebbly river-channel deposits with subordinate fine-grained overbank units. This facies thickens toward the bolson axes and commonly wedges out against the piedmont facies. The permitted landfill area is probably underlain by fluvial deposits of the Camp Rice Formation.

The Hueco Bolson deposits primarily consist of clay, sand, and gravel, with some caliche. The landfill site is underlain by Tertiary and Quaternary basin (bolson) deposits, overlain by areas of gravel and caliche rimrock. Recent Quaternary alluvial deposits are also present in the landfill vicinity in topographically low areas.

In general, the relatively clean sand and silty sand are non-plastic, while clayey sand ranges from low to high plasticity. Permeability tests were not considered necessary based on the soil types encountered during the site characterization. Estimated coefficient of permeability are between 0.01 and 0.04 centimeters per second (cm/sec).

3.1.4 Surface Water and Drainage

The complete Facility Surface Water Drainage Report can be found in Section 3.3 of this MPA application submittal.

The stormwater on site is directed away from active portions of the landfill by ditches designed for the 25-year 24-hour storm event. The ditches direct water to the three onsite stormwater retention ponds (A, D, and E). These ponds are designed to hold the 100-year 24-hour storm event as well as contingency storage for sediment.

Four ponds will exist in the final cover condition (A, B, C, and E). Perimeter ditches will be constructed as the intermediate elevations increase above existing grade. These ditches will direct water to the retention ponds where they will retain the 100 year 24-hour event and sediment. The landfill will provide care and management, both during construction and long term, of soil erosion and control of sediment due to surface water.

The care and management of soil erosion and sedimentation is outlined in Appendix 3B – Surface Water Drainage Analysis. The facility will prevent discharge of pollutants to waters of the state. There are no waters of the United States or Corps of Engineers' jurisdictional waters of the state on site therefore no Section 404 permit is required. The McCombs Landfill submitted a notice of intent (NOI) to comply with the TPDES Multi-Sector General Permit relating to stormwater discharge and received Permit No. TXR05L795 from the TCEQ on October 28, 2011. A copy of this permit is included in Appendix 2D – TPDES Multi-Sector General Permit.

3.1.5 Land Use and Zoning

A detailed analysis of the land use and zoning of the area immediately surrounding the Landfill is included in Appendix 2B – Land Use Analysis of this MPA application. As described in this analysis, the Landfill is located within the City limits approximately 10 miles northeast of downtown, and lies within 500 feet of the Texas-New Mexico border.

In Texas, the land surrounding the landfill is predominately zoned for light or heavy industrial use, or as a ranch or farm district. From El Paso county plat records and from a visual survey conducted on November 10, 2010, the land immediately surrounding the landfill is primarily owned by the City and is mostly undeveloped.

In New Mexico, the surrounding land use is zoned as a Performance District (PD). According to the Dona Ana County Land Use Regulations and Zoning Ordinance, the purpose of zoning a region as a PD is to allow flexibility for land use activities in the rural areas of the County by acting as a mixed use zone.

No schools, licensed day-care facilities, churches, hospitals, cemeteries, or lakes were identified through visual survey or parcel records within one mile of the Landfill. One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.

3.1.6 Access Roads and Highways

A traffic impact analysis (TIA) completed by the City of El Paso has been included in Appendix 2C – Traffic Analysis of this MPA application.

The TIA explored the impact of the background traffic growth with the addition of the Landfill traffic to determine the level of mobility (LOM) for McCombs Road, the main access road for the site. As stated in the analysis, McCombs Road between State

3.2.1 Facility Access and Site Security

All public access will be controlled to minimize unauthorized traffic, illegal dumping and exposure to hazardous materials. Access to the Landfill will be restricted by existing barbed wire fencing along the perimeter of the facility as well as a locking gate at the facility entrance. These measures will act as deterrents for unauthorized entry during and outside of normal Landfill operating hours. Existing earthen berms along the western and northern boundaries of the Landfill also act as natural deterrents and provide a method of visual screening. The City will install debris netting as needed along the facility boundary.

During times in which the Landfill is accepting waste, access to the Landfill will be restricted to designated Landfill personnel, approved waste haulers, and citizens who have been properly identified by Landfill personnel. Citizens will be directed to a public drop-off area (PDA) and may only be granted access to the working face under the direction of Landfill staff.

3.2.2 Waste Movement

As noted in Section 2.2.1, the Landfill will accept MSW as defined by 30 TAC §330.3, inert construction and demolition waste (Class 3 like), and several types of special wastes. Special wastes accepted include Class II industrial waste and municipal commercial waste such as treated medical waste, processed grease/grit trap waste, dead animals, slaughterhouse wastes, and petroleum-product or crude oil contaminated soil. The Landfill also intends to accept RACM. The specific procedures for acceptance, processing and disposal of these wastes are described in Part IV – Site Operating Plan of this MPA application submittal.

Drawing P3-1 shows the general waste movement flow chart for the Landfill. As can be seen from this drawing, all waste will enter the Landfill through the site entrance and will be screened and documented by the scale house attendant. The scale house attendant will be knowledgeable in the types of waste that are accepted and not accepted at the Landfill and will direct each waste hauler to the appropriate area for processing and disposal. Landfill personnel will have the authority to reject any waste that cannot be accepted at the facility. Haulers identified as sources of identified prohibited waste will be responsible for removing the prohibited waste from the Landfill.

In the event that unauthorized waste is not discovered until after the waste hauler has left the Landfill, the waste will be separated and controlled as necessary. Landfill personnel will make an effort to identify the source of the unauthorized waste and have the waste hauler return to the site to remove the waste. If a positive identification cannot be achieved, Landfill personnel will notify the TCEQ and seek guidance on

practical disposal of the waste. A record of the removal of unauthorized waste will be kept in the Site Operating Record.

3.2.2.1 Public Drop-Off Area

All residents and some commercial haulers will be directed to the PDA to dispose of wastes in roll-off containers. Trained Landfill personnel will be positioned at the public drop-off area and working face to visually screen for prohibited items.

3.2.2.2 Bulky Items Storage

Customers disposing of bulky items and white goods will be directed towards the public drop-off area for unloading (as identified on Drawing P3-17). Acceptable bulky items and white goods include automobiles, metal tanks, large metal pieces, and household appliances that have had all chlorinated fluorocarbons (CFCs) removed in accordance with 40 CFR §82.156(f). These items will be recycled by a permitted salvage company under contract with the City.

3.2.3 Sanitation and Water Pollution Control

As described in Section 3.3 – Facility Surface Water Drainage Report, the Landfill will retain all stormwater collected from the property in on-site collection ponds. These ponds are designed to hold the runoff from the facility during the 100-year storm event with 25 percent emergency capacity as well as the volume of silt generated from the drainage area.

Stormwater runoff from the covered waste mass (i.e., not active) will be collected in v-ditches around the perimeter of the landfill. These v-ditches are designed to convey the 25-year storm event for each drainage basin and will direct the stormwater runoff into existing stormwater retention ponds. The retention ponds on site do not have an outlet structure and will drain down via infiltration (or evaporation). Stormwater runoff from the active waste mass will be contained with site run-on/runoff berms as described in Appendix 3I and will be treated as leachate.

Containment areas for the public drop-off area are identified on the Moreno Cardenas Drawing C13 (Appendix 3E). Additionally calculations for storage capacity as well as high water and top elevation for the containment ponds are provided on the drawing.

3.2.3.1 Public Drop-Off Area and Bulky Items Storage

Stormwater from the PDA will be conveyed to stormwater retention ponds located in the entrance facility area (Drawing P3-17 in Appendix 3E). Interior roads leading from the entrance of the facility to the grade-separated PDA will be paved using asphalt. The area under the roll-off containers will be paved with concrete. Both the asphalt and the concrete will be sloped to prevent ponding and to encourage the conveyance of water to the stormwater retention ponds.

3.2.4 Endangered Species Protection

Correspondence with the Texas Parks and Wildlife Department and the U.S. Fish and Wildlife Service regarding the identification and protection of endangered and threatened species is provided in Section 2.10 and Appendix 2F. Landfill staff will follow the recommendations specified if a species identified is encountered during excavation or filling operations.

This report has been prepared consistent with the requirements of 30 TAC §330.301-330.307. Included in this report are pre-developed, existing, and developed drainage area maps along with erosion control measures and drainage control features. Also provided are hydrologic calculations for pre-developed, existing and developed Landfill conditions. These calculations demonstrate that there is no significant alteration in drainage patterns due to the development of the Landfill. During all phases of construction, the Facility will be constructed, maintained and operated to ensure that run-on and runoff during the 25-year storm event is controlled within the site.

3.3.1 Drainage Analysis

3.3.1.1 Concepts and Methods

The hydrologic and hydraulic methods employed in this report are consistent with TCEQ regulations. The criterion used is located in the Texas Department of Transportation Bridge Division Hydraulic Design Manual (DOT Drainage Manual). The hydrologic and hydraulic analyses were performed using the Rational Method and Manning's Equation respectively. The Rational Method is based on the maximum flow rate from a drainage area being produced by flows at a given rainfall intensity contributing to the flow at the point of discharge.

The Rational Method equation (in English Units) is as follows:

$Q = CIA$

Where:

Q = Flow rate of Discharge, in cubic feet per second (cfs)

C = Runoff Coefficient, which is unitless

I = Rainfall Intensity, in inches per hour (in/hr)

A = Drainage Area, in acres

The Intensity (I) for a rainstorm is determined from the formula (in English units):

$I = b/[T_c+d)^e]$

Where:

I = Rainfall Intensity, in inches per hour

T_c = Time of Concentration, in minutes (Calculated using the Watershed Lag Method)

e,b,d = Coefficients for specific frequencies, unitless

The runoff coefficient, C, is based on the topography, land cover, and land development of the contributing drainage area. Values of C from the DOT Drainage Manual are shown in Appendix 3B, Attachment 1 – Stormwater Calculations.

The rainfall intensity, I, is based on the time of concentration, T_c, in minutes. This is the time it takes the runoff to flow from the furthest point in the drainage area to the point of discharge.

The coefficients used for El Paso County, as obtained from the DOT Drainage Manual are shown in Appendix 3B, Attachment 1 – Stormwater Calculations.

The 24-hr, 25-yr storm event was used for the design of conveyance facilities and the 24-hr, 100-yr storm event was used for the design of ponding facilities and to check overtopping of conveyance facilities.

The volume of runoff for each drainage sub-basin was found using the NRCS Runoff Curve Number Method as discussed in the DOT Drainage Manual.

The NRCS method is expressed by the following equation (in English units):

$S = (1000/CN)-10$

Where:

S = Potential Maximum Retention (inches)

CN = Curve Number

Runoff Depth is determined from the formula (in English units):

$R = [(P-0.2S)^2]/[P+0.8S]$

Where:

R = Runoff Depth (inches)

P = Precipitation (inches)

A curve number of 68 was used for existing conditions, representing range land conditions. The closed Landfill with the rock armoring was given a conservative curve number of 73 for final developed conditions. The precipitation for the design events as discussed in the DOT drainage manual can be seen Appendix 3B, Attachment 1 – Stormwater Calculations.

3.3.1.2 Existing Conditions

The McCombs Landfill is an existing municipal solid waste disposal facility located in Section 6, Block 80, Township 1, within the city limits of El Paso, at the intersection of McCombs Road and FM 2529 (Stan Roberts Sr. Road). The site covers 347 acres and the surrounding areas are largely undeveloped. Located west of McCombs Road is the Public Service Board - El Paso Water Utilities' Sludge Monofill.

The soils in the Landfill area are predominantly Turney-Berino Association, moderately deep over soft caliche, in the Hueco Bolson. The soils are characterized as moderately permeable, having high water-holding capacity, and having a slow runoff

rate. Caliche covers the entire Bolson surface and ranges in thicknesses of immeasurable to 8 feet thick.

Pre-Developed drainage patterns and flow rates are shown on Drawing P3-3 – Pre-developed Drainage Conditions, in Appendix 3C. This drawing and drainage discharge values are from the permit dated April 2002, by Moreno Cardenas and remain the same in the Permit Modification dated April 2009 by Parkhill, Smith and Cooper, Inc. (PSC). The existing drainage patterns and flow rates are shown on Drawing P3-4 - Existing Drainage Conditions, in Appendix 3C. It should be noted that the existing drainage patterns have been updated to include the 19.4 acre site facilities drainage area.

Stormwater runoff is collected in a v-ditch around the perimeter of the existing Landfill units and is directed into one of the site stormwater ponds. Runoff generated to the north and east of the existing Landfill is captured in the mined pit area. Some of the runoff in the northwest corner continues to the site of existing Retention Pond A. Runoff generated to the west and south of the existing Landfill area is conveyed into existing Retention Pond D (located west of the existing fee house) and existing Retention Pond E (located in the southeastern corner of the developed Landfill area). Stormwater from the 19.4 acre site entrance facilities area (existing conditions) generally flows to natural low lying areas infiltrates.

Intermediate and long term erosion stability of this site will be dependent upon the implementation of both structural and non-structural best management practices (BMPs) which are also discussed in Appendix 3B – Surface Water Drainage Analysis.

3.3.1.3 Developed Conditions

The Final Drainage Conditions plan, provided in Appendix 3C, Drawing P3-6 shows the final developed conditions. The final contours include four ponds to break up drainage areas (the existing Retention Ponds A and E, and Ponds B and C), and in effect reduce sheet flow and minimize erosion. Existing Pond D is no longer needed as that area is filled to grade and flow is conveyed in a v-ditch to Pond E. Also, the final drainage conditions plan for the site entrance facilities area is provided as Drawing C-13 in Appendix 3E. Stormwater from the site entrance facilities area will be contained in one of six onsite detention areas (labeled as DA-1 through DA-6). All runoff from the site will be contained in onsite retention basins.

A total of eight drainage sub-areas are included in the developed drainage conditions plan as shown on Drawing P3-6 - Final Drainage Conditions. Peak flow rates were calculated for each sub-area and are shown on a table within the drawing. Calculations for peak flow rates are included in Appendix 3B, Attachment 1 – Stormwater Calculations.

Stormwater runoff down the side slopes will be captured by a v-ditch, and directed to one of the four ponds. The perimeter drainage system of v-ditches is designed to convey the 25-yr storm event for each drainage basin. All ditches have also been checked to ensure no overtopping occurs in the 100-yr storm event. Calculations for the perimeter ditch designs are provided in Appendix 3B, Attachment 2 – Ditch Calculations. The earthen v-ditches range in depth from 1.71 to 2.26 feet in depth

with 3H:1V side slopes which includes at least 25% depth of freeboard. Velocities in the ditches range from 3.42 to 6.74 feet per second, as shown in Appendix 3B, Attachment 2 – Ditch Calculations. The ditches with velocities exceeding 4.0 feet per second will require erosion protection, according to maximum non-erodible velocities as published in the USDA-SCS Engineering Field Manual, as outlined in a table on the Final Drainage Conditions drawing (Drawing P3-6).

Culverts will be required to convey water from the existing stormwater Retention Pond E to Pond C, as shown on the Final Drainage Conditions drawing. The culverts were sized by Moreno Cardenas using the Heasted Methods Flowmaster program and are provided in Appendix 3B, Attachment 3. The final drainage conditions of the updated closure plan have been evaluated to ensure the culverts sized previously are adequate. The culverts can be seen on the Final Drainage Conditions drawing and the details as provided previously by Moreno Cardenas are provided on Drawings P3-9 and P3-10 in Appendix 3C.

There are two future retention ponds (B and C) and two existing retention ponds (A and E) for the McCombs Landfill final conditions. The ponds are designed to hold the runoff from the 100-yr storm event, 25% emergency capacity, and silt volume (0.012 ac-ft/acre) generated from the drainage area. Pond A is located in the northwest corner of the site within the 100-year floodplain and retains water from drainage areas DEV-2, DEV-3 and DEV-4. See Section 3.3.2 for a discussion of the 100-Year Floodplain area. This area is not regulated under the Section 404 provisions of the Clean Water Act and the Department of the Army permit is not required. A letter from the Department of the Army, date July 2002, is provided in Appendix 3B, Attachment 4. Pond B is located in the northeast corner of the site and retains water from drainage areas DEV-5 and DEV-6, which includes some minimal offsite run-on storm water from just outside the east property boundary. Pond C is located in the southeast corner of the site and retains water from drainage areas DEV-7, DEV-8 and discharge from Pond E, through three 36 inch culverts, which retains water from drainage area DEV-1. The ponds are shown on Drawing P3-6 - Final Drainage Conditions. Calculations for the pond capacities are provided in Appendix 3B, Attachment 1 – Stormwater Calculations. Results of modeling the culverts from the existing pond are provided in Appendix 3B, Attachment 3 – Culvert Calculations.

Developed drainage patterns do not alter the pre-developed and existing conditions in such a way that hinders off-site areas. The perimeter v-ditches and ponding areas will control all runoff generated within the site. The Landfill retains the stormwater onsite as well as accepts some off-site run-on from adjacent properties located to the north, east and south. The off-site run-on is created by visual screening berms that are located approximately 30 feet beyond the property line. All drainage calculations for the facility (both existing and future conditions) include the additional run-on from these off-site areas.

The mined pit area will act as a natural low-lying infiltration basin during interim phases of Landfill operation (applicable to Sectors A through F). The low-lying areas will be graded during Sector construction so that the drainage is away from the developed Sector, preventing run-on. In addition, as each Sector is developed, delineation berms will be placed around the current Sector to prevent runoff from the

working face and run-on from the surrounding features. Retention Ponds B and C will be developed as fill progresses and interim phases are built (Sectors F and D, respectively); Retention Ponds A and E are already constructed. The site retention basins are designed to handle stormwater during all phases of construction (and also for final closure) for any stormwater runoff that leaves the non-active Landfill footprint. The calculations provided for the site retention basins in Appendix 3B, Attachment 6 are for the final closure condition (i.e., the worst case scenario in which the most runoff will be directed to the retention basins); therefore the basins are adequately sized for all phases of Landfill construction. The site drainage collection, conveyance, and detention structures are designed to operate during all phases of Landfill construction so that the existing drainage patterns will not be adversely altered in accordance with 30 TAC §330.305(a). Existing and final stormwater calculations are provided in Appendix 3B, Attachment 6 – Drainage Calculations. Interim structures include delineation (run-on, runoff) berms as identified on Drawing P3-29, Detail 4. Non-erodible velocities and soil loss calculations during all phases of Landfill construction are summarized in Appendix 3B (calculations are provided in Appendix 3B, Attachment 6 and 5, respectively).

3.3.1.4 Erosion and Sedimentation Control Plan

The facility has been designed to prevent discharge of pollutants into waters of the State or waters of the United States, as defined by the Texas Water Code and the Federal Clean Water Act. An Erosion and Sedimentation Control Plan is provided in Appendix 3B. The Landfill supervisor is responsible for maintaining drainage structures to ensure proper working order per the Site Operating Plan maintenance requirements. The Landfill submitted a notice of intent (NOI) to comply with the TPDES Multi-Sector General Permit relating to stormwater discharge and received Permit No. TXR05L795 from the TCEQ on October 28, 2011. A copy of this permit is included in Appendix 2D – TPDES Multi-Sector General Permit.

3.3.2 Flood Control and Analysis

There is an area of the Landfill, including existing Pond A, to the northwest corner that lies in the 100-year floodplain as shown on the Flood Insurance Rate Map (FIRM) Panel No. 480214 0004 C and Appendix 3D, Drawing P3-14 - 100-Year Floodplain Map. The zone designation for the floodplain is A1, which is an area of 100-year flood with already determined base flood elevations (BFE's) and flood hazard factors. The BFE's were converted from NGVD29 Datum to the City of El Paso Datum with a factor provided by Land-Mark Professional Surveying Incorporated. As shown on Drawing P3-8, the BFE's are below the site berms located around the site, and therefore the 100-year flood will be diverted around the Landfill site to the north and will not affect stormwater elevations within Pond A nor will the BFE's affect Landfill operations. The FIRM map is provided in Appendix 3D, Drawing P3-13.

Pond A was sized as described above with a storage capacity of 19.77 ac-ft. The 100-year 24-hour storm event contributes 17.67 ac-ft of runoff volume (including 25% emergency capacity and silt volume of 0.012 ac-ft/yr). Note from the high-water elevation provided on the cross sections, at least three feet of freeboard is provided in

accordance with 30 TAC §330.307(b)(1). Pond A was sized to contain the volume of runoff plus a 25% emergency capacity and silt accumulations thus minimizing the impact to the BFEs for the area. The floodplain does not come into contact with the Landfill operational areas as described above.

3.3.3 Conclusion

The facility has been designed to comply with 30 TAC §330.301 through §330.307.

This waste management unit design plan for the Landfill addresses all weather operation, identifies the method used for landfilling, identifies the deepest excavation, estimates the waste deposition rate, projects site life, provides cross sections of the Landfill, provides a liner quality control plan, and provides a final cover quality control plan.

3.4.1 Landfill Unit Design

3.4.1.1 Provisions for All-Weather Operation

30 TAC §330.63(d)(4)(A)

Precautions will be taken to ensure all roads are passable during all weather conditions. New all-weather roads will be constructed as fill progresses in each area of the Landfill. The roads will consist of a compacted layer on the road surface to minimize mud tracking and allow access during all weather conditions. The main access road to the site will be constructed with a top layer of flexible pavement.

3.4.1.2 Proposed Landfill Method

30 TAC §330.63(d)(4)(B)

The McCombs Landfill has broken up development into eleven sectors. These sectors are identified as A through K. Drawings depicting this layout, existing site conditions, final fill height, drainage structures, and entrance facilities are provided in Appendix 3E - Site Layout Plans. Area filling will take place in each sector before moving onto the next. The settlement rate will be affected by the method of landfilling, the amount of moisture in the refuse, and by the amount of compaction received. Poor compaction and high lifts would result in more settlement. Decomposition is anticipated to be slow due to the low amount of precipitation received on average in the area. An in-place density of 1,200 pounds per cubic yard (lb/cy) or greater will reduce the amount of settlement.

Excavation side slopes and final side slopes will be no steeper than 3H:1V, and the final top slope will be approximately 7%. Placement of final cover will generally follow the same sequence of development, sector A through K. Closure of each sector will be in accordance with the closure plan provided in Section 3.8 – Final Closure Plan.

3.4.1.3 Elevation of Deepest Excavation

30 TAC §330.63(d)(4)(C)

The deepest elevation of excavation will be approximately 4017 feet above mean sea level (msl) in the leachate collection sumps. The minimum waste placement elevation will be approximately 4024 above msl (minimum base elevation of 4022 plus two-feet for protective sand layer). The maximum elevation of final cover will be 4305 feet above msl. The maximum elevation for disposed waste will be 4301.7 feet above msl (for the alternative cover profile). All elevations listed are in City of El Paso vertical datum.

3.4.1.4 Estimated Waste Deposition Rate and Site Life

30 TAC §330.63(d)(4)(D)

The estimated rate of disposal was calculated assuming an annual population increase of 2% in growth, and assuming a disposal rate of 497,309 tons per year (in 2014 tonnage) until Clint Landfill closes in 2030. 3,000 tons per year are assumed from 2011 through 2013. After Clint Landfill closes, McCombs Landfill will receive all of the waste that would have previously been received at the Clint Landfill, therefore the disposal rate at McCombs will raise from 45% of the county waste allocation to 100%. The 1990 base population for central, northeastern and northwestern areas of El Paso (areas where solid waste is planned to go to the McCombs Landfill) was used for the growth rate estimation. The population for the above mentioned areas in 1990 was 322,842 people. Using the rate above, and an airspace utilization factor of 1200 lb/cy, the estimated life of the Landfill is to 2059.

The total remaining Landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including waste and daily, intermediate and final cover), which provides capacity through 2014, based on table 3.4H-1 in Appendix 3H - Site Life Projections. The total remaining Landfill volume available for waste disposal including the remainder of Sector A and all subsequent planned sectors (B through K) is 62,853,182 CY, which provides a site life until 2059. Calculations and assumptions for this waste volume and site life are included in Appendix 3H - Site Life Projections.

3.4.1.5 Landfill Cross-Sections

30 TAC §330.63(d)(4)(E)and(F)

Cross sections of the Landfill are located in Appendix 3F. These sections show the existing ground elevations; anticipated base elevation of excavation; bottom, side slope and vertical fill elevations; permitted fill elevations; existing groundwater monitoring wells; and the liner and cover system elevations. Top of waste elevation; perimeter or toe berm details; gas vents or wells; and groundwater elevations are included by reference to other portions of the permit document. The sections shown are representative of the entire site.

3.4.1.6 Liner Quality Control Plan

30 TAC §330.63(d)(4)(G)

A quality control plan for the base composite liner system in accordance with §330.339 is provided in Appendix 3J - Liner Quality Control Plan. The components of the current alternative liner system (Scenario 1) are listed from top to bottom in Table 3.4-1 and components of the proposed alternative liner system (Scenario 2) are listed from top to bottom in Table 3.4-2. It should be noted that the modeling results for both Scenario 1 and Scenario 2 are provided in Appendix 3J. The components for the expansion piggyback liner (Scenario 3) onto the existing unlined MSW area are listed from top to bottom in Table 3.4-3. The expansion piggyback liner will be placed in Sectors H, I, and J (approximately 64 acres, see Drawing P3-28B in Appendix 3G, Attachment 4). Detail drawings of the liner system are located in Appendix 3G - Construction Design Details, Drawing P3-28 – Landfill Base Plan

Table 3.4-1
Components of the Scenario 1 Liner System in Descending Order

Liner System Component	Description	Thickness
Protective Cover	Sand with coefficient of permeability greater than or equal to $1x10^{-3}$ cm/sec	24 inches
Geomembrane Liner	Textured HDPE Geomembrane (permeability less than or equal to $2x10^{-13}$ cm/sec)	60 mil
Compacted Soil Liner	Compacted Caliche with a coefficient of permeability less than or equal to $1x10^{-7}$ cm/sec	6 inches
Compacted Soil Liner	Compacted Native Soil or Interim Cover Soil	6 inches

Table 3.4-2
Components of the Scenario 2 Liner System in Descending Order

Liner System Component	Description	Thickness
Protective Cover	Sand with coefficient of permeability greater than or equal to $1x10^{-3}$ cm/sec	24 inches
Geomembrane Liner	Textured HDPE Geomembrane (permeability less than or equal to $2x10^{-13}$ cm/sec)	60 mil
Geosynthetic Clay Liner	Geosynthetic Clay Liner (GCL) with a coefficient of permeability less than or equal to $5x10^{-9}$ cm/sec	Approx. 0.24 inches
Compacted Soil Liner	Compacted Native Soil or Interim Cover Soil	6 inches

Table 3.4-3
Components of the Scenario 3 Liner System in Descending Order

Liner System Component	Description	Thickness
Protective Cover	Sand with coefficient of permeability greater than or equal to $1x10^{-3}$ cm/sec	24 inches
Geomembrane Liner	Textured HDPE Geomembrane (permeability less than or equal to $2x10^{-13}$ cm/sec)	60 mil
Geosynthetic Clay Liner	Geosynthetic Clay Liner (GCL) with a coefficient of permeability less than or equal to $5x10^{-9}$ cm/sec	Approx. 0.24 inches
Geogrid Stabilization Layer	Uniaxial Layers Placed Perpendicular to One Another	2 layers
Interim Cover Soil	Sand with coefficient of permeability greater than or equal to $1x10^{-3}$ cm/sec	6 inches
Compacted Buffer Soil	On Site Soil	36 inches

3.4.1.7 Final Cover Quality Control Plan

30 TAC §330.457

A quality control plan for the final cover system is included in Appendix 3O. Detail drawings of the final cover system are provided in Appendix 3G, Drawing P3-33 - Final Cover Plan, and Drawing P3-34 – Final Cover Details. The components of the prescriptive final cover system for lined areas of the Landfill are listed from top to bottom in Table 3.4-4 below. The components of the prescriptive final cover system for unlined areas of the Landfill are listed from top to bottom in Table 3.4-5. The components of the alternative final cover system (for both lined and unlined Landfill areas) are listed from top to bottom in Table 3.4-6.

Table 3.4-4
Components of the Prescriptive Final Cover System in Descending Order (Lined Landfill)

Cover System Component	Description	Thickness
Topsoil Layer	Native Topsoil or Rock Armoring	6 inches topsoil or 4 inches rock
Erosion Layer	Earthen Material	12 inches
Flexible Membrane Cover	Textured LLDPE or VLPE Liner	40 mil
Infiltration Layer	Sand with a permeability less than or equal to $1x10^{-5}$ cm/sec	18 inches
Intermediate/Daily Cover	Native Soil	12 inches

Table 3.4-5
Components of the Prescriptive Final Cover System in Descending Order (Unlined Landfill)

Cover System Component	Description	Thickness
Topsoil Layer	Native Topsoil or Rock Armoring	6 inches topsoil or 4 inches rock
Erosion Layer	Soil with a coefficient of permeability less than or equal to $1x10^{-5}$ cm/sec	18 inches
Intermediate/Daily Cover	Native Soil	12 inches

Table 3.4-6
Components of the Alternative Final Cover System in Descending Order

Cover System Component	Description	Thickness
Top Layer	Rock Armoring	4 inches
Erosion Layer	Material placed at 90% compaction	18 inches
Support Layer	Material placed at 80% compaction	6 inches
Intermediate/Daily Cover	Native Soil	12 inches

3.4.2 Storage and Transfer Units

3.4.2.1 Citizen's Collection Area

All residents and some commercial haulers will be directed to the PDA to dispose of wastes in roll-off containers. Trained Landfill personnel will be positioned at the public drop-off area and working face to visually screen for prohibited items. Customers disposing of bulky items and white goods will also be directed towards the PDA for unloading. Acceptable bulky items and white goods include automobiles, metal tanks, large metal pieces, and household appliances that have had all chlorinated fluorocarbons (CFCs) removed in accordance with 40 CFR §82.156(f). These items will be recycled by a permitted salvage company under contract with the City.

The geologic data submitted to the TCEQ as part of the 2002 MPA has been reviewed and approved by George Richardson, Professional Geologist in the State of Texas. The geologic data, including the boring logs and cross sections, are located in Appendix 3K – Geology.

An updated Site Characteristics and Monitoring Plan has been developed by Parkhill, Smith and Cooper to conform with the requirements of 30 TAC §330.63(e) (Appendix 3K, Attachment 1).

The information provided within the Geology Report and supporting documents in Appendix 3K generally conforms with the requirements of 30 TAC §330.63(e). This permit amendment includes a request for a vertical expansion of the Landfill but no lateral expansion of the Landfill footprint. Prior to starting work on this permit amendment and during the subsequent permit review and comment period, TCEQ stated, since there is no lateral expansion of the Landfill no additional geologic site characterization is necessary.

Section 3.6
GROUNDWATER SAMPLING AND ANALYSIS PLAN
30 TAC §330.63(f)

A Groundwater Sampling and Analysis Plan prepared by Parkhill, Smith and Cooper (PSC) in 2009 has been provided in Appendix 3L – Groundwater Sampling and Analysis. This plan was prepared in accordance with the standards set forth in 30 TAC §330.63(f).

3.7.1 Introduction

This landfill gas (LFG) management plan (Plan) has been developed as required by 30 TAC §330.63(g) for the Landfill located in El Paso, Texas. This LFG management plan is consistent with the requirements set forth in 30 TAC §330.371 and provides a site-specific approach for completing LFG management. This Plan describes the existing and potential future LFG management system and discusses the operation and monitoring of these systems, including verification of results, notification procedures, and possible remediation activities. Landfill Gas Management Plans developed by R.W. Beck, dated April 3, 2009, VIVA Environmental, Inc, dated November 27, 2001, and AGRA Earth and Environmental Group, dated April 8, 1994, were used in the development of the following section and are included for reference as Appendix 3M, Attachment 4.

3.7.1.1 Purpose

Compliance with §330.371(a) requires landfills to implement a routine LFG monitoring program to ensure that the following conditions are met:

- Concentrations of methane gas does not exceed 1.25% by volume in facility structures (excluding gas control or recovery system components); and
- Concentrations of methane gas does not exceed 5% by volume in monitoring points, probes, or other matrices at the facility boundary.

The purpose of this plan is to provide guidelines for the management of LFG and to provide guidance if the levels of methane exceed the limits specified above. Pursuant to §330.371(c), if methane levels are exceeded, the owner or operator shall take the following steps:

- Ensure protection of human health, and notify the Executive Director, local and county officials, emergency officials, and the public of the exceedance;
- Within seven days of the detection, operating records shall be updated to reflect the concentration of methane gas levels detected and the steps that were taken to protect human health; and
- Within 60 days of exceedance, a remediation plan shall be implemented to control methane gas releases. Copies of the remediation plan shall be placed in the operating record, provided to the Executive Director, and notification to the Executive Director that the plan has been implemented. The remediation plan shall include the nature and extent of the problem and the proposed remedy. After review, the Executive Director may require additional remediation measures.

3.7.1.2 General

In accordance with §330.371(d), the Executive Director may establish alternative schedules for demonstrating compliance with subsections §330.371(b) and §330.371(c).

In accordance with §330.371(e), the LFG monitoring and control program will continue for a period of 30 years after certification of final closure of the facility or until the owner or operator receives written authorization to reduce the program. Authorization to reduce LFG monitoring and control shall be based on demonstration that there is not potential for gas migration beyond the property boundary or into site structures. Demonstration shall be supported by collected data and additional studies, as required.

In accordance with §330.371(f), the LFG monitoring and control system shall be revised as needed to maintain current and effective LFG monitoring and control. Post-closure shall not interfere with the function of the LFG monitoring and control systems. Any underground utility trenches that cross the facility boundary shall be vented and monitored regularly.

3.7.2 Site Characteristics

In accordance with §330.371(b), the Landfill shall implement a routine LFG monitoring program to ensure the standards of §330.371(a) are met. The type and frequency of monitoring shall be based on the existing site conditions. The minimum frequency of monitoring shall be quarterly.

3.7.2.1 Soil Conditions

The site geologic conditions present at the Landfill are discussed in Appendix 3K - Geology.

3.7.2.2 Hydrogeologic Conditions

The hydrogeologic conditions present at the Landfill are discussed in Appendix 3K – Geology.

3.7.2.3 Hydraulic Conditions

Hydraulic conditions at the Landfill are discussed in Section 3.3 – Facility Surface Water Drainage Report.

3.7.2.4 Facility Structures within the Property Boundary

The Landfill has a permit boundary of approximately 347-acres. The existing structures located within the property boundary include the existing gatehouse (fee collection building), the maintenance building and a small storage building. The scale house building shall be monitored quarterly with a hand held gas meter at the base of each exterior wall and ambient air. As part of the facility expansion, it is anticipated

that a new equipment maintenance building and scale house will be constructed to the south of the existing buildings within the property boundary (Drawing P3-17 in Appendix 3E). Any new Landfill structures will be monitored similarly to the existing structures.

3.7.2.5 Underground Utilities

Underground utility lines that exist within the future disposal footprint of the landfill will be removed prior to the landfill expansion. No utility lines exist within the current disposal footprint of the landfill. Overhead lines provide electricity and telephone service to the buildings on-site. Consequently, monitoring or reporting of easement for buried utilities is not applicable.

3.7.2.6 Offsite Structures

In accordance with §330.371(h), since off-site habitable structures are located within 3,000 feet of the waste placement boundary, a permanent perimeter monitoring system is installed at the Landfill and is discussed in more detail below.

3.7.3 Existing Monitoring System

The existing LFG systems consists of gas monitoring probes (GMP) located along the perimeter of the landfill property as well as a landfill gas migration control system (GMCS) located along the western perimeter of the Landfill. The existing systems are shown on Drawing P3-43 in Appendix 3M and are described in further detail below.

3.7.3.1 Gas Monitoring Probes

GMP-1 through GMP-8 were installed in 1994. Description of the installation practices and sample boring and well installation logs are provide in the Landfill Gas Management Plan prepared by AGRA Earth & Environmental Group (AGRA) on April 8, 1994.

GMP-9 through GMP-17 were installed in 2001 by VIVA Environmental, Inc. (VIVA). Description of the installation practices, boring logs and well installation logs are provide in the Landfill Gas Management Plan prepared by VIVA on November 27, 2001.

In 2003, GMP-3 was replaced with GMP-3A and GMP-3 was decommissioned, plugged and abandoned. GMP-3A was installed adjacent to GMP-3 at a depth of approximately 67 feet below ground surface (bgs). The City also decommissioned, plugged and abandoned GMP-4, GMP-5, and GMP-6 based on previous TCEQ approval due to the GMPs no longer falling on the outside perimeter of the landfill. The GMPs were abandoned in November 2003.

In 2004, GMP-18 and GMP-19 were installed to eventually replace GMP-2 and GMP-3A, respectively. The current locations of GMP-2 and GMP-3A are too close to the waste limits, and the locations of GMP-18 and GMP-19 are more suitable for gas monitoring at these two locations. GMP-2 and GMP-3A readings have returned to

compliance due to the installation and operation of the active GMCS along a portion of the western perimeter as part of the gas migration remediation plan, but the GMPs have yet to be decommissioned, plugged and abandoned.

Temporary gas monitoring probes GMP-20, GMP-21, and GMP-22 were installed in 2006 to provide additional information on gas migration. Readings taken from the temporary probes have demonstrated that the gas migration issue has been mitigated. These probes are to be decommissioned, plugged and abandoned at a future date.

Boring and well installation logs for GMP-18 through GMP-22 are provided in the Landfill Gas Management Plan prepared by R.W. Beck in 2009.

The permanent Site Methane Monitoring Network currently consists of fourteen (14) GMPs (GMP-1 and GMP-7 through GMP-19) spaced approximately 1,000 feet apart. The GMPs were installed along the permitted area and property boundary. A review of on-site geological/soil data revealed little evidence of any laterally extensive stratographic units which could significantly influence migration of any gases produced within the landfill cells (AGRA, 1994). Additionally, geomembrane liner systems that will exist in future landfill cells should minimize potential for LFG migration away from the landfill footprint.

3.7.3.2 Passive Gas Vents

In June 2000, two passive venting wells (PV-1 and PV-2) were installed in order to intercept and vent methane gas prior to reaching GMP-2 and GMP-3. Both venting wells were installed to a depth of approximately 60-feet bgs in order to capture methane gas at depths where the majority of the elevated methane gas levels were detected and may be generated. In 2001, one vertical passive venting well (PV-3) was installed to a depth of 55-feet below grade.

In November of 2003, PV-1A and PV-2A were constructed to help mitigate the high methane readings recorded in GMP-2 and GMP-3. PV-1, PV-1A and PV-2A still exist within in the LFG management system; however, these wells were capped during the installation of the GMCS.

Five additional passive gas vents were installed in 2006 to provide additional gas venting in the area between GMP-2 and GMP-3. PV-3R was a replacement vent of PV-3 installed in 2001. PV-3 was abandoned in November 2003 as it falls within the landfill footprint and was no longer required to reduce methane levels measured at GMP-4.

PV-2 through PV-7 were converted into active gas extraction wells as part of the GMCS construction. The GMCS system is described in more detail in Section 3.7.3.3 below.

It should be noted that existing PVs (capped and active) will likely be decommissioned, plugged and abandoned prior to the vertical expansion on top of the existing landfill, assuming that this section of the existing landfill is no longer producing significant amounts of LFG at that time. However, in the event that the PVs still contain a significant amount of LFG, the PVs will be piped horizontally to

the landfill perimeter for LFG venting/collection. PVs will not be extended vertically through the future expansion landfill geomembrane liner.

The locations of all active and abandoned GMPs and PVs are shown on Drawing P3-42 in Appendix 3M. Table 3.7-1 provides the approximate coordinates, elevations, and installed depths below ground surface at the time of installation of the GMPs and PVs of the existing system.

Table 3.7-1
Existing LFG Monitoring System Monitoring Points

Reference Point	Date Installed	Northing[1]	Easting[1]	Depth Below Ground Surface	Ground Elevation
GMP-1	1994	10738395.3	413850.0	55-feet	4086.41[2]
GMP-2	1994	10739603.6	413889.0	55-feet	4088.11[2]
GMP-3	1994		Abandoned		
GMP-3A	2003	10740576.6	413938.6	55-feet	4096.68[2]
GMP-4	1994		Abandoned		
GMP-5	1994		Abandoned		
GMP-6	1994		Abandoned		
GMP-7	1994	10738660.9	415896.4	10-feet	4072.61[2]
GMP-8	1994	10738332.2	414822.2	55-feet	4072.38[2]
GMP-9	2001	10738234.7	416875.7	55-feet	4078.55[2]
GMP-10	2001	10739228.3	417042.1	55-feet	4084.32[2]
GMP-11	2001	10740226.8	417080.2	55-feet	4087.33[2]
GMP-12	2001	10741225.2	417116.3	55-feet	4082.85[2]
GMP-13	2001	10742226.1	417153.5	55-feet	4082.21[2]
GMP-14	2001	10742561.4	416214.0	55-feet	4075.69[2]
GMP-15	2001	10742613.3	415216.7	55-feet	4067.69[2]
GMP-16	2001	10742664.4	414138.6	55-feet	4048.13[2]
GMP-17	2001	10741690.8	413989.8	55-feet	4056.37[2]
GMP-18	2004	10739597.9	413835.6	65-feet	4086.00[1]
GMP-19	2004	10740582.1	413863.0	65-feet	4085.39[1]
GMP-20	2006	10740260.4	413927.8	65-feet	4098.00[1]
GMP-21	2006	10739947.8	413908.1	65-feet	4094.53[1]
GMP-22	2006	10740120.7	413858.4	65-feet	4085.69[1]
PV-1	2000	10739588.0	413938.6	60-feet	4092.70[2]
PV-1A	2003	10739578.0	413938.6	55-feet	4090.00[1]
PV-2	2000	10740520.5	413971.0	60-feet	4101.28[2]
PV-2A	2003	10740550.5	413971.0	55-feet	4093.11[1]
PV-3	2001		Abandoned		
PV-3R	2006	10740452.5	414057.0	60-feet	4081.81[2]
PV-4	2006	10740279.1	414045.0	60-feet	4102.00[1]
PV-5	2006	10740094.4	414034.1	60-feet	4101.72[1]
PV-6	2006	10739890.3	414088.3	60-feet	4101.50[1]
PV-7	2006	10739641.6	414044.0	60-feet	4090.41[1]

[1] Northing and Easting locations and ground elevations provided are approximate and based on existing conditions locations and 2011 surveyed contours.
[2] Elevations obtained from VIVA, 2001.

3.7.3.3 Gas Migration Control System (Western Perimeter)

Existing gas monitoring probes (GMP-2, GMP-3, GMP-20, and GMP-21) located along the western perimeter of the Landfill have had periodic elevated methane readings above the regulatory limit of 5%. The Landfill was placed under enforcement action by the TCEQ to mitigate the affected GMPs due to the elevated methane readings.

In an attempt to reduce the methane readings, PV-1A and PV-2A were installed in 2003 and PV-3R through PV-7 were installed in 2006 along the western waste limit of the Landfill; however, the passive vents installed were not effective in controlling gas migration toward the affected GMPs. As a result, the City decided to install an active gas migration control system (GMCS) as part of the site gas remediation plan.

The GMCS is an active extraction system to control LFG migration in the affected area. The system is a partial active system, because it was installed only along a distance of approximately 1,000 feet over the northwestern portion of the unlined landfill. Existing PV-2 through PV-7 were converted into active gas extraction wells as part of the GMCS. In addition to the 6 converted extraction wells, the GMCS consists of LFG header and lateral pipes, a condensate sump and pump system, a blower/flare station, a condensate storage tank, and an air compressor system to power the condensate pump system. Since the GMCS system installation and subsequent start up in August of 2009, the GMP readings have been in compliance. If there are methane readings out of compliance in the future, further investigation will be conducted to ensure that the existing system is performing optimally. In the case that the system is running at peak performance and methane readings are still out of compliance, additional PVs may be added to the GMCS network. GMCS details are provided in the R.W. Beck Landfill Gas Management Plan of 2009.

3.7.4 Potential Future LFG Management System

3.7.4.1 NSPS Requirements

Pursuant to 40 CFR Part 60, Subpart Cc §60.33c, "a State plan shall include control of MSW landfill emissions at each MSW landfill meeting the following three conditions:

1. The landfill has accepted waste at any time since November 8, 1987, or has additional design capacity available for future waste deposition;
2. The landfill has a design capacity greater than or equal to 2.5 million megagrams and 2.5 million cubic meters. The landfill may calculate design capacity in either megagrams or cubic meters for comparison with the exemption values. Any density conversions shall be documented and submitted with the design capacity report; and,
3. The landfill has a nonmethane organic compound emission rate of 50 megagrams per year or more."

Design Capacity

One threshold for NSPS requirements is the Landfill having a design capacity of 2.5 million megagrams (Mg) or cubic meters. The Landfill design capacity is over the NSPS threshold of 2.5 million Mg.

NMOCs

Because the Landfill is over the design capacity threshold, nonmethane organic compound (NMOC) monitoring is required at a Tier II level. The last NMOC monitoring event conducted at the Landfill was completed in March 2007. The results from the NMOC monitoring indicate that the maximum NMOC concentration will occur in year 2047 at a concentration of 34.69 Mg (under the 50 Mg threshold). According to the 2007 test results, the Landfill is currently under the annual air emissions threshold of the Federal New Source Performance Standards (NSPS), and as a result, there is no present requirement for the City to install a LFG collection and control system (GCCS) covering the entire landfill. The latest NMOC results are provided in Appendix 3M.

NMOC monitoring will continue, as necessary, in accordance with the site air permit and the Landfill will continue to evaluate the need for an active GCCS based on future NMOC monitoring results.

3.7.4.2 Active Gas Collection and Control System

Although the Landfill is currently not required to install an active GCCS system, the following system has been designed with the assumption that the Landfill will either eventually have to comply with NSPS standards, or will choose to install an active GCCS voluntarily to further landfill gas to energy efforts.

The designed active GCCS will consist of a series of wells and piping used to convey LFG to an open flare station for combustion or to a landfill-gas-to-energy conversion system. The GCCS will be constructed in a similar manner to the GMCS and may include some of the same components as the GMCS. GCCS components will include:

- Header/Manifold
- Lateral
- Vertical Gas Wells (GW)
- Cleanout Stations
- Condensate Sumps
- Flare Station

As shown on Drawing P3-39 in Appendix 3M, the GWs were designed at a radius of influence (ROI) of 150-feet. The ROI was developed based on previous experience with similar type soils (silty sand/sandy) and drier waste moisture content. The actual location of the GWs may vary dependent on site conditions at the time of installation.

3.7.4.3 Existing System Modifications

Upon Landfill expansion, it is anticipated that GMP-7 will be removed from the monitoring system and that GMP-23 will replace GMP-7 in the monitoring network (Drawing P3-43 in Appendix 3M). GMP-23 will be located on the outside of the Landfill limits, but inside the property boundary. GMP-7 will be decommissioned, plugged and abandoned upon installation of GMP-23. GMP-23 will be installed following the guidelines set forth in Section 4.2 of the AGRA Landfill Gas Monitoring Plan, 1994 (Appendix 3M, Attachment 4).

3.7.5 Monitoring Plan

3.7.5.1 Perimeter Monitoring

Perimeter Monitoring Network

The LFG monitoring probe network at the Landfill includes a total of fourteen existing LFG monitoring probes (GMP-1 and GMP-7 through GMP-19) located along the perimeter of the waste fill area. Locations of the existing GMPs are shown on Drawing P3-43 in Appendix 3M. As mentioned previously, GMP-7 will be replaced with GMP-23 in the permanent monitoring network.

Landfill Gas Monitoring Probes

LFG monitoring probes have been installed along the perimeter of the waste fill area. Boring logs and typical construction details for the GMPs have been provided in previous versions of the LFG Management Plan (R.W. Beck 2009, VIVA 2001, AGRA 1994) which are provided in Appendix 3M, Attachment 4. Future LFG monitoring probes will be installed in accordance with the detail shown on Drawing P3-44 in Appendix 3M.

Monitoring Procedures

During each monitoring event, the GMPs will be monitored for the following parameters:

- Probe gas pressure at each probe;
- Methane gas concentrations at each probe;
- Barometric pressure during the monitoring event; and
- Ambient temperature during the monitoring event.

Monitoring for gas composition and pressure will be performed using a portable combustible gas indicator capable of measuring the above parameters. Prior to the start of monitoring, the tester shall calibrate monitoring instruments in accordance with the manufacturer's specifications. The instrument is factory calibrated semi-annually. The tester should also record time, temperature, barometric pressure, and weather conditions prior to the start of the monitoring period. Each GMP shall be monitored using the following monitoring procedures:

- Check GMP's integrity;
- Determine pressure within sealed monitoring tube;
- Determine methane concentrations at each location; and
- Record all data on the LFG Monitoring Report Form (Appendix 3M).

Maintenance Procedures

Each time LFG monitoring is conducted, the sampler will inspect the integrity of the LFG monitoring probes. The sampler will record pertinent information on the LFG Monitoring Report Form provided in Appendix 3M. The LFG Monitoring Report Form will be kept in the Site Operating Record. The sampler will perform the following at each monitoring event:

- Verify that the GMP identification number is clearly labeled on the outer casing or lid;
- Verify that the protective casing is intact and is not bent or excessively corroded;
- Verify that the protective barrier pipes are intact;
- Verify that the working pad is intact;
- Verify that the lock is functional;
- Verify that the hinged cover is in working order; and
- Verify that the inner casing is intact.

If damage or excessive wear to the LFG monitoring probe is observed, it will be reported to the landfill manager and repaired within 30 days of the date damage is observed. If it is not possible to repair the GMP, the LFG monitoring probe will be decommissioned and replaced within 60 days from the TCEQ approval date of the permit modification requesting replacement of the GMP. Upon completion of the replacement GMP, an as-built documentation report including boring and well installation logs will be submitted to the TCEQ.

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.2 GMCS/GCCS Monitoring

GMCS Monitoring Network

The gas migration control system network currently consists of 6 active gas wells that were converted from passive gas vents (PV-2 to PV-7). The system was installed to mitigate methane exceedance detected in GMP-2, GMP-3, GMP-20 and GMP-21 along the western perimeter of the unlined landfill area. In the event that the levels of methane increase above regulatory standards in the affected GMPs, expansion of the existing GMCS may occur. It is anticipated that this system will eventually be replaced by the GCCS network.

GCCS Monitoring Network

The GCCS is anticipated to be installed either upon the landfill reaching NSPS standards requirements or on a voluntary basis. This is dependent both on the current permitted waste capacity (which the landfill is currently exceeding the limits of 2.5 million megagrams or 2.5 million cubic meters) and the current NMOC concentration within the LFG. As described in Section 3.7.4.1, the actual timing for the Landfill reaching NSPS standards is currently unknown and will be dependent on future NMOC monitoring.

Monitoring Procedures

The GMCS and GCCS are designed to collect LFG and prevent fugitive emissions from the Landfill. Since the rate of LFG production within the landfill varies, the amount of gas withdrawn by the GMCS/GCCS GWs should also be adjusted. During each monitoring event, the Flare (and/or potential gas-to-energy conversion system) will be monitored and the GWs will likely be monitored for the following parameters:

- Gas flow at each location;
- Gas pressure at each location;
- Gas temperature at each location;
- Methane gas concentrations at each location;
- Oxygen gas concentrations at each location;
- Barometric pressure during the monitoring event; and
- Ambient temperature during the monitoring event.

Monitoring for gas composition, pressure, and temperature will be performed using a portable combustible gas indicator capable of measuring the above parameters. Prior to the start of monitoring, the tester shall calibrate monitoring instruments in accordance with the manufacturer's specifications. The GMCS/GCCS will likely be sampled using the following sampling procedure:

- Record date, time and current weather conditions;
- Record initial data from Flare skid;
- Perform GW maintenance check at each GW;
- Record above parameters at each GW;
- Adjust flow through the wellhead at each GW based on the methane and oxygen measurements (if necessary); and
- Record end data from Flare skid.

Maintenance Procedures

When the GCMS/GCCS monitoring includes the monitoring of the GWs, the sampler will inspect the integrity of the GWs. The sampler will record pertinent information on the LFG Monitoring Report Form which will be placed in the Site Operating Record. The sampler will also observe the wellhead during the monitoring event to

ensure no damage has occurred to the wellhead. If damage or excessive wear to the GW or wellhead is observed, it will be reported to the landfill manager and repaired within 30 days of the date damage is observed. If it is not possible to repair the GW, the Landfill will evaluate the effectiveness of replacing the GW within the gas collection system. If the GW is replaced, an as-built documentation report will be submitted to the TCEQ including boring and well installation logs.

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.3 Facility Structures Monitoring

Monitoring Procedures

On-site buildings and structures designed for human occupation will be monitored, at a minimum, quarterly with a portable combustible gas indicator. The buildings shall be monitored quarterly with a hand held gas meter at the base of each exterior wall and also the ambient air.

If methane concentration exceeded allowable limits within structures, the building will be immediate evacuated and ventilated by opening doors and windows and placing a portable blower to blow clean air into the building. Notification consistent with the procedures outlined in Section 3.7.6.2 will be implemented immediately.

Maintenance Procedures

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.4 Recordkeeping/Reporting

Field monitoring data records will be placed in the Site Operating Record and maintained onsite for inspection. Field data will be recorded on the LFG Monitoring Report Form provided in Appendix 3M.

3.7.5.5 Monitoring Frequency

LFG monitoring probes and facility structures will be monitored quarterly at a minimum. The facility will monitor the locations more frequently if monitoring results indicate that LFG migration is occurring or is accumulating in the structures.

GMCS monitoring is required on a monthly basis; however, Landfill personnel typically monitor on a weekly basis. GCCS monitoring will occur similarly to the GMCS monitoring and shall comply with 40 CFR Part 60, Subpart WWW §60.756.

3.7.6 Action Plan

3.7.6.1 Initial Response Measures

This action plan has been prepared for the protection of human health in the event concentrations of methane exceed allowable limits as required under 30 TAC §330.371. The action plan will address methane level exceedance measurements for both buildings and perimeter monitoring probes.

Emergency Action

As defined in Section 3.7.1.1, the first action in the event that methane is detected at levels above regulatory limits is to protect human health. The following actions will be taken to protect human health dependent on the exceedance location.

Permit Boundary

If methane levels are detected above the regulatory limit in one of the GMPs, the landfill manager will be notified. The immediate emergency response measure will be for the landfill manager to determine if any nearby buildings or structures (including offsite) are at risk and if evacuation of the buildings or structures should be requested.

Structures

If methane concentration exceeded allowable limits within structures, the building will be immediate evacuated and ventilated by opening doors and windows and placing a portable blower to blow clean air into the building. The landfill manager will be notified of the exceedance, and personnel will not be allowed to reenter the building until additional measurements are taken.

Verification Procedures

Once emergency action measures have been taken to protect human health, the landfill manager will require monitoring personnel to begin verification procedures. Verification procedures are intended to determine if the methane levels detected are accurate, or if erroneous levels have been detected.

Permit Boundary

Verification of the detected methane levels above regulatory limits in the GMPs will be conducted within 24 hours using the following procedures:

- Recalibrate gas detection equipment according to manufacturer's recommendations;
- After recalibration of the gas detection equipment, recheck the methane concentration in the GMP; and
- Recheck the methane concentration again within 7 days of the initial reading.

If the measured concentrations of methane are not above regulatory limits in the verification procedure, routine monitoring procedures will resume.

If the follow-up readings suggest that there are methane gas levels exceeding the regulatory limits, notification and remediate procedures must be implemented as described in Section 3.7.6.2 and Section 3.7.7.

Structures

Verification of detected methane levels in the facility structures shall be conducted within 24 hours of the exceedance by monitoring methane levels throughout the structure using a portable gas meter. Readings will be taken in each room and in any confined spaces. If any natural gas appliances exist in the structure, they should be checked for leaks.

If concentrations of methane above the regulatory limit are not detected, personnel may return to the structure. Daily follow-up verification readings must be made for a period of one week after the exceedance measurement. If the follow-up readings suggest that there are methane gas levels exceeding the regulatory limits, notification and remediate procedures must be implemented as described in Section 3.7.6.2 and Section 3.7.7.

3.7.6.2 Notification Procedures

When methane concentrations are detected above the regulatory limit, notification will be made immediately in accordance with §330.371. Within seven days from the date of an initial reading above allowable limits, the owner shall place in the Site Operating Record:

- Concentration of methane gas levels detected as well as time, date, and location;
- Description of steps taken to protect human health; and
- Information regarding the notifications to the Executive Director, local and county officials, emergency officials, and the public of the exceedance;

Within 60 days, the City shall take the following actions:

- Submit and implement a remediation plan for the methane gas releases that describes the nature and extent of gas migration and proposed remedy to the Executive Director; and
- Provide notification to the Executive Director that the remediation plan has been implemented.
- Place a copy of the remediation plan in the Site Operating Record.

3.7.7 Remediation Plan

If verification procedures confirm that the methane levels detected are above the regulatory limits in either an onsite structure or GMP, remediation actions shall be implemented within 60 days of detection. The initial remediation action will be an investigation of the cause of the exceeding methane levels. The investigation will be completed using all or part of the following items:

- Additional gas sampling at the landfill to determine concentrations of methane;

- Soil gas sampling to determine the extent of gas migration beyond the permitted landfill facility;
- Additional or increased GMP monitoring in the area of exceedance;
- Installation of additional GMPs or PVs in the area of exceedance; and
- Installation/expansion of an active LFG collection and control system.

Based on the results of the investigation, the Landfill will determine the appropriate course of action to ensure future methane concentration levels are below regulatory standards. In accordance with 30 TAC §330.371, a remediation plan describing the nature and extent of the problem and the proposed remedy will be submitted to the Executive Director within 60 days of detection that notifies the Executive Director of the plan and that the plan has been implemented. Copies of the remediation plan will be kept in the Site Operation Record. If the remediation plan includes any changes to the LFG Management Plan, approval will be received from the TCEQ prior to implementation.

3.7.8 Backup Plan

This backup plan will be applicable under the assumption that the active GCCS is required to be installed under NSPS and has been developed in accordance with 30 TAC §330.371(g)(3). In the event that the GMCS/GCCS breaks down, the backup plan will be to repair the GMCS/GCCS as soon as possible, dependent on weather, contractor, material, and equipment availability. During the repair period, monitoring frequency on the site GMPs will increase to monitoring levels determined at the time of repair.

The Final Closure Plan has been prepared in compliance with applicable regulations (30 TAC §330.63(h), 330.457, and 330.459) for the McCombs Landfill. Within 180 days of the last receipt of wastes for any MSWLF unit, the owner or operator will complete the installation of a final cover system as permitted, designed and constructed to minimize infiltration and erosion. This final closure plan includes the following:

- A description of the prescriptive final cover design, including methods for installation;
- A description of the alternative final cover design, including justification in accordance with the *Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill,* and methods for installation;
- An estimate of the largest area requiring final cover at any time during the active life of the landfill;
- An estimate of the maximum inventory of wastes on-site over the active life of the landfill; and
- A schedule for completing all final cover activities.

A copy of this closure plan will be included in the site operating record.

The Final Contour Map for the Landfill depicting the final contours, site access roads, top and side slopes, and surface drainage features is located in Appendix 3E - Site Layout Plans.

The estimated cost to hire a third party to perform the closure project can be found in Appendix 3N, Attachment 2 - Closure Cost Estimates.

3.8.1 Description of Final Cover Design

30 TAC §330.457(e)(1)

The final cover will be applied to areas of the Landfill as they reach final contour elevations shown on the Final Cover Plan in Appendix 3G - Construction Design Details, Drawing P3-33. The prescriptive final cover for areas of the Landfill with a synthetic bottom liner consists of a minimum of an eighteen inch infiltration layer over the intermediate and daily cover layers having a coefficient of permeability less than or equal to $1x10^{-5}$ cm/sec. The infiltration layer is then overlain with a synthetic flexible membrane with permeability less than that of the bottom liner system. Twelve inches of earthen material are then placed, providing the erosion layer. On top of the erosion layer, six inches of vegetative layer (or 4 inches of rock layer) is placed that can support and sustain native plan growth. The rock layer, if used instead of the

vegetative layer, would consist of rounded to sub-rounded river rock, crushed angular to sub-angular rock, or a combination of the two.

The synthetic membrane shall be a minimum of 40 mils (LLDPE) to ensure proper seaming. Drawing P3-34 in Appendix 3G - Construction Design Details, shows details for the prescriptive final cover system design for areas of the landfill that have a synthetic bottom liner. Drawing P3-29 in Appendix 3G details the Typical Landfill Perimeter Section, which shows how the liner is anchored to the existing grades.

An alternative final cover system has been designed for the McCombs Landfill. The alternative cover system includes only soil cover as opposed to a synthetic liner. The system will include the 12 inches of preliminary cover (6 inches of daily cover and 6 inches of intermediate cover) as is in the prescriptive cover, a 6-inch support layer, an 18 inch erosion layer, and a 4-inch top layer consisting of rock armor. The alternative final cover is in lieu of the low permeability soil, synthetic membrane liner and topsoil (or rock) described in the prescriptive cover above. Drawing P3-35 in Appendix 3G provides detail on the alternative final cover profile.

Appendix 3N - Closure Details presents a demonstration of the infiltration equivalency of the two final cover system options and justification for the alternative earth cover in accordance with the "*Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill"*.

Appendix 3B, Attachment 5 presents the calculated soil loss for the two final cover system options.

The prescriptive cover sequencing will be different for areas with bottom liner than for those without and both are described below.

3.8.1.2 Sequence of the Final Cover Installation

The following provides a general sequencing plan for the prescriptive final cover system installation for the Landfill areas that include a synthetic bottom liner:

- Apply the final six inches of daily cover, and if not closed within 180 days apply six inches of intermediate cover;
- Place 18 inches of earthen material (with a coefficient of permeability less than or equal to 1 X 10^{-5} cm/sec) that will serve as the infiltration layer;
- Place 40 mil LLDPE geomembrane;
- Place 12 inches of earthen material that will serve as the erosion layer;
- Place the 6 inch minimum earthen vegetative layer that is capable of supporting and sustaining native plant growth (or place 4 inches of crushed rock or river rock armoring in lieu of 6 inch earthen vegetative layer); and
- Refer to Drawing P3-34 - Final Cover Details, in Appendix 3G for details of this final cover system design.

The following provides a general sequencing plan for the prescriptive final cover system installation for the McCombs Landfill areas that do not include a synthetic bottom liner:

- Apply the final six inches of daily cover, and if not closed within 180 days apply six inches of intermediate cover;
- Place 18 inches of earthen material (with a coefficient of permeability less than or equal to 1 X 10^{-5} cm/sec) that will serve as the infiltration layer;
- Place the 6 inch minimum earthen vegetative layer that is capable of supporting and sustaining native plant growth (or place 4 inches of crushed rock or river rock armoring in lieu of 6 inch earthen vegetative layer);
- Refer to Drawing P3-34 in Appendix 3G for details of this final cover system design.

It should be noted that the only area that may receive the prescriptive final cover for areas that do not include a synthetic bottom liner include areas of existing unlined Landfill that will not receive any further waste, the western outside slope of Sector I and the southern outside slope of Sector J. The areas of the slopes for Sectors I and Sectors J are identified on Drawing P3-33B in Appendix 3G, Attachment 4. All other areas will either receive the prescriptive final cover system (with bottom liner) or the alternative final cover system described below.

The following provides a general sequencing plan for the alternative final cover system installation for the McCombs Landfill areas (both with and without a synthetic bottom liner:

- Apply the final six inches of daily cover and 6 inches of intermediate cover;
- Apply 6 inches of support soil compacted to 80%;
- Apply 18 inches of erosion soil compacted to 90%;
- Apply 4 inches of top layer consisting of rock armor;
- Refer to Drawing P3-35 - Alternative Cover Details, in Appendix 3G for details of this final cover system design.

3.8.1.3 Site Preparation

Site preparation includes clearing and grubbing vegetation in areas to receive intermediate cover. The intermediate cover will be prepared and graded to meet the criteria set forth in the Final Cover Quality Control Plan. Additional clean fill material from on-site native soil can be used to meet the required contour elevations.

3.8.1.4 Prescriptive Final Cover Construction

Testing and Evaluation of the prescriptive final cover system will be completed in accordance with 30 TAC §330.457(c). For the prescriptive cover, the infiltration material will be placed in accordance with the Final Cover Quality Control Plan (located in Appendix 3P) and will be tested at least once per surface acre for coefficient of permeability. Permeability data will be submitted to the TCEQ executive director. A liquid limit (LL) of not less than 30 and a plasticity index (PI) of not less than 15 are required, but lower values of Atterburg limits may be acceptable.

The remaining layers (membrane, erosion and vegetative or rock layers) will be installed in accordance with the Final Cover Quality Control Plan. If rock is chosen as the final layer, it will be graded to provide an interlocking framework for slope stability and to minimize erosion for surface water.

3.8.1.5 Alternative Final Cover Construction

Testing and Evaluation of the alternative final cover system will be completed in accordance with the TCEQ Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill and findings of the Unsat-H model and report found in Appendix 3N - Closure Details. For the alternative cover, the support layer will be much less dense than the infiltration material utilized in the prescriptive cover. The Interstate Technology and Regulatory Council (ITRC) Alternative Landfill Technologies Team states that a range of 75-85% compaction is best for evapotranspiration monolithic soil final cover systems. This layer will be placed at 80% compaction.

The erosion layer will be installed in accordance to the TCEQ Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill and finding of the Unsat-H model and report found in Appendix 3N. This layer will be placed at 90% compaction.

3.8.1.6 Final Cover Construction Activities for both Prescriptive and Alternative Systems

A gas venting system will be implemented to dissipate the gas produced by anaerobic degradation of the waste at the site. Drawings P3-41 and P3-42, in Appendix 3M - Landfill Gas Management Details, provide landfill gas venting system details. Any gas collection system used at the site will be designed and installed with approval of the TCEQ.

Erosion and soil loss preventative measures and maintenance will be required for the final cover. Calculations using the Revised Universal Soil Loss Equation (RUSLE) for estimating soil loss on the final cover of the landfill can be seen in Appendix 3B, Attachment 5 – Closure Soil Loss Calculations. Refer to Appendix 3G for slope stability analysis.

3.8.2 Largest Area Requiring Final Cover

30 TAC §330.457(e)(2)

The largest open area at the McCombs Landfill at any given time is not expected to exceed approximately 222.8 acres for areas that will ever require final cover. The landfill development plan has been broken into different sections to be constructed over time and therefore smaller sections of the total may be closed individually or collectively as they reach permitted maximum elevations. The largest area of closure is during Sector G development, prior to the closure of Sector F, for which the total open area is 113.2 acres and the incremental closure area is 18.3 acres. Also included

at that time will be 70.8 acres in the existing unlined landfill area and 20.5 acres lined landfill area in the existing Phase I and II areas. The filling sequence is provided in the Appendix 3E - Site Layout Plans.

P3-45 provides the largest open area at any time during site development that will require final cover (222.8-acres). The final cover portrayed is for both the existing and future sector boundary extensions. P3-45 is only applicable at the time of Sector G development (i.e., prior to the development of the piggyback area). It should be noted final cover will not be placed on the existing unlined (70.8 acres) and lined (20.5 acres) areas prior to the piggyback liner unless the Landfill is closed prior to development of the piggyback area (Sectors H-J) and the vertical expansion of Sector K.

3.8.3 Maximum Waste Inventory

30 TAC §330.457(e)(3)

Approximately 5,964,060 cubic yards (cy) of waste (and intermediate cover) have been landfilled in the existing completed phases of the Landfill, as of December 31, 2010.

The total Landfill volume was estimated using AutoCAD by comparing the top of geomembrane to the top of final cover. The total remaining Landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including waste and daily**,** intermediate, and final cover), which provides capacity through 2014 based on table 3H-1 in Appendix 3H-Site Life Projections. The total remaining Landfill volume available for waste disposal including the remainder of Sector A and all subsequent planned sectors (B through K) is 62,853,182 CY. Given the remaining capacity above, the remaining estimated life of the Landfill is until 2059. The total volume in place at that time will be 68,817,242 CY.

3.8.4 Closure Schedule

30 TAC §330.457(e)(4), 330.457(f), and 330.457(g)

The McCombs Landfill will be efficiently closed by the following procedure:

- The Owner/Operator will provide written notification to the TCEQ within 45 days prior to beginning final closure activities stating their intent to close a section of the facility or the entire facility site. This notice will also be placed in the operating record.
- The Owner/Operator will publish a public notice of final closure in the largest circulating newspaper in the facility area within 90 days prior to beginning final closure activities of the entire facility site. This notice will include name, address, location of the facility, permit number, and date of final receipt of waste. Copies of the final closure plan will be made available for the public to review.

- At least one sign will be posted at the main entrance (and others where appropriate around the site perimeter) following the closure date notifying readers of the final date of closure.
- Barriers shall be installed at all entrances, gates, or access points to the Landfill following closure in order to prevent unauthorized dumping of solid waste.
- Final closure for the entire facility site shall begin no later than 30 days after the date on which the Landfill receives final waste. If the Landfill has remaining capacity and will likely continue to receive additional waste then final closure will continue no later than one year after receipt of final waste. If time beyond the one year is necessary, a request for extension may be submitted to the executive director for review and approval. The request must include documentation demonstrating the site had capacity to receive additional waste and that the owner/operator has taken steps and will continue to take steps to prevent threats to human health and environment from the unclosed portions of the site.
- The Final closure in accordance with this plan shall be completed within 180 of initiation of final closure activities. If it is likely to take beyond 180 days, an extension can be requested in writing to the executive director. The request must include all documentation demonstrating that closure will take longer than 180 days and that the owner/operator has taken steps and will continue to take steps to prevent threats to human health and environment from the unclosed portions of the site.
- Documented certification by an independent licensed Professional Engineer will be submitted to the TCEQ following completion of final closure certifying completion in accordance with the final closure plan and including all documentation necessary for certification of final closure. A copy of the approved certification from the TCEQ will be placed in the operating record.
- Within 10 days of final completion of closure activities for the Landfill, the owner/operator will submit a certified copy of an Affidavit to the Public to the Executive Director. A copy will also be placed in the operating record. The affidavit will include an updated metes and bounds description of the extent of the disposal areas.
- A certified notation will be recorded on the deed to the property the facility is on that will in perpetuity notify a potential purchaser that the land has previously been used as a landfill. The use of this land will be restricted to the provisions specified in Section 3.9 - Post-Closure Plan. The owner/operator will submit a certified copy of the modified deed to the Executive Director and place a copy in the site operating record within 10 days of final completion of closure activities for the Landfill.

3.8.5 Final Contour Map

30 TAC §330.457(e)(5)

A final contour map depicting the final contours, 100-year floodplain, and establishing top slopes and sideslopes for the McCombs Landfill is provided in Appendix 3E - Site

Layout Plan, Drawing P3-16. No structural designs for collection and conveyance along the top and side slopes (i.e., berms, dikes, chutes) are recommended as the final cover design meets the requirements for soil loss and non-erodible velocities.

3.8.6 Final Closure Costs

30 TAC §330.503

The estimated cost to hire a third party to perform the closure project (for the largest area to ever require final cover, identified in section 3.3.2) can be found in Appendix 3N, Attachment 3 - Closure Cost Estimates.

Additionally, in order to comply with 30 TAC §330.503(b), a copy of the City's current financial assurance cost estimates for the facility are provided in Appendix 3N, Attachment 3.

The Post-Closure Plan has been prepared in compliance with applicable regulations (30 TAC §330.463(b) and 330.465) for the McCombs Landfill. Post-closure care maintenance will begin upon completion of final-closure activities and approval by the TCEQ. This post closure plan includes the following:

- Provisions for groundwater and landfill gas monitoring, leachate collection, and maintenance activities for the final cover system and drainage facilities to be conducted during post-closure care period, and the frequency at which these activities will be performed;
- Provisions for reducing the post-closure care period;
- The name, address, and phone number for the responsible party in charge of the post-closure care activities during the duration of the 30-year post-closure period; and
- Provisions for certification at the completion of the post-closure care period.

3.9.1 Post-Closure Monitoring and Maintenance Activities

The period of post-closure will be 30 years unless approval from TCEQ allows a change in duration. The City of El Paso will maintain the right of entry and all right-of-ways to the facility throughout this period. Maintenance activities include annual site inspections (unless otherwise stated below) with a written summary and will consist of, but are not limited to the following:

- Maintenance and/or remediation activities, as needed, to maintain the integrity and effectiveness of the final cover system, site vegetation, and storm water drainage control systems. Activities may include regrading, addition of soil, seeding, and erosion and sedimentation control structure repairs;
- Control surface run-on and run-off in order to minimize erosion of the final cover system. Activities may include regarding, addition of soil, seeding, and erosion and sedimentation control structure repairs or cleaning;
- Control of undesirable vegetation growth on the final cover system;
- Correct the effects of settlement, subsidence, ponded water, erosion, or other events or failures in as much as these situations are detrimental to the integrity of the closed landfill. Activities may include regarding, addition of soil, seeding, or removal of water or sediment;
- Maintain the integrity of on-site structures, roads, gates and fences;
- Maintain groundwater monitoring in accordance with Section 3.6, Groundwater Sampling and Analysis Plan and 30 TAC §330.401–330.421. The monitoring

frequency shall be semi-annual. Parameters to be monitored will be in accordance with 30 TAC §330.419 unless otherwise approved by the TCEQ;

- Maintain and operate the leachate control system in accordance with Section 3.5, Waste Management Unit Design Plan, Appendix 3I, Leachate and Contaminated Water Plan, and 30 TAC §330.331 and 330.333 unless otherwise approved by the TCEQ and leachate no longer poses a threat to human health and the environment;
- Maintain and operate the landfill gas monitoring system in accordance with Section 3.7, Landfill Gas Management Plan and 30 TAC §330.371. Monitoring frequency shall be quarterly unless otherwise approved by the TCEQ;
- Retain the Site Operating Record and documentation of post-closure care activities, including monitoring results and records of inspections and maintenance performed;
- Maintain the required benchmark and landfill markers; and
- Repair/Replace gas probes, gas extraction wells, leachate collection and removal system components, groundwater monitoring system components as necessary.

3.9.2 Post-Closure Care Period

The length of the post-closure maintenance period may be decreased or increased by the TCEQ. If the Landfill submits documentation, signed by an independent registered professional engineer, that demonstrates that a reduced period will sufficiently protect human health and the environment, the TCEQ may review and approve a decrease in the post-closure care period. If it is determined that an increased duration is necessary to protect human health and the environment, notification will be given to the Landfill prior to any such change by the TCEQ.

Certification of completion of the post-closure care period and voluntary permit revocation will be in accordance with 30 TAC §330.465 upon completion of the post-closure care maintenance period. The Landfill must submit a documented certification, signed by an independent registered professional engineer, verifying the post-closure care has been in accordance with the approved plan. The submittal shall also include all necessary documentation for certification of completion of post-closure care.

3.9.3 Contact for Post-Closure Activities

The following is the current responsible party overseeing the post-closure care maintenance activities for the facility:

The City of El Paso
Environmental Services
7968 San Paulo Drive
El Paso, Texas 79907
Phone: (915) 621-6700
Fax: (915) 621-6711

The person responsible for post-closure care activities is subject to change. In the event there is a change, the TCEQ will be notified.

3.9.4 Post-Closure Land Use

Other than open space, there are no proposed uses or plans at this time for the McCombs Landfill following closure. Any proposed uses will be submitted to the TCEQ for review and approval.

3.9.5 Post-Closure Costs

30 TAC §330.507

The estimated costs associated with post-closure care maintenance of the McCombs Landfill can be found in Appendix 3O - Post-Closure Details.

Additionally, in order to comply with 30 TAC §330.503(b), a copy of the City's current financial assurance cost estimates for the facility are provided in Appendix 3N, Attachment 3.

SAIC®

A Site Development Plan has been provided as Part III of this MPA application submittal as per the regulations set forth in 30 TAC §330.63. The following Section 3.1 provides a narrative which includes the criteria that, in the selection and design of the facility, will provide for the safeguarding of the health, welfare, and physical property of the people and the environment. This is accomplished through consideration of the site geology and soil conditions, drainage, land use, zoning, and adequacy of access roads and highways.

3.1.1 Site History

The Landfill is located approximately 20 miles northeast of downtown El Paso near the intersection of McCombs Road and Stan Roberts (FM 2529). The limits of the facility are approximately defined as McCombs Road to the west, Stan Roberts (FM 2529) to the south, State Highway/County Road 293 to the north, and vacant desert land to the east.

The McCombs Landfill was originally permitted on August 13, 1976 under Permit No. 729 for operation on 25 acres. A permit amendment was issued on May 30, 1984 which increased the total permitted area from 25 acres to 327 acres (327.292 acres in Section 6, Block 80, Township 1, Texas and Pacific Railway Survey, per the site legal description). The facility ceased regular solid waste disposal activities on February 3, 2005 and has only received limited waste since this time from City clean-up projects and storm events. Prior to landfilling operations, the site was owned by Prices Producers, Inc. (Prices). The City of El Paso purchased the property from Prices in September 1954. The site was subsequently leased to El Paso Sand Products to be used for aggregate mining.

Previous landfill activities were confined to approximately 95***.2*** acres ***(74.7 acres unlined and 20.5 acres lined (Phase I/II))*** of land on the southwest quadrant of the permitted facility ***as well as existing Sector A (17.4 acres)***. A paved access road just north of the intersection of McCombs Road and Stan Roberts (FM 2529) provides access to the landfill facility.

3.1.2 Permit Amendment Overview

This MPA application develops a vertical expansion of the Landfill from a current maximum height of 4,125 feet MSL to 4,305 feet MSL. This corresponds to an increase in capacity of ***46,468,693*** ~~46,148,275~~ CY from a previously permitted volume of 22,348,549 CY to a new permitted volume of ***68,817,242*** ~~68,496,824~~ CY. The expansion will apply to all areas of the landfill, including the previously-filled 95***.2*** acre area in the southwest corner. ***An area of 64.0***~~78~~ acres ~~of this 95 acre area~~ will have a piggyback liner, as described in Section 3.4 ***and portrayed on drawing P3-28B***

in Appendix 3G, Attachment 4. ***An area of 11.5 acres will not receive liner as they are the sideslopes of the expansion area and will not receive any MSW waste. An area of 20.5 acres***~~The remaining 17-acres~~ (currently Subtitle D lined ***Phase I/II***) will continue to be used for MSW disposal (including RACM disposal as described in Section 4.9.22), but at an increased elevation. ***The additional acreage between the previous southwest area (95.2-acres) and the new total acreage in the southwest area (96.0-acres)is the acreage that previously existed between the unlined and lined areas (Phase I/II).***

This vertical expansion will not involve excavation below the previous permitted elevations for the Landfill.

This MPA also increases the ***property***~~permitted~~/facility area from 327.292 acres (as described in Section 3.1.1) to 346.74 acres within Section 6, Block 80, Township 1, Texas and Pacific Railway Survey. An updated metes and bounds is provided in Appendix 1C. ***It should be noted that the increase is only for the property/facility boundary and the permitted waste footprint size is not increasing.***

3.1.3 Geology and Soil Conditions

A detailed discussion of the geology and soil conditions at the Landfill can be found in Appendix 3K – Geology of this MPA application.

The Landfill is located on deposits of the Hueco Bolson, probably Camp Rice Formation. The Camp Rice Formation unconformably overlies the Fort Hancock Formation and is primarily composed of gravel, sand, silt and occasional discontinuous lenses of volcanic ash. The Camp Rice Formation is composed of two basic subdivisions, a fluvial and a piedmont facies. The fluvial facies is chiefly sand to pebbly river-channel deposits with subordinate fine-grained overbank units. This facies thickens toward the bolson axes and commonly wedges out against the piedmont facies. The permitted landfill area is probably underlain by fluvial deposits of the Camp Rice Formation.

The Hueco Bolson deposits primarily consist of clay, sand, and gravel, with some caliche. The landfill site is underlain by Tertiary and Quaternary basin (bolson) deposits, overlain by areas of gravel and caliche rimrock. Recent Quaternary alluvial deposits are also present in the landfill vicinity in topographically low areas.

In general, the relatively clean sand and silty sand are non-plastic, while clayey sand ranges from low to high plasticity. Permeability tests were not considered necessary based on the soil types encountered during the site characterization. Estimated coefficient of permeability are between 0.01 and 0.04 centimeters per second (cm/sec).

3.1.4 Surface Water and Drainage

The complete Facility Surface Water Drainage Report can be found in Section 3.3 of this MPA application submittal.

The stormwater on site is directed away from active portions of the landfill by ditches designed for the 25-year 24-hour storm event. The ditches direct water to the three

onsite stormwater retention ponds (A, D, and E). These ponds are designed to hold the 100-year 24-hour storm event as well as contingency storage for sediment.

Four ponds will exist in the final cover condition (A, B, C, and E). Perimeter ditches will be constructed as the intermediate elevations increase above existing grade. These ditches will direct water to the retention ponds where they will retain the 100 year 24-hour event and sediment. The landfill will provide care and management, both during construction and long term, of soil erosion and control of sediment due to surface water.

The care and management of soil erosion and sedimentation is outlined in Appendix 3B – Surface Water Drainage Analysis. The facility will prevent discharge of pollutants to waters of the state. There are no waters of the United States or Corps of Engineers' jurisdictional waters of the state on site therefore no Section 404 permit is required. The McCombs Landfill submitted a notice of intent (NOI) to comply with the TPDES Multi-Sector General Permit relating to stormwater discharge and received Permit No. TXR05L795 from the TCEQ on October 28, 2011. A copy of this permit is included in Appendix 2D – TPDES Multi-Sector General Permit.

3.1.5 Land Use and Zoning

A detailed analysis of the land use and zoning of the area immediately surrounding the Landfill is included in Appendix 2B – Land Use Analysis of this MPA application. As described in this analysis, the Landfill is located within the City limits approximately 10 miles northeast of downtown, and lies within 500 feet of the Texas-New Mexico border.

In Texas, the land surrounding the landfill is predominately zoned for light or heavy industrial use, or as a ranch or farm district. From El Paso county plat records and from a visual survey conducted on November 10, 2010, the land immediately surrounding the landfill is primarily owned by the City and is mostly undeveloped.

In New Mexico, the surrounding land use is zoned as a Performance District (PD). According to the Dona Ana County Land Use Regulations and Zoning Ordinance, the purpose of zoning a region as a PD is to allow flexibility for land use activities in the rural areas of the County by acting as a mixed use zone.

No schools, licensed day-care facilities, churches, hospitals, cemeteries, or lakes were identified through visual survey or parcel records within one mile of the Landfill. One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.

3.1.6 Access Roads and Highways

A traffic impact analysis (TIA) completed by the City of El Paso has been included in Appendix 2C – Traffic Analysis of this MPA application.

The TIA explored the impact of the background traffic growth with the addition of the Landfill traffic to determine the level of mobility (LOM) for McCombs Road, the main access road for the site. As stated in the analysis, McCombs Road between State Line Road and Stan Roberts Sr. Road is projected to reach "serious" LOM by the year 2040 as a result of the continuing background traffic growth.

With the addition of traffic generated by the Landfill, the volume to capacity (V/C) ratio increases, but does not result in worse LOM rankings. Because the Landfill does not adversely affect the LOM ranking for the roadway, it is recommended that the improvements to McCombs Road are implemented as recommended in the City's Metropolitan Transportation Plan (MTP).

Section 3.1
SITE DEVELOPMENT PLAN NARRATIVE
30 TAC §330.63(a)

A Site Development Plan has been provided as Part III of this MPA application submittal as per the regulations set forth in 30 TAC §330.63. The following Section 3.1 provides a narrative which includes the criteria that, in the selection and design of the facility, will provide for the safeguarding of the health, welfare, and physical property of the people and the environment. This is accomplished through consideration of the site geology and soil conditions, drainage, land use, zoning, and adequacy of access roads and highways.

3.1.1 Site History

The Landfill is located approximately 20 miles northeast of downtown El Paso near the intersection of McCombs Road and Stan Roberts (FM 2529). The limits of the facility are approximately defined as McCombs Road to the west, Stan Roberts (FM 2529) to the south, State Highway/County Road 293 to the north, and vacant desert land to the east.

The McCombs Landfill was originally permitted on August 13, 1976 under Permit No. 729 for operation on 25 acres. A permit amendment was issued on May 30, 1984 which increased the total permitted area from 25 acres to 327 acres (327.292 acres in Section 6, Block 80, Township 1, Texas and Pacific Railway Survey, per the site legal description). The facility ceased regular solid waste disposal activities on February 3, 2005 and has only received limited waste since this time from City clean-up projects and storm events. Prior to landfilling operations, the site was owned by Prices Producers, Inc. (Prices). The City of El Paso purchased the property from Prices in September 1954. The site was subsequently leased to El Paso Sand Products to be used for aggregate mining.

Previous landfill activities were confined to approximately 95 acres of land on the southwest quadrant of the permitted facility. A paved access road just north of the intersection of McCombs Road and Stan Roberts (FM 2529) provides access to the landfill facility.

3.1.2 Permit Amendment Overview

This MPA application ***develops a vertical expansion of*** ~~proposes to vertically expand~~ the Landfill from a current maximum height of 4,125 feet MSL to 4,305 feet MSL. This corresponds to an increase in capacity of 46,148,275 CY from a previously permitted volume of 22,348,549 CY to a new permitted volume of 68,496,824 CY. The expansion will apply to all areas of the landfill, including the previously-filled 95 acre area in the southwest corner. 78-acres of this 95-acre area will have a piggyback liner, as described in Section 3.4. The remaining 17-acres (currently Subtitle D lined)

will continue to be used for MSW disposal (including RACM disposal as described in Section 4.9.22), but at an increased elevation.

This vertical expansion will not involve excavation below the ***previous*** ~~currently~~ permitted elevations for the Landfill ~~(Permitted under 729A)~~.

This MPA also increases the permitted/facility area from 327.292 acres (as described in Section 3.1.1) to 346.74 acres within Section 6, Block 80, Township 1, Texas and Pacific Railway Survey. An updated metes and bounds is provided in Appendix 1C.

3.1.3 Geology and Soil Conditions

A detailed discussion of the geology and soil conditions at the Landfill can be found in Appendix 3K – Geology of this MPA application.

The Landfill is located on deposits of the Hueco Bolson, probably Camp Rice Formation. The Camp Rice Formation unconformably overlies the Fort Hancock Formation and is primarily composed of gravel, sand, silt and occasional discontinuous lenses of volcanic ash. The Camp Rice Formation is composed of two basic subdivisions, a fluvial and a piedmont facies. The fluvial facies is chiefly sand to pebbly river-channel deposits with subordinate fine-grained overbank units. This facies thickens toward the bolson axes and commonly wedges out against the piedmont facies. The permitted landfill area is probably underlain by fluvial deposits of the Camp Rice Formation.

The Hueco Bolson deposits primarily consist of clay, sand, and gravel, with some caliche. The landfill site is underlain by Tertiary and Quaternary basin (bolson) deposits, overlain by areas of gravel and caliche rimrock. Recent Quaternary alluvial deposits are also present in the landfill vicinity in topographically low areas.

In general, the relatively clean sand and silty sand are non-plastic, while clayey sand ranges from low to high plasticity. Permeability tests were not considered necessary based on the soil types encountered during the site characterization. Estimated coefficient of permeability are between 0.01 and 0.04 centimeters per second (cm/sec).

3.1.4 Surface Water and Drainage

The complete Facility Surface Water Drainage Report can be found in Section 3.3 of this MPA application submittal.

The stormwater on site is directed away from active portions of the landfill by ditches designed for the 25-year 24-hour storm event. The ditches direct water to the three onsite stormwater retention ponds (A, D, and E). These ponds are designed to hold the 100-year 24-hour storm event as well as contingency storage for sediment.

Four ponds will exist in the final cover condition (A, B, C, and E). Perimeter ditches will be constructed as the intermediate elevations increase above existing grade. These ditches will direct water to the retention ponds where they will retain the 100 year 24-hour event and sediment. The landfill will provide care and management,

both during construction and long term, of soil erosion and control of sediment due to surface water.

The care and management of soil erosion and sedimentation is outlined in Appendix 3B – Surface Water Drainage Analysis. The facility will prevent discharge of pollutants to waters of the state. There are no waters of the United States or Corps of Engineers' jurisdictional waters of the state on site therefore no Section 404 permit is required. The McCombs Landfill submitted a notice of intent (NOI) to comply with the TPDES Multi-Sector General Permit relating to stormwater discharge and received Permit No. TXR05L795 from the TCEQ on October 28, 2011. A copy of this permit is included in Appendix 2D – TPDES Multi-Sector General Permit.

3.1.5 Land Use and Zoning

A detailed analysis of the land use and zoning of the area immediately surrounding the Landfill is included in Appendix 2B – Land Use Analysis of this MPA application. As described in this analysis, the Landfill is located within the City limits approximately 10 miles northeast of downtown, and lies within 500 feet of the Texas-New Mexico border.

In Texas, the land surrounding the landfill is predominately zoned for light or heavy industrial use, or as a ranch or farm district. From El Paso county plat records and from a visual survey conducted on November 10, 2010, the land immediately surrounding the landfill is primarily owned by the City and is mostly undeveloped.

In New Mexico, the surrounding land use is zoned as a Performance District (PD). According to the Dona Ana County Land Use Regulations and Zoning Ordinance, the purpose of zoning a region as a PD is to allow flexibility for land use activities in the rural areas of the County by acting as a mixed use zone.

No schools, licensed day-care facilities, churches, hospitals, cemeteries, or lakes were identified through visual survey or parcel records within one mile of the Landfill. One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.

3.1.6 Access Roads and Highways

A traffic impact analysis (TIA) completed by the City of El Paso has been included in Appendix 2C – Traffic Analysis of this MPA application.

The TIA explored the impact of the background traffic growth with the addition of the Landfill traffic to determine the level of mobility (LOM) for McCombs Road, the main access road for the site. As stated in the analysis, McCombs Road between State Line Road and Stan Roberts Sr. Road is projected to reach "serious" LOM by the year 2040 as a result of the continuing background traffic growth.

With the addition of traffic generated by the Landfill, the volume to capacity (V/C) ratio increases, but does not result in worse LOM rankings. Because the Landfill does

not adversely affect the LOM ranking for the roadway, it is recommended that the improvements to McCombs Road are implemented as recommended in the City's Metropolitan Transportation Plan (MTP).

Section 3.1
SITE DEVELOPMENT PLAN NARRATIVE
30 TAC §330.63(a)

A Site Development Plan has been provided as Part III of this MPA application submittal as per the regulations set forth in 30 TAC §330.63. The following Section 3.1 provides a narrative which includes the criteria that, in the selection and design of the facility, will provide for the safeguarding of the health, welfare, and physical property of the people and the environment. This is accomplished through consideration of the site geology and soil conditions, drainage, land use, zoning, and adequacy of access roads and highways.

3.1.1 Site History

The Landfill is located approximately 20 miles northeast of downtown El Paso near the intersection of McCombs Road and Stan Roberts (FM 2529). The limits of the facility are approximately defined as McCombs Road to the west, Stan Roberts (FM 2529) to the south, State Highway/County Road 293 to the north, and vacant desert land to the east.

The McCombs Landfill was originally permitted on August 13, 1976 under Permit No. 729 for operation on 25 acres. A permit amendment was issued on May 30, 1984 which increased the total permitted area from 25 acres to 327 acres (327.292 acres in Section 6, Block 80, Township 1, Texas and Pacific Railway Survey, per the site legal description). The facility ceased regular solid waste disposal activities on February 3, 2005 and has only received limited waste since this time from City clean-up projects and storm events. Prior to landfilling operations, the site was owned by Prices Producers, Inc. (Prices). The City of El Paso purchased the property from Prices in September 1954. The site was subsequently leased to El Paso Sand Products to be used for aggregate mining.

Previous landfill activities were confined to approximately 95 acres of land on the southwest quadrant of the permitted facility. A paved access road just north of the intersection of McCombs Road and Stan Roberts (FM 2529) provides access to the landfill facility.

3.1.2 Permit Amendment Overview

This MPA application proposes to vertically expand the Landfill from a current maximum height of 4,125 feet MSL to 4,305 feet MSL. This corresponds to an increase in capacity of 46,148,275 CY from a previously permitted volume of 22,348,549 CY to a new permitted volume of 68,496,824 CY. The expansion will apply to all areas of the landfill, including the previously-filled 95 acre area in the southwest corner. 78-acres of this 95-acre area will have a piggyback liner, as described in Section 3.4. The remaining 17-acres (currently Subtitle D lined) will

continue to be used for MSW disposal (including RACM disposal as described in Section 4.9.22), but at an increased elevation.

This vertical expansion will not involve excavation below ***the*** ~~what is~~ currently permitted ***elevations*** for the Landfill ***(Permitted under 729A)***.

3.1.3 Geology and Soil Conditions

A detailed discussion of the geology and soil conditions at the Landfill can be found in Appendix 3K – Geology of this MPA application.

The Landfill is located on deposits of the Hueco Bolson, probably Camp Rice Formation. The Camp Rice Formation unconformably overlies the Fort Hancock Formation and is primarily composed of gravel, sand, silt and occasional discontinuous lenses of volcanic ash. The Camp Rice Formation is composed of two basic subdivisions, a fluvial and a piedmont facies. The fluvial facies is chiefly sand to pebbly river-channel deposits with subordinate fine-grained overbank units. This facies thickens toward the bolson axes and commonly wedges out against the piedmont facies. The permitted landfill area is probably underlain by fluvial deposits of the Camp Rice Formation.

The Hueco Bolson deposits primarily consist of clay, sand, and gravel, with some caliche. The landfill site is underlain by Tertiary and Quaternary basin (bolson) deposits, overlain by areas of gravel and caliche rimrock. Recent Quaternary alluvial deposits are also present in the landfill vicinity in topographically low areas.

In general, the relatively clean sand and silty sand are non-plastic, while clayey sand ranges from low to high plasticity. Permeability tests were not considered necessary based on the soil types encountered during the site characterization. Estimated coefficient of permeability are between 0.01 and 0.04 centimeters per second (cm/sec).

3.1.4 Surface Water and Drainage

The complete Facility Surface Water Drainage Report can be found in Section 3.3 of this MPA application submittal.

The stormwater on site is directed away from active portions of the landfill by ditches designed for the 25-year 24-hour storm event. The ditches direct water to the three onsite stormwater retention ponds (A, D, and E). These ponds are designed to hold the 100-year 24-hour storm event as well as contingency storage for sediment.

Four ponds will exist in the final cover condition (A, B, C, and E). Perimeter ditches will be constructed as the intermediate elevations increase above existing grade. These ditches will direct water to the retention ponds where they will retain the 100 year 24-hour event and sediment. The landfill will provide care and management, both during construction and long term, of soil erosion and control of sediment due to surface water.

The care and management of soil erosion and sedimentation is outlined in Appendix 3B – Surface Water Drainage Analysis. The facility will prevent discharge of pollutants to waters of the state. There are no waters of the United States or Corps of

Engineers' jurisdictional waters of the state on site therefore no Section 404 permit is required. The McCombs Landfill submitted a notice of intent (NOI) to comply with the ~~NPDES~~ ***TPDES Multi-Sector*** General Permit relating to stormwater discharge and received Permit No. ~~TXR05E214~~ ***TXR05L795*** from the ~~United States Environmental Protection Agency (U.S. EPA) in June of 1998~~ ***TCEQ on October 28, 2011***. A copy of this permit is included in Appendix 2D – ***TPDES Multi-Sector General Permit*** ~~NPDES Certification~~.

3.1.5 Land Use and Zoning

A detailed analysis of the land use and zoning of the area immediately surrounding the Landfill is included in Appendix 2B – Land Use Analysis of this MPA application. As described in this analysis, the Landfill is located within the City limits approximately 10 miles northeast of downtown, and lies within 500 feet of the Texas-New Mexico border.

In Texas, the land surrounding the landfill is predominately zoned for light or heavy industrial use, or as a ranch or farm district. From El Paso county plat records and from a visual survey conducted on November 10, 2010, the land immediately surrounding the landfill is primarily owned by the City and is mostly undeveloped.

In New Mexico, the surrounding land use is zoned as a Performance District (PD). According to the Dona Ana County Land Use Regulations and Zoning Ordinance, the purpose of zoning a region as a PD is to allow flexibility for land use activities in the rural areas of the County by acting as a mixed use zone.

No schools, licensed day-care facilities, churches, ***hospitals,*** ~~or~~ cemeteries***, or lakes*** were identified through visual survey or parcel records within one mile of the Landfill. ***One man-made pond was identified approximately 1,800-feet east of the facility. The pond is part of the CEMEX quarry area for stormwater control and is dry most of the year. It should also be noted that due to ongoing quarry operations, the size, number, and location of man-made ponds may vary at different times during mining operations.***

3.1.6 Access Roads and Highways

A traffic impact analysis (TIA) completed by the City of El Paso has been included in Appendix 2C – Traffic Analysis of this MPA application.

The TIA explored the impact of the background traffic growth with the addition of the Landfill traffic to determine the level of mobility (LOM) for McCombs Road, the main access road for the site. As stated in the analysis, McCombs Road between State Line Road and Stan Roberts Sr. Road is projected to reach "serious" LOM by the year 2040 as a result of the continuing background traffic growth.

With the addition of traffic generated by the Landfill, the volume to capacity (V/C) ratio increases, but does not result in worse LOM rankings. Because the Landfill does not adversely affect the LOM ranking for the roadway, it is recommended that the improvements to McCombs Road are implemented as recommended in the City's Metropolitan Transportation Plan (MTP).

3.2.1 Facility Access and Site Security

All public access will be controlled to minimize unauthorized traffic, illegal dumping and exposure to hazardous materials. Access to the Landfill will be restricted by existing barbed wire fencing along the perimeter of the facility as well as a locking gate at the facility entrance. These measures will act as deterrents for unauthorized entry during and outside of normal Landfill operating hours. Existing earthen berms along the western and northern boundaries of the Landfill also act as natural deterrents and provide a method of visual screening. ***The City will install debris netting as needed along the facility boundary.***

During times in which the Landfill is accepting waste, access to the Landfill will be restricted to designated Landfill personnel, approved waste haulers, and citizens who have been properly identified by Landfill personnel. Citizens will be directed to a public drop-off area (PDA) and may only be granted access to the working face under the direction of Landfill staff.

3.2.2 Waste Movement

As noted in Section 2.2.1, the Landfill will accept MSW as defined by 30 TAC §330.3***, inert construction and demolition waste (Class 3 like),*** and several types of special wastes. Special wastes accepted include Class II industrial waste and municipal commercial waste such as treated medical waste, processed grease/grit trap waste, dead animals, slaughterhouse wastes, and petroleum-product or crude oil contaminated soil. The Landfill also intends to accept RACM. The specific procedures for acceptance, processing and disposal of these wastes are described in Part IV – Site Operating Plan of this MPA application submittal.

Drawing P3-1 shows the general waste movement flow chart for the Landfill. As can be seen from this drawing, all waste will enter the Landfill through the site entrance and will be screened and documented by the scale house attendant. The scale house attendant will be knowledgeable in the types of waste that are accepted and not accepted at the Landfill and will direct each waste hauler to the appropriate area for processing and disposal. Landfill personnel will have the authority to reject any waste that cannot be accepted at the facility. Haulers identified as sources of identified prohibited waste will be responsible for removing the prohibited waste from the Landfill.

In the event that unauthorized waste is not discovered until after the waste hauler has left the Landfill, the waste will be separated and controlled as necessary. Landfill personnel will make an effort to identify the source of the unauthorized waste and have the waste hauler return to the site to remove the waste. If a positive identification cannot be achieved, Landfill personnel will notify the TCEQ and seek guidance on

practical disposal of the waste. A record of the removal of unauthorized waste will be kept in the Site Operating Record.

3.2.2.1 Public Drop-Off Area

All residents and some commercial haulers will be directed to the PDA to dispose of wastes in roll-off containers. Trained Landfill personnel will be positioned at the public drop-off area and working face to visually screen for prohibited items.

3.2.2.2 Bulky Items Storage

Customers disposing of bulky items and white goods will be directed towards the public drop-off area for unloading (as identified on Drawing P3-17). Acceptable bulky items and white goods include automobiles, metal tanks, large metal pieces, and household appliances that have had all chlorinated fluorocarbons (CFCs) removed in accordance with 40 CFR §82.156(f). These items will be recycled by a permitted salvage company under contract with the City.

3.2.3 Sanitation and Water Pollution Control

As described in Section 3.3 – Facility Surface Water Drainage Report, the Landfill will retain all stormwater collected from the property in on-site collection ponds. These ponds are designed to hold the runoff from the facility during the 100-year storm event with 25 percent emergency capacity as well as the volume of silt generated from the drainage area.

Stormwater runoff from the ***covered*** waste mass ***(i.e., not active)*** will be collected in v-ditches around the perimeter of the landfill. These v-ditches are designed to convey the 25-year storm event for each drainage basin and will direct the stormwater runoff into existing stormwater retention ponds. ***The retention ponds on site do not have an outlet structure and will drain down via infiltration (or evaporation). Stormwater runoff from the active waste mass will be contained with site run-on/runoff berms as described in Appendix 3I and will be treated as leachate.***

Containment areas for the public drop-off area are identified on the Moreno Cardenas Drawing C13 (Appendix 3E). Additionally calculations for storage capacity as well as high water and top elevation for the containment ponds are provided on the drawing.

3.2.3.1 Public Drop-Off Area and Bulky Items Storage

Stormwater from the PDA will be conveyed to stormwater retention ponds located in the entrance facility area (Drawing P3-17 in Appendix 3E). Interior roads leading from the entrance of the facility to the grade-separated PDA will be paved using asphalt. The area under the roll-off containers will be paved with concrete. Both the asphalt and the concrete will be sloped to prevent ponding and to encourage the conveyance of water to the stormwater retention ponds.

3.2.4 Endangered Species Protection

Correspondence with the Texas Parks and Wildlife Department and the U.S. Fish and Wildlife Service regarding the identification and protection of endangered and threatened species is provided in Section 2.10 and Appendix 2F. Landfill staff will follow the recommendations specified if a species identified is encountered during excavation or filling operations.

3.2.1 Facility Access and Site Security

All public access will be controlled to minimize unauthorized traffic, illegal dumping and exposure to hazardous materials. Access to the Landfill will be restricted by existing barbed wire fencing along the perimeter of the facility as well as a locking gate at the facility entrance. These measures will act as deterrents for unauthorized entry during and outside of normal Landfill operating hours. Existing earthen berms along the western and northern boundaries of the Landfill also act as natural deterrents and provide a method of visual screening.

During times in which the Landfill is accepting waste, access to the Landfill will be restricted to designated Landfill personnel, approved waste haulers, and citizens who have been properly identified by Landfill personnel. Citizens will be directed to a public drop-off area (PDA) and may only be granted access to the working face under the direction of Landfill staff.

3.2.2 Waste Movement

As noted in Section 2.2.1, the Landfill will accept MSW as defined by 30 TAC §330.3 and several types of special wastes. Special wastes accepted include Class II industrial waste and municipal commercial waste such as treated medical waste, processed grease/grit trap waste, dead animals, slaughterhouse wastes, and petroleum-product or crude oil contaminated soil. The Landfill also intends to accept RACM. The specific procedures for acceptance, processing and disposal of these wastes are described in Part IV – Site Operating Plan of this MPA application submittal.

Drawing P3-1 shows the general waste movement flow chart for the Landfill. As can be seen from this drawing, all waste will enter the Landfill through the site entrance and will be screened and documented by the scale house attendant. The scale house attendant will be knowledgeable in the types of waste that are accepted and not accepted at the Landfill and will direct each waste hauler to the appropriate area for processing and disposal. Landfill personnel will have the authority to reject any waste that cannot be accepted at the facility. Haulers identified as sources of identified prohibited waste will be responsible for removing the prohibited waste from the Landfill.

In the event that unauthorized waste is not discovered until after the waste hauler has left the Landfill, the waste will be separated and controlled as necessary. Landfill personnel will make an effort to identify the source of the unauthorized waste and have the waste hauler return to the site to remove the waste. If a positive identification cannot be achieved, Landfill personnel will notify the TCEQ and seek guidance on practical disposal of the waste. A record of the removal of ***un***authorized waste will be kept in the Site Operating Record.

3.2.2.1 Public Drop-Off Area

All residents and some commercial haulers will be directed to the PDA to dispose of wastes in roll-off containers. Trained Landfill personnel will be positioned at the public drop-off area and working face to visually screen for prohibited items.

3.2.2.2 Bulky Items Storage

Customers disposing of bulky items and white goods will be directed towards the public drop-off area for unloading ***(as identified on Drawing P3-17)***. Acceptable bulky items and white goods include automobiles, metal tanks, large metal pieces, and household appliances that have had all chlorinated fluorocarbons (CFCs) removed in accordance with 40 CFR §82.156(f). These items will be recycled by a permitted salvage company under contract with the City.

3.2.3 Sanitation and Water Pollution Control

As described in Section 3.3 – Facility Surface Water Drainage Report, the Landfill will retain all stormwater collected from the property in on-site collection ponds. These ponds are designed to hold the runoff from the facility during the 100-year storm event with 25 percent emergency capacity as well as the volume of silt generated from the drainage area.

Stormwater runoff from the waste mass will be collected in v-ditches around the perimeter of the landfill. These v-ditches are designed to convey the 25-year storm event for each drainage basin and will direct the stormwater runoff into existing stormwater retention ponds.

Containment areas for the public drop-off area are identified on the Moreno Cardenas Drawing C13 (Appendix 3E). Additionally calculations for storage capacity as well as high water and top elevation for the containment ponds are provided on the drawing.

3.2.3.1 Public Drop-Off Area and Bulky Items Storage

Stormwater from the PDA will be conveyed to stormwater retention ponds located in the entrance facility area (Drawing P3-17 in Appendix 3E). Interior roads leading from the entrance of the facility to the grade-separated PDA will be paved using asphalt. The area under the roll-off containers will be paved with concrete. Both the asphalt and the concrete will be sloped to prevent ponding and to encourage the conveyance of water to the stormwater retention ponds.

3.2.4 Endangered Species Protection

~~As discussed in Section 2.10, the American Peregrine Falcon may utilize the area around the Landfill for feeding or may pass through during migration. This species remains a protected species in the State of Texas, but has been removed from the USFWS endangered species list as of August 25, 1999. Documentation of the~~

~~removal of the American Peregrine Falcon from the endangered species list has been provided in Appendix 2F – Endangered Species Documentation.~~

~~According to the ***1982*** USFWS letter included in Appendix 2F, it is unlikely that the Landfill will have any adverse effects on the American Peregrine Falcon. However, if Landfill personnel observe the species on Landfill property, they are advised to do the following:~~

~~1. Avoid contact with the bird;~~

~~2. Temporarily halt or move site operations to an area away from the bird's location to prevent disrupting the bird's activities while feeding or passing by the site;~~

~~3. Wait until the bird abandons the site on its own will; and~~

~~4. Resume normal site operations once the bird has taken flight.~~

Correspondence with the Texas Parks and Wildlife Department and the U.S. Fish and Wildlife Service regarding the identification and protection of endangered and threatened species is provided in Section 2.10 and Appendix 2F. Landfill staff will follow the recommendations specified if a species identified is encountered during excavation or filling operations.

This report has been prepared consistent with the requirements of 30 TAC §330.301-330.307. Included in this report are pre-developed, existing, and developed drainage area maps along with erosion control measures and drainage control features. Also provided are hydrologic calculations for pre-developed, existing and developed Landfill conditions. These calculations demonstrate that there is no significant alteration in drainage patterns due to the development of the Landfill. During all phases of construction, the Facility will be constructed, maintained and operated to ensure that run-on and runoff during the 25-year storm event is controlled within the site.

3.3.1 Drainage Analysis

3.3.1.1 Concepts and Methods

The hydrologic and hydraulic methods employed in this report are consistent with TCEQ regulations. The criterion used is located in the Texas Department of Transportation Bridge Division Hydraulic Design Manual (DOT Drainage Manual). The hydrologic and hydraulic analyses were performed using the Rational Method and Manning's Equation respectively. The Rational Method is based on the maximum flow rate from a drainage area being produced by flows at a given rainfall intensity contributing to the flow at the point of discharge.

The Rational Method equation (in English Units) is as follows:

$Q = CIA$

Where:

Q = Flow rate of Discharge, in cubic feet per second (cfs)

C = Runoff Coefficient, which is unitless

I = Rainfall Intensity, in inches per hour (in/hr)

A = Drainage Area, in acres

The Intensity (I) for a rainstorm is determined from the formula (in English units):

$I = b/[T_c+d)^e]$

Where:

I = Rainfall Intensity, in inches per hour

T_c = Time of Concentration, in minutes (Calculated using the Watershed Lag Method)

e,b,d = Coefficients for specific frequencies, unitless

The runoff coefficient, C, is based on the topography, land cover, and land development of the contributing drainage area. Values of C from the DOT Drainage Manual are shown in Appendix 3B, Attachment 1 – Stormwater Calculations.

The rainfall intensity, I, is based on the time of concentration, T_c, in minutes. This is the time it takes the runoff to flow from the furthest point in the drainage area to the point of discharge.

The coefficients used for El Paso County, as obtained from the DOT Drainage Manual are shown in Appendix 3B, Attachment 1 – Stormwater Calculations.

The 24-hr, 25-yr storm event was used for the design of conveyance facilities and the 24-hr, 100-yr storm event was used for the design of ponding facilities and to check overtopping of conveyance facilities.

The volume of runoff for each drainage sub-basin was found using the NRCS Runoff Curve Number Method as discussed in the DOT Drainage Manual.

The NRCS method is expressed by the following equation (in English units):

$S = (1000/CN)-10$

Where:

S = Potential Maximum Retention (inches)

CN = Curve Number

Runoff Depth is determined from the formula (in English units):

$R = [(P-0.2S)^2]/[P+0.8S]$

Where:

R = Runoff Depth (inches)

P = Precipitation (inches)

A curve number of 68 was used for existing conditions, representing range land conditions. The closed Landfill with the rock armoring was given a conservative curve number of 73 for final developed conditions. The precipitation for the design events as discussed in the DOT drainage manual can be seen Appendix 3B, Attachment 1 – Stormwater Calculations.

3.3.1.2 Existing Conditions

The McCombs Landfill is an existing municipal solid waste disposal facility located in Section 6, Block 80, Township 1, within the city limits of El Paso, at the intersection of McCombs Road and FM 2529 (Stan Roberts Sr. Road). The site covers 347 acres and the surrounding areas are largely undeveloped. Located west of McCombs Road is the Public Service Board - El Paso Water Utilities' Sludge Monofill.

The soils in the Landfill area are predominantly Turney-Berino Association, moderately deep over soft caliche, in the Hueco Bolson. The soils are characterized as moderately permeable, having high water-holding capacity, and having a slow runoff

rate. Caliche covers the entire Bolson surface and ranges in thicknesses of immeasurable to 8 feet thick.

Pre-Developed drainage patterns and flow rates are shown on Drawing P3-3 – Pre-developed Drainage Conditions, in Appendix 3C. This drawing and drainage discharge values are from the permit dated April 2002, by Moreno Cardenas and remain the same in the Permit Modification dated April 2009 by Parkhill, Smith and Cooper, Inc. (PSC). The existing drainage patterns and flow rates are shown on Drawing P3-4 - Existing Drainage Conditions, in Appendix 3C. It should be noted that the existing drainage patterns have been updated to include the 19.4 acre site facilities drainage area.

Stormwater runoff is collected in a v-ditch around the perimeter of the existing Landfill units and is directed into one of the site stormwater ponds. Runoff generated to the north and east of the existing Landfill is captured in the mined pit area. Some of the runoff in the northwest corner continues to the site of existing Retention Pond A. Runoff generated to the west and south of the existing Landfill area is conveyed into existing Retention Pond D (located west of the existing fee house) and existing Retention Pond E (located in the southeastern corner of the developed Landfill area). Stormwater from the 19.4 acre site entrance facilities area (existing conditions) generally flows to natural low lying areas infiltrates.

Intermediate and long term erosion stability of this site will be dependent upon the implementation of both structural and non-structural best management practices (BMPs) which are also discussed in Appendix 3B – Surface Water Drainage Analysis.

3.3.1.3 Developed Conditions

The Final Drainage Conditions plan, provided in Appendix 3C, Drawing P3-6 shows the final developed conditions. The final contours include four ponds to break up drainage areas (the existing Retention Ponds A and E, and Ponds B and C), and in effect reduce sheet flow and minimize erosion. Existing Pond D is no longer needed as that area is filled to grade and flow is conveyed in a v-ditch to Pond E. Also, the final drainage conditions plan for the site entrance facilities area is provided as Drawing C-13 in Appendix 3E. Stormwater from the site entrance facilities area will be contained in one of six onsite detention areas (labeled as DA-1 through DA-6). All runoff from the site will be contained in onsite retention basins.

A total of eight drainage sub-areas are included in the developed drainage conditions plan as shown on Drawing P3-6 - Final Drainage Conditions. Peak flow rates were calculated for each sub-area and are shown on a table within the drawing. Calculations for peak flow rates are included in Appendix 3B, Attachment 1 – Stormwater Calculations.

Stormwater runoff down the side slopes will be captured by a v-ditch, and directed to one of the four ponds. The perimeter drainage system of v-ditches is designed to convey the 25-yr storm event for each drainage basin. All ditches have also been checked to ensure no overtopping occurs in the 100-yr storm event. Calculations for the perimeter ditch designs are provided in Appendix 3B, Attachment 2 – Ditch Calculations. The earthen v-ditches range in depth from 1.71 to 2.26 feet in depth

with 3H:1V side slopes which includes at least 25% depth of freeboard. Velocities in the ditches range from 3.42 to 6.74 feet per second, as shown in Appendix 3B, Attachment 2 – Ditch Calculations. The ditches with velocities exceeding 4.0 feet per second will require erosion protection, according to maximum non-erodible velocities as published in the USDA-SCS Engineering Field Manual, as outlined in a table on the Final Drainage Conditions drawing (Drawing P3-6).

Culverts will be required to convey water from the existing stormwater Retention Pond E to Pond C, as shown on the Final Drainage Conditions drawing. The culverts were sized by Moreno Cardenas using the Heasted Methods Flowmaster program and are provided in Appendix 3B, Attachment 3. The final drainage conditions of the updated closure plan have been evaluated to ensure the culverts sized previously are adequate. The culverts can be seen on the Final Drainage Conditions drawing and the details as provided previously by Moreno Cardenas are provided on Drawings P3-9 and P3-10 in Appendix 3C.

There are two future retention ponds (B and C) and two existing retention ponds (A and E) for the McCombs Landfill final conditions. The ponds are designed to hold the runoff from the 100-yr storm event, 25% emergency capacity, and silt volume (0.012 ac-ft/acre) generated from the drainage area. Pond A is located in the northwest corner of the site within the 100-year floodplain and retains water from drainage areas DEV-2, DEV-3 and DEV-4. See Section 3.3.2 for a discussion of the 100-Year Floodplain area. This area is not regulated under the Section 404 provisions of the Clean Water Act and the Department of the Army permit is not required. A letter from the Department of the Army, date July 2002, is provided in Appendix 3B, Attachment 4. Pond B is located in the northeast corner of the site and retains water from drainage areas DEV-5 and DEV-6, which includes some minimal offsite run-on storm water from just outside the east property boundary. Pond C is located in the southeast corner of the site and retains water from drainage areas DEV-7, DEV-8 and discharge from Pond E, through three 36 inch culverts, which retains water from drainage area DEV-1. The ponds are shown on Drawing P3-6 - Final Drainage Conditions. Calculations for the pond capacities are provided in Appendix 3B, Attachment 1 – Stormwater Calculations. Results of modeling the culverts from the existing pond are provided in Appendix 3B, Attachment 3 – Culvert Calculations.

Developed drainage patterns do not alter the pre-developed and existing conditions in such a way that hinders off-site areas. The perimeter v-ditches and ponding areas will control all runoff generated within the site. The Landfill retains the stormwater onsite as well as accepts some off-site run-on from adjacent properties located to the north, east and south. The off-site run-on is created by visual screening berms that are located approximately 30 feet beyond the property line. All drainage calculations for the facility (both existing and future conditions) include the additional run-on from these off-site areas.

The mined pit area will act as a natural low-lying infiltration basin during interim phases of Landfill operation (applicable to Sectors A through F). The low-lying areas will be graded during Sector construction so that the drainage is away from the developed Sector, preventing run-on. In addition, as each Sector is developed, delineation berms will be placed around the current Sector to prevent runoff from the

working face and run-on from the surrounding features. Retention Ponds B and C will be developed as fill progresses and interim phases are built (Sectors F and D, respectively); Retention Ponds A and E are already constructed. The site retention basins are designed to handle stormwater during all phases of construction (and also for final closure) for any stormwater runoff that leaves the non-active Landfill footprint. The calculations provided for the site retention basins in Appendix 3B, Attachment ***6***~~7~~ are for the final closure condition (i.e., the worst case scenario in which the most runoff will be directed to the retention basins); therefore the basins are adequately sized for all phases of Landfill construction. The site drainage collection, conveyance, and detention structures are designed to operate during all phases of Landfill construction so that the existing drainage patterns will not be adversely altered in accordance with 30 TAC §330.305(a). Existing and final stormwater calculations are provided in Appendix 3B, Attachment ***6***~~7~~ – Drainage Calculations. Interim structures include delineation (run-on, runoff) berms as identified on Drawing P3-29, Detail 4. Non-erodible velocities and soil loss calculations during all phases of Landfill construction are summarized in Appendix 3B (calculations are provided in Appendix 3B, Attachment ***6***~~7~~ and 5, respectively).

3.3.1.4 Erosion and Sedimentation Control Plan

The facility has been designed to prevent discharge of pollutants into waters of the State or waters of the United States, as defined by the Texas Water Code and the Federal Clean Water Act. An Erosion and Sedimentation Control Plan is provided in Appendix 3B. The Landfill supervisor is responsible for maintaining drainage structures to ensure proper working order per the Site Operating Plan maintenance requirements. The Landfill submitted a notice of intent (NOI) to comply with the TPDES Multi-Sector General Permit relating to stormwater discharge and received Permit No. TXR05L795 from the TCEQ on October 28, 2011. A copy of this permit is included in Appendix 2D – TPDES Multi-Sector General Permit.

3.3.2 Flood Control and Analysis

There is an area of the Landfill, including existing Pond A, to the northwest corner that lies in the 100-year floodplain as shown on the Flood Insurance Rate Map (FIRM) Panel No. 480214 0004 C and Appendix 3D, Drawing P3-14 - 100-Year Floodplain Map. The zone designation for the floodplain is A1, which is an area of 100-year flood with already determined base flood elevations (BFE's) and flood hazard factors. The BFE's were converted from NGVD29 Datum to the City of El Paso Datum with a factor provided by Land-Mark Professional Surveying Incorporated. As shown on Drawing P3-8, the BFE's are below the site berms located around the site, and therefore the 100-year flood will be diverted around the Landfill site to the north and will not affect stormwater elevations within Pond A nor will the BFE's affect Landfill operations. The FIRM map is provided in Appendix 3D, Drawing P3-13.

Pond A was sized as described above with a storage capacity of 19.77 ac-ft. The 100-year 24-hour storm event contributes 17.67 ac-ft of runoff volume (including 25% emergency capacity and silt volume of 0.012 ac-ft/yr). Note from the high-water elevation provided on the cross sections, at least three feet of freeboard is provided in

accordance with 30 TAC §330.307(b)(1). Pond A was sized to contain the volume of runoff plus a 25% emergency capacity and silt accumulations thus minimizing the impact to the BFEs for the area. The floodplain does not come into contact with the Landfill operational areas as described above.

3.3.3 Conclusion

The facility has been designed to comply with 30 TAC §330.301 through §330.307.

This report has been prepared consistent with the requirements of 30 TAC §330.301-330.307. Included in this report are pre-developed, existing, and developed drainage area maps along with erosion control measures and drainage control features. Also provided are hydrologic calculations for pre-developed, existing and developed Landfill conditions. These calculations demonstrate that there is no significant alteration in drainage patterns due to the development of the Landfill. During all phases of construction, the Facility will be constructed, maintained and operated to ensure that run-on and runoff during the 25-year storm event is controlled within the site.

3.3.1 Drainage Analysis

3.3.1.1 Concepts and Methods

The hydrologic and hydraulic methods employed in this report are consistent with TCEQ regulations. The criterion used is located in the Texas Department of Transportation Bridge Division Hydraulic Design Manual (DOT Drainage Manual). The hydrologic and hydraulic analyses were performed using the Rational Method and Manning's Equation respectively. The Rational Method is based on the maximum flow rate from a drainage area being produced by flows at a given rainfall intensity contributing to the flow at the point of discharge.

The Rational Method equation (in English Units) is as follows:

$Q = CIA$

Where:

Q = Flow rate of Discharge, in cubic feet per second (cfs)

C = Runoff Coefficient, which is unitless

I = Rainfall Intensity, in inches per hour (in/hr)

A = Drainage Area, in acres

The Intensity (I) for a rainstorm is determined from the formula (in English units):

$I = b/[(T_c+d)^e]$

Where:

I = Rainfall Intensity, in inches per hour

T_c = Time of Concentration, in minutes ***(Calculated using the Watershed Lag Method)***

e,b,d = Coefficients for specific frequencies, unitless

The runoff coefficient, C, is based on the topography, land cover, and land development of the contributing drainage area. Values of C from the DOT Drainage Manual are shown in Appendix 3B, Attachment 1 – Stormwater Calculations.

The rainfall intensity, I, is based on the time of concentration, T_c, in minutes. This is the time it takes the runoff to flow from the furthest point in the drainage area to the point of discharge. ~~A minimum T_c value of 10 minutes was assumed for any areas with a T_c less than 10 minutes.~~

The coefficients used for El Paso County, as obtained from the DOT Drainage Manual are shown in Appendix 3B, Attachment 1 – Stormwater Calculations.

The 24-hr, 25-yr storm event was used for the design of conveyance facilities and the 24-hr, 100-yr storm event was used for the design of ponding facilities and to check overtopping of conveyance facilities.

The volume of runoff for each drainage sub-basin was found using the NRCS Runoff Curve Number Method as discussed in the DOT Drainage Manual.

The NRCS method is expressed by the following equation (in English units):

$S = (1000/CN)-10$

Where:

S = Potential Maximum Retention (inches)

CN = Curve Number

Runoff Depth is determined from the formula (in English units):

$R = [(P-0.2S)^2]/[P+0.8S]$

Where:

R = Runoff Depth (inches)

P = Precipitation (inches)

A curve number of 68 was used for existing conditions, representing range land conditions. The closed Landfill with the rock armoring was given a conservative curve number of 73 for final developed conditions. The precipitation for the design events as discussed in the DOT drainage manual can be seen Appendix 3B, Attachment 1 – Stormwater Calculations.

3.3.1.2 Existing Conditions

The McCombs Landfill is an existing municipal solid waste disposal facility located in Section 6, Block 80, Township 1, within the city limits of El Paso, at the intersection of McCombs Road and FM 2529 (Stan Roberts Sr. Road). The site covers ***347*** ~~327~~ acres and the surrounding areas are largely undeveloped. Located west of McCombs Road is the Public Service Board - El Paso Water Utilities' Sludge Monofill.

The soils in the Landfill area are predominantly Turney-Berino Association, moderately deep over soft caliche, in the Hueco Bolson. The soils are characterized as moderately permeable, having high water-holding capacity, and having a slow runoff rate. Caliche covers the entire Bolson surface and ranges in thicknesses of immeasurable to 8 feet thick.

Pre-Developed drainage patterns and flow rates are shown on Drawing P3-3 – Pre-developed Drainage Conditions, in Appendix 3C. This drawing and drainage discharge values are from the permit dated April 2002, by Moreno Cardenas and remain the same in the Permit Modification dated April 2009 by Parkhill, Smith and Cooper, Inc. (PSC). The existing drainage patterns and flow rates are shown on Drawing P3-4 - Existing Drainage Conditions, in Appendix 3C. ***It should be noted that the existing drainage patterns have been updated to include the 19.4 acre site entrance facilities drainage area.***

Stormwater runoff is collected in a v-ditch around the perimeter of the existing Landfill units and is directed into one of the site stormwater ponds. Runoff generated to the north and east of the existing Landfill is captured in the mined pit area. Some of the runoff in the northwest corner continues to the site of existing Retention Pond A. Runoff generated to the west and south of the existing Landfill area is conveyed into existing Retention Pond D (located west of the existing fee house) and existing Retention Pond E (located in the southeastern corner of the developed Landfill area). ***Stormwater from the 19.4 acre site entrance facilities area (existing conditions) generally flows to natural low lying areas and infiltrates.***

Intermediate and long term erosion stability of this site will be dependent upon the implementation of both structural and non-structural best management practices (BMPs) which are also discussed in Appendix 3B – Surface Water Drainage Analysis.

3.3.1.3 Developed Conditions

The Final Drainage Conditions plan, provided in Appendix 3C, Drawing P3-6 shows the final developed conditions. The final contours include four ponds to break up drainage areas (the existing Retention Ponds A and E, and Ponds B and C), and in effect reduce sheet flow and minimize erosion. Existing Pond D is no longer needed as that area is filled to grade and flow is conveyed in a v-ditch to Pond E. ***Also, the final drainage conditions plan for the site entrance facilities area is provided as Drawing C-13 in Appendix 3E. Stormwater from the site entrance facilities area will be contained in one of six onsite detention areas (labeled as DA-1 through DA-6). All runoff from the site will be contained in onsite retention basins.***

A total of eight drainage sub-areas are included in the developed drainage conditions plan as shown on Drawing P3-6 - Final Drainage Conditions. Peak flow rates were calculated for each sub-area and are shown on a table within the drawing. Calculations for peak flow rates are included in Appendix 3B, Attachment 1 – Stormwater Calculations.

Stormwater runoff down the side slopes will be captured by a v-ditch, and directed to one of the four ponds. The perimeter drainage system of v-ditches is designed to convey the 25-yr storm event for each drainage basin. All ditches have also been

checked to ensure no overtopping occurs in the 100-yr storm event. Calculations for the perimeter ditch designs are provided in Appendix 3B, Attachment 2 – Ditch Calculations. The earthen v-ditches range in depth from 1.71 to 2.26 feet in depth with 3H:1V side slopes which includes at least 25% depth of freeboard. Velocities in the ditches range from 3.42 to 6.74 feet per second, as shown in Appendix 3B, Attachment 2 – Ditch Calculations. The ditches with velocities exceeding 4.0 feet per second will require erosion protection, according to maximum non-erodible velocities as published in the USDA-SCS Engineering Field Manual, as outlined in a table on the Final Drainage Conditions drawing (Drawing P3-6).

Culverts will be required to convey water from the existing stormwater Retention Pond E to Pond C, as shown on the Final Drainage Conditions drawing. The culverts were sized by Moreno Cardenas using the Heasted Methods Flowmaster program and are provided in Appendix 3B, Attachment 3. The final drainage conditions of the updated closure plan have been evaluated to ensure the culverts sized previously are adequate. The culverts can be seen on the Final Drainage Conditions drawing and the details as provided previously by Moreno Cardenas are provided on Drawings P3-9 and P3-10 in Appendix 3C.

There are two ***future*** ~~proposed~~ retention ponds (B and C) and two existing retention ponds (A and E) for the McCombs Landfill final conditions. The ponds are designed to hold the runoff from the 100-yr storm event, 25% emergency capacity, and silt volume (0.012 ac-ft/acre) generated from the drainage area. Pond A is located in the northwest corner of the site within the 100-year floodplain and retains water from drainage areas ***DEV-2*** ~~DA-2~~, ***DEV-3*** ~~DA-3~~ and ***DEV-4*** ~~DA-4~~. See Section 3.3.2 for a discussion of the 100-Year Floodplain area. This area is not regulated under the Section 404 provisions of the Clean Water Act and the Department of the Army permit is not required. A letter from the Department of the Army, date July 2002, is provided in Appendix 3B, Attachment 4. Pond B is located in the northeast corner of the site and retains water from drainage areas ***DEV-5*** ~~DA-5~~ and ***DEV-6*** ~~DA-6~~, which includes some minimal offsite run-on storm water from just outside the east property boundary. Pond C is located in the southeast corner of the site and retains water from drainage areas ***DEV-7*** ~~DA-7~~, ***DEV-8*** ~~DA-8~~ and discharge from Pond E, through three 36 inch culverts, which retains water from drainage area ***DEV-1*** ~~DA-1~~. The ponds are shown on Drawing P3-6 - Final Drainage Conditions. Calculations for the pond capacities are provided in Appendix 3B, Attachment 1 – Stormwater Calculations. Results of modeling the culverts from the existing pond are provided in Appendix 3B, Attachment 3 – Culvert Calculations.

Developed drainage patterns do not alter the pre-developed and existing conditions in such a way that hinders off-site areas. The ~~proposed~~ perimeter v-ditches and ~~proposed~~ ponding areas will control all runoff generated within the site. The Landfill retains the stormwater onsite as well as accepts some off-site run-on from adjacent properties located to the north, east and south. The off-site run-on is created by visual screening berms that are located approximately 30 feet beyond the property line. All drainage calculations for the facility (both existing and future conditions) include the additional run-on from these off-site areas.

The mined pit area will act as a ***natural low-lying infiltration*** ~~sedimentation~~ basin during interim phases of Landfill operation ***(applicable to Sectors A through F)***. ***The low-lying areas will be graded during Sector construction so that the drainage is away from the developed Sector, preventing run-on. In addition, as*** ~~As~~ each Sector is developed, delineation berms will be placed around the current Sector to prevent runoff from the working face and run-on from the surrounding features. ***Retention Ponds B and C*** ~~Stormwater basins~~ will be developed as fill progresses and interim phases are built ***(Sectors F and D, respectively); Retention Ponds A and E are already constructed***. ***The site retention basins are designed to handle stormwater during all phases of construction (and also for final closure) for any stormwater runoff that leaves the non-active Landfill footprint. The calculations provided for the site retention basins in Appendix 3B, Attachment 7 are for the final closure condition (i.e., the worst case scenario in which the most runoff will be directed to the retention basins); therefore the basins are adequately sized for all phases of Landfill construction.*** The site drainage collection, conveyance, and detention structures are designed to operate during all phases of Landfill construction so that the existing drainage patterns will not be adversely altered in accordance with 30 TAC §330.305(a). ***Existing and final s***tormwater calculations are provided in Appendix 3B, Attachment 7 – Drainage Calculations. ***Interim structures include delineation (run-on, runoff) berms as identified on Drawing P3-29, Detail 4. Non-erodible velocities and soil loss calculations during all phases of Landfill construction are summarized in Appendix 3B (calculations are provided in Appendix 3B, Attachment 7 and 5, respectively).***

3.3.1.4 Erosion and Sedimentation Control Plan

The facility has been designed to prevent discharge of pollutants into waters of the State or waters of the United States, as defined by the Texas Water Code and the Federal Clean Water Act. An Erosion and Sedimentation Control Plan is provided in Appendix 3B. The Landfill supervisor is responsible for maintaining drainage structures to ensure proper working order per the Site Operating Plan maintenance requirements. The Landfill submitted a notice of intent (NOI) to comply with the TPDES Multi-Sector General Permit relating to stormwater discharge and received Permit No. TXR05L795 from the TCEQ on October 28, 2011. A copy of this permit is included in Appendix 2D – TPDES Multi-Sector General Permit.

3.3.2 Flood Control and Analysis

There is an area of the Landfill, including existing Pond A, to the northwest corner that lies in the 100-year floodplain as shown on the Flood Insurance Rate Map (FIRM) Panel No. 480214 0004 C and Appendix 3D, Drawing P3-14 - 100-Year Floodplain Map. The zone designation for the floodplain is A1, which is an area of 100-year flood with already determined base flood elevations (BFE's) and flood hazard factors. The BFE's were converted from NGVD29 Datum to the City of El Paso Datum with a factor provided by Land-Mark Professional Surveying Incorporated. As shown on Drawing P3-8, the BFE's are below the site berms located around the site, and therefore the 100-year flood will be diverted around the Landfill site to the north and

will not affect stormwater elevations within Pond A nor will the BFE's affect Landfill operations. The FIRM map is provided in Appendix 3D, Drawing P3-13.

Pond A was sized as described above with a storage capacity of 19.77 ac-ft. The 100-year 24-hour storm event contributes 17.67 ac-ft of runoff volume (including 25% emergency capacity and silt volume of 0.012 ac-ft/yr). Note from the high-water elevation provided on the cross sections, at least three feet of freeboard is provided in accordance with 30 TAC §330.307(b)(1). Pond A was sized to contain the volume of runoff plus a 25% emergency capacity and silt accumulations thus minimizing the impact to the BFEs for the area. The floodplain does not come into contact with the ~~proposed~~ Landfill operational areas as described above.

3.3.3 Conclusion

The facility has been designed to comply with 30 TAC §330.301 through §330.307.

This report has been prepared consistent with the requirements of 30 TAC §330.301-330.307. Included in this report are pre-developed, existing, and developed drainage area maps along with erosion control measures and drainage control features. Also provided are hydrologic calculations for pre-developed, existing and developed landfill conditions. These calculations demonstrate that there is no significant alteration in drainage patterns due to the development of the landfill. ***During all phases of construction, the Facility will be constructed, maintained and operated to ensure that run-on and runoff during the 25-year storm event is controlled within the site.***

3.3.1 Drainage Analysis

3.3.1.1 Concepts and Methods

The hydrologic and hydraulic methods employed in this report are consistent with TCEQ regulations. The criterion used is located in the Texas Department of Transportation Bridge Division Hydraulic Design Manual (DOT Drainage Manual). The hydrologic and hydraulic analyses were performed using the Rational Method and Manning's Equation respectively. The Rational Method is based on the maximum flow rate from a drainage area being produced by flows at a given rainfall intensity contributing to the flow at the point of discharge.

The Rational Method equation (in English Units) is as follows:

$Q = CIA$

Where:

Q = Flowrate of Discharge, in cubic feet per second (cfs)

C = Runoff Coefficient, which is unitless

I = Rainfall Intensity, in inches per hour (in/hr)

A = Drainage Area, in acres

The Intensity (I) for a rainstorm is determined from the formula (in English units):

$I = b/[(t_c+d)^e]$

Where:

I = Rainfall Intensity, in inches per hour

t_c = Time of Concentration, in minutes

e,b,d = Coefficients for specific frequencies, unitless

The runoff coefficient, C, is based on the topography, land cover, and land development of the contributing drainage area. Values of C from the DOT Drainage Manual are shown in Appendix 3B, Attachment 1 – Stormwater Calculations.

The rainfall intensity, I, is based on the time of concentration, T_c, in minutes. This is the time it takes the runoff to flow from the furthest point in the drainage area to the point of discharge. A minimum T_c value of 10 minutes was assumed for any areas with a T_c less than 10 minutes.

The coefficients used for El Paso County, as obtained from the DOT Drainage Manual are shown in Appendix 3B, Attachment 1 – Stormwater Calculations.

The 24-hr, 25-yr storm event was used for the design of conveyance facilities and the 24-hr, 100-yr storm event was used for the design of ponding facilities and to check overtopping of conveyance facilities.

The volume of runoff for each drainage sub-basin was found using the NRCS Runoff Curve Number Method as discussed in the DOT Drainage Manual.

The NRCS method is expressed by the following equation (in English units):

$S = (1000/CN)-10$

Where:

S = Potential Maximum Retention (inches)

CN = Curve Number

Runoff Depth is determined from the formula (in English units):

$R = [(P-0.2S)^2]/[P+0.8S]$

Where:

R = Runoff Depth (inches)

P = Precipitation (inches)

A curve number of 68 was used for existing conditions, representing range land conditions. The closed landfill with the rock armoring was given a conservative curve number of 73 for final developed conditions. The precipitation for the design events as discussed in the DOT drainage manual can be seen Appendix 3B, Attachment 1 – Stormwater Calculations.

3.3.1.2 Existing Conditions

The McCombs Landfill is an existing municipal solid waste disposal facility located in Section 6, Block 80, Township 1, within the city limits of El Paso, at the intersection of McCombs Road and FM 2529 (Stan Roberts Sr. Road). The site covers 327 acres and the surrounding areas are largely undeveloped. Located west of McCombs Road is the Public Service Board - El Paso Water Utilities' Sludge Monofill.

The soils in the landfill area are predominantly Turney-Berino Association, moderately deep over soft caliche, in the Hueco Bolson. The soils are characterized as

moderately permeable, having high water-holding capacity, and having a slow runoff rate. Caliche covers the entire Bolson surface and ranges in thicknesses of immeasurable to 8 feet thick.

Pre-Developed drainage patterns and flowrates are shown on Drawing P3-3 – Pre-developed Drainage Conditions, in Appendix 3C. This drawing and drainage discharge values are from the permit dated April 2002, by Moreno Cardenas and remain the same in the Permit Modification dated April 2009 by Parkhill, Smith and Cooper, Inc. (PSC). The existing drainage patterns and flowrates are shown on Drawing P3-4 - Existing Drainage Conditions, in Appendix 3C.

Stormwater runoff is collected in a v-ditch around the perimeter of the existing landfill units and is directed into one of the site stormwater ponds. Runoff generated to the north and east of the existing landfill is captured in the mined pit area. Some of the runoff in the northwest corner continues to the site of existing Retention Pond A. Runoff generated to the west and south of the existing landfill area is conveyed into existing Retention Pond D (located west of the existing fee house) and existing Retention Pond E (located in the southeastern corner of the developed landfill area).

Intermediate and long term erosion stability of this site will be dependent upon the implementation of both structural and non-structural best management practices (BMPs) which are also discussed in Appendix 3B – Surface Water Drainage Analysis.

3.3.1.3 Developed Conditions

The Final Drainage Conditions plan, provided in Appendix 3C, Drawing P3-6 shows the final developed conditions. The final contours include four ponds to break up drainage areas (the existing Retention Ponds A and E, and Ponds B and C), and in effect reduce sheet flow and minimize erosion. Existing Pond D is no longer needed as that area is filled to grade and flow is conveyed in a v-ditch to Pond E.

A total of eight drainage sub-areas are included in the developed drainage conditions plan as shown on Drawing P3-6 - Final Drainage Conditions. Peak flow rates were calculated for each sub-area and are shown on a table within the drawing. Calculations for peak flow rates are included in Appendix 3B, Attachment 1 – Stormwater Calculations.

Stormwater runoff down the side slopes will be captured by a v-ditch, and directed to one of the four ponds. The perimeter drainage system of v-ditches is designed to convey the 25-yr storm event for each drainage basin. All ditches have also been checked to ensure no overtopping occurs in the 100-yr storm event. Calculations for the perimeter ditch designs are provided in Appendix 3B, Attachment 2 – Ditch Calculations. The earthen v-ditches range in depth from 1.71 to 2.26 feet in depth with 3H:1V side slopes which includes at least 25% depth of freeboard. Velocities in the ditches range from 3.42 to 6.74 feet per second, as shown in Appendix 3B, Attachment 2 – Ditch Calculations. The ditches with velocities exceeding 4.0 feet per second will require erosion protection, according to maximum non-erodible velocities as published in the USDA-SCS Engineering Field Manual, as outlined in a table on the Final Drainage Conditions drawing ***(Drawing P3-6)***.

Culverts will be required to convey water from the existing stormwater Retention Pond E to Pond C, as shown on the Final Drainage Conditions drawing. The culverts were sized by Moreno Cardenas using the Heasted Methods Flowmaster program ***and are provided in Appendix 3B, Attachment 3***~~as shown in the McCombs Landfill MSW Permit No. 729A, Permit Modification dated April 24, 2002 (Revision 1 – August 7, 2002)~~. The final drainage conditions of the updated closure plan have been evaluated to ensure the culverts sized previously are adequate. The culverts can be seen on the Final Drainage Conditions drawing and the details as provided previously by Moreno Cardenas are provided on Drawings P3-9 and P3-10 in Appendix 3C.

There are two proposed retention ponds (B and C) and two existing retention ponds (A and E) for the McCombs Landfill final conditions. The ponds are designed to hold the runoff from the 100-yr storm event, 25% emergency capacity, and silt volume (0.012 ac-ft/acre) generated from the drainage area. Pond A is located in the northwest corner of the site within the 100-year floodplain and retains water from drainage areas DA-2, DA-3 and DA-4. See Section 3.3.2 for a discussion of the 100-Year Floodplain area. This area is not regulated under the Section 404 provisions of the Clean Water Act and the Department of the Army permit is not required. A letter from the Department of the Army, date July 2002, is provided in Appendix 3B, Attachment 4. Pond B is located in the northeast corner of the site and retains water from drainage areas DA-5 and DA-6, which includes some minimal offsite run-on storm water from just outside the east property boundary. Pond C is located in the southeast corner of the site and retains water from drainage areas DA-7, DA-8 and discharge from Pond E, through three 36 inch culverts, which retains water from drainage area DA-1. The ponds are shown on Drawing P3-6 - Final Drainage Conditions. Calculations for the pond capacities are provided in Appendix 3B, Attachment 1 – Stormwater Calculations. Results of modeling the culverts from the existing pond are provided in Appendix 3B, Attachment 3 – Culvert Calculations.

Developed drainage patterns do not alter the pre-developed and existing conditions in such a way that hinders off-site areas. The proposed perimeter v-ditches and proposed ponding areas will control all runoff generated within the site. The Landfill retains the stormwater onsite as well as accepts some off-site run-on from ~~the east~~ ***adjacent properties located to the north, east and south***. ***The off-site run-on is created by visual screening berms that are located approximately 30 feet beyond the property line. All drainage calculations for the facility (both existing and future conditions) include the additional run-on from these off-site areas.***

The mined pit area will act as a sedimentation basin during interim phases of landfill operation. As each Sector is developed, delineation berms will be placed around the current Sector to prevent runoff from the working face and run-on from the surrounding features. Stormwater basins will be developed as fill progresses and interim phases are built. The site drainage collection, conveyance, and detention structures are designed to operate during all phases of landfill construction so that the existing drainage patterns will not be adversely altered in accordance with 30 TAC §330.305(a). Stormwater calculations are provided in Appendix 3B, Attachment 7 – Drainage Calculations.

3.3.1.4 Erosion and Sedimentation Control Plan

The facility has been designed to prevent discharge of pollutants into waters of the State or waters of the United States, as defined by the Texas Water Code and the Federal Clean Water Act. An Erosion and Sedimentation Control Plan is provided in Appendix 3B. The landfill supervisor is responsible for maintaining drainage structures to ensure proper working order per the Site Operating Plan maintenance requirements. The Landfill submitted a notice of intent (NOI) to comply with the ~~NPDES~~ ***TPDES Multi-Sector*** General Permit relating to stormwater discharge and received Permit No. ~~TXR05E214~~ ***TXR05L795*** from the ~~United States Environmental Protection Agency (U.S. EPA) in June of 1998~~ ***TCEQ on October 28, 2011***. A copy of this permit is included in Appendix 2D – ***TPDES Multi-Sector General Permit*** ~~NPDES Certification~~.

3.3.2 Flood Control and Analysis

There is an area of the landfill, including ***existing*** ~~proposed~~ Pond A, to the northwest corner that lies in the 100-year floodplain as shown on the Flood Insurance Rate Map (FIRM) Panel No. 480214 0004 C and Appendix 3D, Drawing P3-14 - 100-Year Floodplain Map. The zone designation for the floodplain is A1, which is an area of 100-year flood with already determined base flood elevations ***(BFE's)*** and flood hazard factors. ~~The proposed landfill development base elevations are above the base flood elevations (BFE's) and is in accordance with TAC §330.56 (f)(4)(B)(iii)~~. The BFE's were converted from NGVD29 Datum to the City of El Paso Datum with a factor provided by Land-Mark Professional Surveying Incorporated ~~in the McCombs Landfill MSW Permit No. 729A, Permit Modification dated April 24, 2002 (Revision 1 – August 7, 2002), completed by Moreno Cardenas~~. ***As shown on Drawing P3-8, the BFE's are below the site berms located around the site, and therefore the 100-year flood will be diverted around the landfill site to the north and will not affect stormwater elevations within Pond A nor will the BFE's affect landfill operations.*** The FIRM map is provided in Appendix 3D, Drawing P3-13.

Pond A was sized as described above with a storage capacity of 19.77 ac-ft. The 100-year ***24-hour*** storm event contributes 17.67 ac-ft of runoff volume (including 25% emergency capacity and silt volume of 0.012 ac-ft/yr). ***Note from the high-water elevation provided on the cross sections, at least three feet of freeboard is provided in accordance with 30 TAC §330.307(b)(1). Pond A was sized to contain the volume of runoff plus a 25% emergency capacity and silt accumulations thus minimizing the impact to the BFEs for the area.*** ~~The storage capacity from construction of Pond A does not impact the existing BFE's and per TAC §330.56(B)(iii).~~ ~~the~~ ***The*** floodplain does not come into contact with the proposed landfill operational areas ***as described above***.

3.3.3 Conclusion

The facility has been designed to comply with 30 TAC §330.301 through §330.307.

This waste management unit design plan for the Landfill addresses all weather operation, identifies the method used for landfilling, identifies the deepest excavation, estimates the waste deposition rate, projects site life, provides cross sections of the Landfill, provides a liner quality control plan, and provides a final cover quality control plan.

3.4.1 Landfill Unit Design

3.4.1.1 Provisions for All-Weather Operation

30 TAC §330.63(d)(4)(A)

Precautions will be taken to ensure all roads are passable during all weather conditions. New all-weather roads will be constructed as fill progresses in each area of the Landfill. The roads will consist of a compacted layer on the road surface to minimize mud tracking and allow access during all weather conditions. The main access road to the site will be constructed with a top layer of flexible pavement.

3.4.1.2 Proposed Landfill Method

30 TAC §330.63(d)(4)(B)

The McCombs Landfill has broken up development into eleven sectors. These sectors are identified as A through K. Drawings depicting this layout, existing site conditions, final fill height, drainage structures, and entrance facilities are provided in Appendix 3E - Site Layout Plans. Area filling will take place in each sector before moving onto the next. The settlement rate will be affected by the method of landfilling, the amount of moisture in the refuse, and by the amount of compaction received. Poor compaction and high lifts would result in more settlement. Decomposition is anticipated to be slow due to the low amount of precipitation received on average in the area. An in-place density of 1,200 pounds per cubic yard (lb/cy) or greater will reduce the amount of settlement.

Excavation side slopes and final side slopes will be no steeper than 3H:1V, and the final top slope will be approximately 7%. Placement of final cover will generally follow the same sequence of development, sector A through K. Closure of each sector will be in accordance with the closure plan provided in Section 3.8 – Final Closure Plan.

3.4.1.3 Elevation of Deepest Excavation

30 TAC §330.63(d)(4)(C)

The deepest elevation of excavation will be approximately 4017 feet above mean sea level (msl) in the leachate collection sumps. The minimum waste placement elevation will be approximately 4024 above msl (minimum base elevation of 4022 plus two-feet for protective sand layer). The maximum elevation of final cover will be 4305 feet above msl. The maximum elevation for disposed waste will be 4301.7 feet above msl (for the alternative cover profile). All elevations listed are in City of El Paso vertical datum.

3.4.1.4 Estimated Waste Deposition Rate and Site Life

30 TAC §330.63(d)(4)(D)

The estimated rate of disposal was calculated assuming an annual population increase of 2% in growth, and assuming a disposal rate of 497,309 tons per year (in 2014 tonnage) until Clint Landfill closes in 2030. 3,000 tons per year are assumed from 2011 through 2013. After Clint Landfill closes, McCombs Landfill will receive all of the waste that would have previously been received at the Clint Landfill, therefore the disposal rate at McCombs will raise from 45% of the county waste allocation to 100%. The 1990 base population for central, northeastern and northwestern areas of El Paso (areas where solid waste is planned to go to the McCombs Landfill) was used for the growth rate estimation. The population for the above mentioned areas in 1990 was 322,842 people. Using the rate above, and an airspace utilization factor of 1200 lb/cy, the estimated life of the Landfill is to 2059.

The total remaining Landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including waste and daily, intermediate and final cover), which provides capacity through 2014, based on table 3.4H-1 in Appendix 3H - Site Life Projections. The total remaining Landfill volume available for waste disposal including the remainder of Sector A and all subsequent planned sectors (B through K) is ***62,853,182***~~62,532,764~~ CY, which provides a site life until 2059. Calculations and assumptions for this waste volume and site life are included in Appendix 3H - Site Life Projections.

3.4.1.5 Landfill Cross-Sections

30 TAC §330.63(d)(4)(E)and(F)

Cross sections of the Landfill are located in Appendix 3F. These sections show the existing ground elevations; anticipated base elevation of excavation; bottom, side slope and vertical fill elevations; permitted fill elevations; existing groundwater monitoring wells; and the liner and cover system elevations. Top of waste elevation; perimeter or toe berm details; gas vents or wells; and groundwater elevations are included by reference to other portions of the permit document. The sections shown are representative of the entire site.

3.4.1.6 Liner Quality Control Plan

30 TAC §330.63(d)(4)(G)

A quality control plan for the base composite liner system in accordance with §330.339 is provided in Appendix 3J - Liner Quality Control Plan. The components of the current ***alternative*** ~~prescriptive composite~~ liner system ***(Scenario 1)*** are listed from top to bottom in Table 3.4-1 and components of the ***proposed*** alternative ~~composite~~ liner system ***(Scenario 2)*** are listed from top to bottom in Table 3.4-2. ~~For ease of distinguishing the difference between the two alternative liners for the facility, the previously permitted alternative liner will be referenced as the "prescriptive liner" throughout this permit and the new alternative liner will be referred to as the "alternative liner".~~ It should be noted that the modeling results for both ***Scenario 1*** ~~the previously approved prescriptive liner~~ and ***Scenario 2*** ~~the new alternative liner~~ are provided in Appendix 3J. The components for the expansion piggyback ***liner (Scenario 3)*** onto the existing ***unlined*** MSW area are listed from top to bottom in Table 3.4-3. The expansion piggyback liner will be placed in Sectors H, I, and J (approximately ***64*** ~~78~~ acres***, see Drawing P3-28B in Appendix 3G, Attachment 4***). Detail drawings of the liner system are located in Appendix 3G - Construction Design Details, Drawing P3-28 – Landfill Base Plan

Table 3.4-1
Components of the *Scenario 1* ~~Prescriptive Composite~~Liner System in Descending Order

Liner System Component	Description	Thickness
Protective Cover	Sand with coefficient of permeability greater than or equal to $1x10^{-3}$ cm/sec	24 inches
Geomembrane Liner	Textured HDPE Geomembrane *(permeability less than or equal to $2x10^{-13}$ cm/sec)*	60 mil
Compacted Soil ~~Composite~~ Liner	Compacted Caliche with a coefficient of permeability less than or equal to $1x10^{-7}$ cm/sec	6 inches
Compacted Soil Liner	Compacted Native Soil or Interim Cover Soil	6 inches

Table 3.4-2
Components of the *Scenario 2* ~~Alternative Composite~~ Liner System in Descending Order

Liner System Component	Description	Thickness
Protective Cover	Sand with coefficient of permeability greater than or equal to $1x10^{-3}$ cm/sec	24 inches
Geomembrane Liner	Textured HDPE Geomembrane *(permeability less than or equal to $2x10^{-13}$ cm/sec)*	60 mil
Geosynthetic Clay ~~Composite~~ Liner	Geosynthetic Clay Liner (GCL) with a coefficient of permeability less than or equal to $5x10^{-9}$ cm/sec	~~NA~~ *Approx. 0.24 inches*
Compacted Soil Liner	Compacted Native Soil or Interim Cover Soil	6 inches

Table 3.4-3
Components of the *Scenario 3* ~~Composite Liner System for the Expansion Piggyback~~ Liner *System* in Descending Order

Liner System Component	Description	Thickness
Protective Cover	Sand with coefficient of permeability greater than or equal to $1x10^{-3}$ cm/sec	24 inches
Geomembrane Liner	Textured HDPE Geomembrane *(permeability less than or equal to $2x10^{-13}$ cm/sec)*	60 mil
Geosynthetic Clay ~~Composite~~ Liner	Geosynthetic Clay Liner (GCL) with a coefficient of permeability less than or equal to $5x10^{-9}$ cm/sec	~~NA~~ *Approx. 0.24 inches*
Geogrid Stabilization Layer	Uniaxial Layers Placed Perpendicular to One Another	2 layers
Interim Cover Soil	Sand with coefficient of permeability greater than or equal to $1x10^{-3}$ cm/sec	6 inches
Compacted Buffer Soil	On Site Soil	36 inches

3.4.1.7 Final Cover Quality Control Plan

30 TAC §330.457

A quality control plan for the final cover system is included in Appendix 3O. Detail drawings of the final cover system are provided in Appendix 3G, Drawing P3-33 - Final Cover Plan, and Drawing P3-34 – Final Cover Details. The components of the prescriptive final cover system for lined areas of the Landfill are listed from top to bottom in Table 3.4-4 below. The components of the prescriptive final cover system for unlined areas of the Landfill are listed from top to bottom in Table 3.4-5. The

components of the alternative final cover system (for both lined and unlined Landfill areas) are listed from top to bottom in Table 3.4-6.

Table 3.4-4
Components of the Prescriptive Final Cover System in Descending Order (Lined Landfill)

Cover System Component	Description	Thickness
Topsoil Layer	Native Topsoil or Rock Armoring	6 inches topsoil or 4 inches rock
Erosion Layer	Earthen Material	12 inches
Flexible Membrane Cover	Textured LLDPE or VLPE Liner	40 mil
Infiltration Layer	Sand with a permeability less than or equal to $1x10^{-5}$ cm/sec	18 inches
Intermediate/Daily Cover	Native Soil	12 inches

Table 3.4-5
Components of the Prescriptive Final Cover System in Descending Order (Unlined Landfill)

Cover System Component	Description	Thickness
Topsoil Layer	Native Topsoil or Rock Armoring	6 inches topsoil or 4 inches rock
Erosion Layer	Soil with a coefficient of permeability less than or equal to $1x10^{-5}$ cm/sec	18 inches
Intermediate/Daily Cover	Native Soil	12 inches

Table 3.4-6
Components of the Alternative Final Cover System in Descending Order

Cover System Component	Description	Thickness
Top Layer	Rock Armoring	4 inches
Erosion Layer	Material placed at 90% compaction	18 inches
Support Layer	Material placed at 80% compaction	6 inches
Intermediate/Daily Cover	Native Soil	12 inches

3.4.2 Storage and Transfer Units

3.4.2.1 Citizen's Collection Area

All residents and some commercial haulers will be directed to the PDA to dispose of wastes in roll-off containers. Trained Landfill personnel will be positioned at the public drop-off area and working face to visually screen for prohibited items. Customers disposing of bulky items and white goods will also be directed towards the PDA for unloading. Acceptable bulky items and white goods include automobiles,

metal tanks, large metal pieces, and household appliances that have had all chlorinated fluorocarbons (CFCs) removed in accordance with 40 CFR §82.156(f). These items will be recycled by a permitted salvage company under contract with the City.

This ***waste management*** ~~landfill~~ unit design plan for the Landfill addresses all weather operation, identifies the method used for landfilling, identifies the deepest excavation, estimates the waste deposition rate, projects site life, provides cross sections of the Landfill, provides a liner quality control plan, and provides a final cover quality control plan.

3.4.1 Landfill Unit Design

3.4.1.1 Provisions for All-Weather Operation

30 TAC §330.63(d)(4)(A)

Precautions will be taken to ensure all roads are passable during all weather conditions. New all-weather roads will be constructed as fill progresses in each area of the Landfill. The roads will consist of a compacted layer on the road surface to minimize mud tracking and allow access during all weather conditions. The main access road to the site will be constructed with a top layer of flexible pavement.

3.4.1.2 Proposed Landfill Method

30 TAC §330.63(d)(4)(B)

The McCombs Landfill has broken up ~~proposed~~ development into eleven ***sectors***~~sections~~. These ***sectors*** ~~sections~~ are identified as A through K. Drawings depicting this layout, existing site conditions, final fill height, drainage structures, and entrance facilities are provided in Appendix 3E - Site Layout Plans. Area filling will take place in each ***sector*** ~~section~~ before moving onto the next. The settlement rate will be affected by the method of landfilling, the amount of moisture in the refuse, and by the amount of compaction received. Poor compaction and high lifts would result in more settlement. Decomposition is anticipated to be slow due to the low amount of precipitation received on average in the area. ***An*** ~~The~~ in-place density of 1,200 ***pounds per cubic yard (***lb/cy***)*** or greater will reduce the amount of settlement.

Excavation side slopes and final side slopes will be no steeper than 3H:1V, and the final top slope will be approximately 7%. Placement of final cover will generally follow the same sequence of development, ***sector*** ~~sections~~ A through K. Closure of each ***sector*** ~~section~~ will be in accordance with the closure plan provided in Section 3.8 – Final Closure Plan.

3.4.1.3 Elevation of Deepest Excavation

30 TAC §330.63(d)(4)(C)

The deepest elevation of excavation will be approximately ***4017*** ~~4022~~ feet above mean sea level (msl) ***in the leachate collection sumps***. ***The minimum waste placement elevation will be approximately 4024 above msl (minimum base elevation of 4022 plus two-feet for protective sand layer).*** The maximum elevation of ~~disposed waste and~~ final cover will be 4305 feet above msl. ***The maximum elevation for disposed waste will be 4301.7 feet above msl (for the alternative cover profile). All elevations listed are in City of El Paso vertical datum.***

3.4.1.4 Estimated Waste Deposition Rate and Site Life

30 TAC §330.63(d)(4)(D)

The estimated rate of disposal was calculated assuming an annual population increase of 2% in growth, and assuming a disposal rate of 497,309 tons per year (in 2014 tonnage) until Clint Landfill closes in 2030. 3,000 tons per year are assumed from 2011 through 2013. After Clint Landfill closes, McCombs Landfill will receive all of the waste that would have previously been received at the Clint Landfill, therefore the disposal rate at McCombs will raise from 45% of the county waste allocation to 100%. The 1990 base population for central, northeastern and northwestern areas of El Paso (areas where solid waste is planned to go to the McCombs Landfill) was used for the growth rate estimation. The population for the above mentioned areas in 1990 was 322,842 people. Using the rate above, and an airspace utilization factor of 1200 lb/cy, the estimated life of the Landfill is to 2059.

The total remaining Landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including waste and daily, intermediate and final cover), which provides capacity through 2014, based on table 3.4H-1 in Appendix 3H - Site Life Projections. The total remaining Landfill volume available for waste disposal including the remainder of Sector A and all subsequent planned sectors (B through K) is 62,532,764 CY, which provides a site life until 2059. Calculations and assumptions for this waste volume and site life are included in Appendix 3H - Site Life Projections.

3.4.1.5 Landfill Cross-Sections

30 TAC §330.63(d)(4)(E)and(F)

Cross sections of the Landfill are located in Appendix 3F. These sections show the existing ground elevations; anticipated base elevation of excavation; bottom, side slope and vertical fill elevations; permitted fill elevations; existing groundwater monitoring wells; and the liner and cover system elevations. Top of waste elevation; perimeter or toe berm details; gas vents or wells; and groundwater elevations are included by reference to other portions of the permit document. The sections shown are representative of the entire site.

3.4.1.6 Liner Quality Control Plan

30 TAC §330.63(d)(4)(G)

A quality control plan for the base composite liner system in accordance with §330.339 is provided in Appendix 3J - Liner Quality Control Plan. The components of the prescriptive composite liner system are listed from top to bottom in Table 3.4-1 and components of the ***alternative*** ~~proposed~~ composite liner system are listed from top to bottom in Table 3.4-2. ***For ease of distinguishing the difference between the two alternative liners for the facility, the previously permitted alternative liner will be referenced as the "prescriptive liner" throughout this permit and the new alternative liner will be referred to as the "alternative liner". It should be noted that the modeling results for both the previously approved prescriptive liner and the new alternative liner are provided in Appendix 3J.*** The components for the ***expansion*** ~~proposed~~ piggyback onto the existing MSW area are listed from top to bottom in Table 3.4-3. ***The expansion piggyback liner will be placed in Sectors H, I, and J (approximately 78 acres).*** Detail drawings of the liner system are located in Appendix 3G - Construction Design Details, Drawing P3-28 – Landfill Base Plan

Table 3.4-1
Components of the Prescriptive Composite Liner System in Descending Order

Liner System Component	Description	Thickness
Protective Cover	Sand with coefficient of permeability greater than or equal to $1x10^{-3}$ cm/sec	24 inches
Geomembrane Liner	Textured HDPE Geomembrane	60 mil
Composite Liner	Compacted Caliche with a coefficient of permeability less than or equal to $1x10^{-7}$ cm/sec	6 inches

Liner System Component	Description	Thickness
Protective Cover	Sand with coefficient of permeability greater than or equal to $1x10^{-3}$ cm/sec	24 inches
Geomembrane Liner	Textured HDPE Geomembrane	60 mil
Composite Liner	Geosynthetic Clay Liner (GCL) with a coefficient of permeability less than or equal to $5x10^{-9}$ cm/sec	NA
Geogrid Stabilization Layer	Uniaxial Layers Placed Perpendicular to One Another	2 layers
Interim Cover Soil	Sand with coefficient of permeability greater than or equal to $1x10^{-3}$ cm/sec	6 inches
Compacted Buffer Soil	On Site Soil	36 inches

3.4.1.7 Final Cover Quality Control Plan

30 TAC §330.457

A quality control plan for the final cover system is included in Appendix 3O. Detail drawings of the final cover system are provided in Appendix 3G, Drawing P3-33 - Final Cover Plan, and Drawing P3-34 – Final Cover Details. The components of the prescriptive final cover system for lined areas of the Landfill are listed from top to bottom in Table 3.4-4 below. The components of the prescriptive final cover system for unlined areas of the Landfill are listed from top to bottom in Table 3.4-5. The components of the alternative final cover system (for both lined and unlined Landfill areas) are listed from top to bottom in Table 3.4-6.

Table 3.4-4
Components of the Prescriptive Final Cover System in Descending Order (Lined Landfill)

Cover System Component	Description	Thickness
Topsoil Layer	Native Topsoil or Rock Armoring	6 inches topsoil or 4 inches rock
Erosion Layer	Earthen Material	12 inches
Flexible Membrane Cover	Textured LLDPE or VLPE Liner	40 mil
Infiltration Layer	Sand with a permeability less than or equal to $1x10^{-5}$ cm/sec	18 inches
Intermediate/Daily Cover	Native Soil	12 inches

3.4.2 Storage and Transfer Units

3.4.2.1 Citizen's Collection Area

All residents and some commercial haulers will be directed to the PDA to dispose of wastes in roll-off containers. Trained Landfill personnel will be positioned at the public drop-off area and working face to visually screen for prohibited items. Customers disposing of bulky items and white goods will also be directed towards the PDA for unloading. Acceptable bulky items and white goods include automobiles, metal tanks, large metal pieces, and household appliances that have had all chlorinated fluorocarbons (CFCs) removed in accordance with 40 CFR §82.156(f). These items will be recycled by a permitted salvage company under contract with the City.

This landfill unit design plan for the Landfill addresses all weather operation, identifies the method used for landfilling, identifies the deepest excavation, estimates the waste deposition rate, projects site life, provides cross sections of the landfill, provides a liner quality control plan, and provides a final cover quality control plan.

3.4.1 Landfill Unit Design

3.4.1.1 Provisions for All-Weather Operation

30 TAC §330.63(d)(4)(A)

Precautions will be taken to ensure all roads are passable during all weather conditions. New all-weather roads will be constructed as fill progresses in each area of the Landfill. The roads will consist of a compacted layer on the road surface to minimize mud tracking and allow access during all weather conditions. The main access road to the site will be constructed with a top layer of flexible pavement.

3.4.1.2 Proposed Landfill Method

30 TAC §330.63(d)(4)(B)

The McCombs Landfill has broken up proposed development into eleven sections. These sections are identified as A through K. Drawings depicting this layout, existing site conditions, final fill height, drainage structures, and entrance facilities are provided in Appendix 3E - Site Layout Plans. Area filling will take place in each section before moving onto the next. The settlement rate will be affected by the method of landfilling, the amount of moisture in the refuse, and by the amount of compaction received. Poor compaction and high lifts would result in more settlement. Decomposition is anticipated to be slow due to the low amount of precipitation received on average in the area. The in-place density of 1,200 lb/cy or greater will reduce the amount of settlement.

Excavation side slopes and final side slopes will be no steeper than 3H:1V, and the final top slope will be approximately 7%. Placement of final cover will generally follow the same sequence of development, sections A through K. Closure of each section will be in accordance with the closure plan provided in Section 3.8 – Final Closure Plan.

3.4.1.3 Elevation of Deepest Excavation

30 TAC §330.63(d)(4)(C)

The deepest elevation of excavation will be approximately 4022 feet above mean sea level (msl). The maximum elevation of disposed waste and final cover will be 4305 feet above msl.

3.4.1.4 Estimated Waste Deposition Rate and Site Life

30 TAC §330.63(d)(4)(D)

The estimated rate of disposal was calculated assuming an annual population increase of 2% in growth, and assuming a disposal rate of 497,309 tons per year (in 2014 tonnage) until Clint Landfill closes in 2030. 3,000 tons per year are assumed from 2011 through 2013. After Clint Landfill closes, McCombs Landfill will receive all of the waste that would have previously been received at the Clint Landfill, therefore the disposal rate at McCombs will raise from 45% of the county waste allocation to 100%. The 1990 base population for central, northeastern and northwestern areas of El Paso (areas where solid waste is planned to go to the McCombs Landfill) was used for the growth rate estimation. The population for the above mentioned areas in 1990 was 322,842 people. Using the rate above, and an airspace utilization factor of 1200 lb/cy, the estimated life of the landfill is ***to 2059***~~47 years~~.

The total remaining landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including ~~both~~ waste ***and daily, intermediate*** and ***final***~~daily~~ cover), which provides capacity through 2014, based on table 3.4H-1 in Appendix 3H - Site Life Projections. The total remaining landfill volume available for waste disposal including the remainder of Sector A and all subsequent planned sectors (B through K) is 62,532,764 CY, which provides a site life ***until 2059***~~of 49 years~~. Calculations and assumptions for this waste volume and site life are included in Appendix 3H - Site Life Projections.

3.4.1.5 Landfill Cross-Sections

30 TAC §330.63(d)(4)(E)and(F)

Cross sections of the landfill are located in Appendix 3F. These sections show the existing ground elevations; anticipated base elevation of excavation; bottom, side slope and vertical fill elevations; permitted fill elevations; ***existing groundwater monitoring wells;*** and the liner and cover system elevations. ***Top of waste elevation; perimeter or toe berm details; gas vents or wells; and groundwater elevations are included by reference to other portions of the permit document.*** The sections shown are representative of the entire site.

3.4.1.6 Liner Quality Control Plan

30 TAC §330.63(d)(4)(G)

A quality control plan for the base composite liner system in accordance with §330.339 is provided in Appendix 3J - Liner Quality Control Plan. The components of the ***prescriptive composite liner system are listed from top to bottom in Table 3.4-1 and components of the proposed*** composite liner system are listed from top to bottom in Table 3.4-~~1~~***2***. The components for the proposed piggyback onto the existing MSW area are listed from top to bottom in Table 3.4-~~2~~***3***. Detail drawings of the liner system are located in Appendix 3G - Construction Design Details, Drawing P3-28 – Landfill Base Plan

Table 3.4-1

Interim Cover Soil	Sand *with coefficient of permeability greater than or equal to 1x10^{-3} cm/sec*	6 inches
Compacted Buffer Soil	On Site Soil	36 inches

3.4.1.7 Final Cover Quality Control Plan

30 TAC §330.457

A quality control plan for the final cover system ***is included in Appendix 3O*** ~~will be developed as the site is nearing final cover conditions~~. Detail drawings of the final cover system are provided in Appendix 3G, Drawing P3-33 - Final Cover Plan, and Drawing P3-34 – Final Cover Details. The components of the prescriptive final cover system for lined areas of the landfill are listed from top to bottom in Table 3.4-~~3~~***4*** below. The components of the prescriptive final cover system for unlined areas of the landfill are listed from top to bottom in Table 3.4-~~4~~***5***. The components of the alternative final cover system (for both lined and unlined landfill areas) are listed from top to bottom in Table 3.4-~~5~~***6***.

Table 3.4-~~3~~4
Components of the Prescriptive Final Cover System in Descending Order (Lined Landfill)

Cover System Component	Description	Thickness
Topsoil Layer	Native Topsoil or Rock Armoring	6 inches topsoil or 4 inches rock
Erosion Layer	*Earthen Material* ~~Soil with a coefficient of permeability less than or equal to 1x10^{-5} cm/sec~~	*12* ~~18~~ inches

3.4.2 Storage and Transfer Units

3.4.2.1 Citizen's Collection Area

All residents and some commercial haulers will be directed to the PDA to dispose of wastes in roll-off containers. Trained Landfill personnel will be positioned at the public drop-off area and working face to visually screen for prohibited items. Customers disposing of bulky items and white goods will also be directed towards the PDA for unloading. Acceptable bulky items and white goods include automobiles, metal tanks, large metal pieces, and household appliances that have had all chlorinated fluorocarbons (CFCs) removed in accordance with 40 CFR §82.156(f). These items will be recycled by a permitted salvage company under contract with the City.

The geologic data submitted to the TCEQ as part of the 2002 MPA has been reviewed and approved by George Richardson, Professional Geologist in the State of Texas. The geologic data, including the boring logs and cross sections, are located in Appendix 3K – Geology.

An updated Site Characteristics and Monitoring Plan has been developed by Parkhill, Smith and Cooper to conform with the requirements of 30 TAC §330.63(e) (Appendix 3K, Attachment 1).

The information provided within the Geology Report and supporting documents in Appendix 3K generally conforms with the requirements of 30 TAC §330.63(e). This permit ***amendment*** ~~modification~~ includes a request for a vertical expansion of the Landfill but no lateral expansion of the Landfill footprint. Prior to starting work on this permit ***amendment*** ~~modification~~ and during the subsequent permit review and comment period, TCEQ stated, since there is no lateral expansion of the Landfill no additional geologic site characterization is necessary.

Section 3.5
GEOLOGY REPORT
30 TAC §330.63(e)

The geologic data submitted to the TCEQ as part of the 2002 MPA has been reviewed and approved by George Richardson, Professional Geologist in the State of Texas~~, to meet the requirements set forth in 30 TAC §330.63(e)~~. The geologic data, including the boring logs and cross sections, are located in Appendix 3K – Geology.

The information provided within the Geology Report and supporting documents in Appendix 3K generally conforms with the requirements of 30 TAC §330.63(e). This permit modification includes a request for a vertical expansion of the landfill but no lateral expansion of the landfill footprint. Prior to starting work on this permit modification and during the subsequent permit review and comment period, TCEQ stated, since there is no lateral expansion of the landfill no additional geologic site characterization is necessary.

3.7.1 Introduction

This landfill gas (LFG) management plan (Plan) has been developed as required by 30 TAC §330.63(g) for the Landfill located in El Paso, Texas. This LFG management plan is consistent with the requirements set forth in 30 TAC §330.371 and provides a site-specific approach for completing LFG management. This Plan describes the existing and potential future LFG management system and discusses the operation and monitoring of these systems, including verification of results, notification procedures, and possible remediation activities. Landfill Gas Management Plans developed by R.W. Beck, dated April 3, 2009, VIVA Environmental, Inc, dated November 27, 2001, and AGRA Earth and Environmental Group, dated April 8, 1994, were used in the development of the following section and are included for reference as Appendix 3M, Attachment 4.

3.7.1.1 Purpose

Compliance with §330.371(a) requires landfills to implement a routine LFG monitoring program to ensure that the following conditions are met:

- Concentrations of methane gas does not exceed 1.25% by volume in facility structures (excluding gas control or recovery system components); and
- Concentrations of methane gas does not exceed 5% by volume in monitoring points, probes, or other matrices at the facility boundary.

The purpose of this plan is to provide guidelines for the management of LFG and to provide guidance if the levels of methane exceed the limits specified above. Pursuant to §330.371(c), if methane levels are exceeded, the owner or operator shall take the following steps:

- Ensure protection of human health, and notify the Executive Director, local and county officials, emergency officials, and the public of the exceedance;
- Within seven days of the detection, operating records shall be updated to reflect the concentration of methane gas levels detected and the steps that were taken to protect human health; and
- Within 60 days of exceedance, a remediation plan shall be implemented to control methane gas releases. Copies of the remediation plan shall be placed in the operating record, provided to the Executive Director, and notification to the Executive Director that the plan has been implemented. The remediation plan shall include the nature and extent of the problem and the proposed remedy. After review, the Executive Director may require additional remediation measures.

3.7.1.2 General

In accordance with §330.371(d), the Executive Director may establish alternative schedules for demonstrating compliance with subsections §330.371(b) and §330.371(c).

In accordance with §330.371(e), the LFG monitoring and control program will continue for a period of 30 years after certification of final closure of the facility or until the owner or operator receives written authorization to reduce the program. Authorization to reduce LFG monitoring and control shall be based on demonstration that there is not potential for gas migration beyond the property boundary or into site structures. Demonstration shall be supported by collected data and additional studies, as required.

In accordance with §330.371(f), the LFG monitoring and control system shall be revised as needed to maintain current and effective LFG monitoring and control. Post-closure shall not interfere with the function of the LFG monitoring and control systems. Any underground utility trenches that cross the facility boundary shall be vented and monitored regularly.

3.7.2 Site Characteristics

In accordance with §330.371(b), the Landfill shall implement a routine LFG monitoring program to ensure the standards of §330.371(a) are met. The type and frequency of monitoring shall be based on the existing site conditions. The minimum frequency of monitoring shall be quarterly.

3.7.2.1 Soil Conditions

The site geologic conditions present at the Landfill are discussed in Appendix 3K - Geology.

3.7.2.2 Hydrogeologic Conditions

The hydrogeologic conditions present at the Landfill are discussed in Appendix 3K – Geology.

3.7.2.3 Hydraulic Conditions

Hydraulic conditions at the Landfill are discussed in Section 3.3 – Facility Surface Water Drainage Report.

3.7.2.4 Facility Structures within the Property Boundary

The Landfill has a permit boundary of approximately 347-acres~~ of which 277 acres will be available for waste placement~~. The existing structures located within the property boundary include the existing gatehouse (fee collection building), the maintenance building and a small storage building. The scale house building shall be monitored quarterly with a hand held gas meter at the base of each exterior wall and

ambient air. As part of the facility expansion, it is anticipated that a new equipment maintenance building and scale house will be constructed to the south of the existing buildings ***within*** ~~outside of~~ the property boundary (Drawing P3-17 in Appendix 3E). ***Any new Landfill structures will be monitored similarly to the existing structures.***

3.7.2.5 Underground Utilities

Underground utility lines that exist within the future disposal footprint of the landfill will be removed prior to the landfill expansion. No utility lines exist within the current disposal footprint of the landfill. Overhead lines provide electricity and telephone service to the buildings on-site. Consequently, monitoring or reporting of easement for buried utilities is not applicable.

3.7.2.6 Offsite Structures

~~As stated previously, as part of the facility expansion, it is anticipated that a new equipment maintenance building and scale house will be constructed to the south of the existing buildings outside of the property boundary (Drawing P3-17 in Appendix 3E). Any new landfill structures will be monitored similarly to the existing structures located within the property boundary.~~

In accordance with §330.371(h), since off-site habitable structures are located within 3,000 feet of the waste placement boundary, a permanent perimeter monitoring system is installed at the Landfill and is discussed in more detail below.

3.7.3 Existing Monitoring System

The existing LFG systems consists of gas monitoring probes (GMP) located along the perimeter of the landfill property as well as a landfill gas migration control system (GMCS) located along the western perimeter of the Landfill. The existing systems are shown on Drawing P3-43 in Appendix 3M and are described in further detail below.

3.7.3.1 Gas Monitoring Probes

GMP-1 through GMP-8 were installed in 1994. Description of the installation practices and sample boring and well installation logs are provide in the Landfill Gas Management Plan prepared by AGRA Earth & Environmental Group (AGRA) on April 8, 1994.

GMP-9 through GMP-17 were installed in 2001 by VIVA Environmental, Inc. (VIVA). Description of the installation practices, boring logs and well installation logs are provide in the Landfill Gas Management Plan prepared by VIVA on November 27, 2001.

In 2003, GMP-3 was replaced with GMP-3A and GMP-3 was decommissioned, plugged and abandoned. GMP-3A was installed adjacent to GMP-3 at a depth of approximately 67 feet below ground surface (bgs). The City also decommissioned, plugged and abandoned GMP-4, GMP-5, and GMP-6 based on previous TCEQ

approval due to the GMPs no longer falling on the outside perimeter of the landfill. The GMPs were abandoned in November 2003.

In 2004, GMP-18 and GMP-19 were installed to eventually replace GMP-2 and GMP-3A, respectively. The current locations of GMP-2 and GMP-3A are too close to the waste limits, and the locations of GMP-18 and GMP-19 are more suitable for gas monitoring at these two locations. GMP-2 and GMP-3A readings have returned to compliance due to the installation and operation of the active GMCS along a portion of the western perimeter as part of the gas migration remediation plan, but the GMPs have yet to be decommissioned, plugged and abandoned.

Temporary gas monitoring probes GMP-20, GMP-21, and GMP-22 were installed in 2006 to provide additional information on gas migration. Readings taken from the temporary probes have demonstrated that the gas migration issue has been mitigated. These probes are to be decommissioned, plugged and abandoned at a future date.

Boring and well installation logs for GMP-18 through GMP-22 are provided in the Landfill Gas Management Plan prepared by R.W. Beck in 2009.

The permanent Site Methane Monitoring Network currently consists of fourteen (14) GMPs (GMP-1 and GMP-7 through GMP-19) spaced approximately 1,000 feet apart. The GMPs were installed along the permitted area and property boundary. A review of on-site geological/soil data revealed little evidence of any laterally extensive stratographic units which could significantly influence migration of any gases produced within the landfill cells (AGRA, 1994). Additionally, geomembrane liner systems that will exist in future landfill cells should minimize potential for LFG migration away from the landfill footprint.

3.7.3.2 Passive Gas Vents

In June 2000, two passive venting wells (PV-1 and PV-2) were installed in order to intercept and vent methane gas prior to reaching GMP-2 and GMP-3. Both venting wells were installed to a depth of approximately 60-feet bgs in order to capture methane gas at depths where the majority of the elevated methane gas levels were detected and may be generated. In 2001, one vertical passive venting well (PV-3) was installed to a depth of 55-feet below grade.

In November of 2003, PV-1A and PV-2A were constructed to help mitigate the high methane readings recorded in GMP-2 and GMP-3. PV-1, PV-1A and PV-2A still exist within in the LFG management system; however, these wells were capped during the installation of the GMCS.

Five additional passive gas vents were installed in 2006 to provide additional gas venting in the area between GMP-2 and GMP-3. PV-3R was a replacement vent of PV-3 installed in 2001. PV-3 was abandoned in November 2003 as it falls within the landfill footprint and was no longer required to reduce methane levels measured at GMP-4.

PV-2 through PV-7 were converted into active gas extraction wells as part of the GMCS construction. The GMCS system is described in more detail in Section 3.7.3.3 below.

It should be noted that existing PVs (capped and active) will likely be decommissioned, plugged and abandoned prior to the vertical expansion on top of the existing landfill, assuming that this section of the existing landfill is no longer producing significant amounts of LFG at that time. However, in the event that the PVs still contain a significant amount of LFG, the PVs will be piped horizontally to the landfill perimeter for LFG venting/collection. PVs will not be extended vertically through the future expansion landfill geomembrane liner.

The locations of all active and abandoned GMPs and PVs are shown on Drawing P3-42 in Appendix 3M. Table 3.7-1 provides the approximate coordinates, elevations, and installed depths below ground surface at the time of installation of the GMPs and PVs of the existing system.

Table 3.7-1
Existing LFG Monitoring System Monitoring Points

Reference Point	Date Installed	Northing[1]	Easting[1]	Depth Below Ground Surface	Ground Elevation
GMP-1	1994	10738395.3	413850.0	55-feet	4086.41[2]
GMP-2	1994	10739603.6	413889.0	55-feet	4088.11[2]
GMP-3	1994		Abandoned		
GMP-3A	2003	10740576.6	413938.6	55-feet	4096.68[2]
GMP-4	1994		Abandoned		
GMP-5	1994		Abandoned		
GMP-6	1994		Abandoned		
GMP-7	1994	10738660.9	415896.4	10-feet	4072.61[2]
GMP-8	1994	10738332.2	414822.2	55-feet	4072.38[2]
GMP-9	2001	10738234.7	416875.7	55-feet	4078.55[2]
GMP-10	2001	10739228.3	417042.1	55-feet	4084.32[2]
GMP-11	2001	10740226.8	417080.2	55-feet	4087.33[2]
GMP-12	2001	10741225.2	417116.3	55-feet	4082.85[2]
GMP-13	2001	10742226.1	417153.5	55-feet	4082.21[2]
GMP-14	2001	10742561.4	416214.0	55-feet	4075.69[2]
GMP-15	2001	10742613.3	415216.7	55-feet	4067.69[2]
GMP-16	2001	10742664.4	414138.6	55-feet	4048.13[2]
GMP-17	2001	10741690.8	413989.8	55-feet	4056.37[2]
GMP-18	2004	10739597.9	413835.6	65-feet	4086.00[1]
GMP-19	2004	10740582.1	413863.0	65-feet	4085.39[1]
GMP-20	2006	10740260.4	413927.8	65-feet	4098.00[1]
GMP-21	2006	10739947.8	413908.1	65-feet	4094.53[1]
GMP-22	2006	10740120.7	413858.4	65-feet	4085.69[1]
PV-1	2000	10739588.0	413938.6	60-feet	4092.70[2]
PV-1A	2003	10739578.0	413938.6	55-feet	4090.00[1]
PV-2	2000	10740520.5	413971.0	60-feet	4101.28[2]
PV-2A	2003	10740550.5	413971.0	55-feet	4093.11[1]
PV-3	2001		Abandoned		
PV-3R	2006	10740452.5	414057.0	60-feet	4081.81[2]
PV-4	2006	10740279.1	414045.0	60-feet	4102.00[1]
PV-5	2006	10740094.4	414034.1	60-feet	4101.72[1]
PV-6	2006	10739890.3	414088.3	60-feet	4101.50[1]
PV-7	2006	10739641.6	414044.0	60-feet	4090.41[1]

[1] Northing and Easting locations and ground elevations provided are approximate and based on existing conditions locations and 2011 surveyed contours.
[2] Elevations obtained from VIVA, 2001.

3.7.3.3 Gas Migration Control System (Western Perimeter)

Existing gas monitoring probes (GMP-2, GMP-3, GMP-20, and GMP-21) located along the western perimeter of the Landfill have had periodic elevated methane readings above the regulatory limit of 5%. The Landfill was placed under enforcement action by the TCEQ to mitigate the affected GMPs due to the elevated methane readings.

In an attempt to reduce the methane readings, PV-1A and PV-2A were installed in 2003 and PV-3R through PV-7 were installed in 2006 along the western waste limit of the Landfill; however, the passive vents installed were not effective in controlling gas migration toward the affected GMPs. As a result, the City decided to install an active gas migration control system (GMCS) as part of the site gas remediation plan.

The GMCS is an active extraction system to control LFG migration in the affected area. The system is a partial active system, because it was installed only along a distance of approximately 1,000 feet over the northwestern portion of the unlined landfill. Existing PV-2 through PV-7 were converted into active gas extraction wells as part of the GMCS. In addition to the 6 converted extraction wells, the GMCS consists of LFG header and lateral pipes, a condensate sump and pump system, a blower/flare station, a condensate storage tank, and an air compressor system to power the condensate pump system. Since the GMCS system installation and subsequent start up in August of 2009, the GMP readings have been in compliance. If there are methane readings out of compliance in the future, further investigation will be conducted to ensure that the existing system is performing optimally. In the case that the system is running at peak performance and methane readings are still out of compliance, additional PVs may be added to the GMCS network. GMCS details are provided in the R.W. Beck Landfill Gas Management Plan of 2009.

3.7.4 Potential Future LFG Management System

3.7.4.1 NSPS Requirements

Pursuant to 40 CFR Part 60, Subpart Cc §60.33c, "a State plan shall include control of MSW landfill emissions at each MSW landfill meeting the following three conditions:

1. The landfill has accepted waste at any time since November 8, 1987, or has additional design capacity available for future waste deposition;
2. The landfill has a design capacity greater than or equal to 2.5 million megagrams and 2.5 million cubic meters. The landfill may calculate design capacity in either megagrams or cubic meters for comparison with the exemption values. Any density conversions shall be documented and submitted with the design capacity report; and,
3. The landfill has a nonmethane organic compound emission rate of 50 megagrams per year or more."

Design Capacity

One threshold for NSPS requirements is the Landfill having a design capacity of 2.5 million megagrams (Mg) or cubic meters. The Landfill design capacity is over the NSPS threshold of 2.5 million Mg.

NMOCs

Because the Landfill is over the design capacity threshold, nonmethane organic compound (NMOC) monitoring is required at a Tier II level. The last NMOC monitoring event conducted at the Landfill was completed in March 2007. The results from the NMOC monitoring indicate that the maximum NMOC concentration will occur in year 2047 at a concentration of 34.69 Mg (under the 50 Mg threshold). According to the 2007 test results, the Landfill is currently under the annual air emissions threshold of the Federal New Source Performance Standards (NSPS), and as a result, there is no present requirement for the City to install a LFG collection and control system (GCCS) covering the entire landfill. The latest NMOC results are provided in Appendix 3M.

NMOC monitoring will continue, as necessary, in accordance with the site air permit and the Landfill will continue to evaluate the need for an active GCCS based on future NMOC monitoring results.

3.7.4.2 Active Gas Collection and Control System

Although the Landfill is currently not required to install an active GCCS system, the following system has been designed with the assumption that the Landfill will either eventually have to comply with NSPS standards, or will choose to install an active GCCS voluntarily to further landfill gas to energy efforts.

The designed active GCCS will consist of a series of wells and piping used to convey LFG to an open flare station for combustion or to a landfill-gas-to-energy conversion system. The GCCS will be constructed in a similar manner to the GMCS and may include some of the same components as the GMCS. GCCS components will include:

- Header/Manifold
- Lateral
- Vertical Gas Wells (GW)
- Cleanout Stations
- Condensate Sumps
- Flare Station

As shown on Drawing P3-39 in Appendix 3M, the GWs were designed at a radius of influence (ROI) of 150-feet. The ROI was developed based on previous experience with similar type soils (silty sand/sandy) and drier waste moisture content. The actual location of the GWs may vary dependent on site conditions at the time of installation.

3.7.4.3 Existing System Modifications

Upon Landfill expansion, it is anticipated that GMP-7 will be removed from the monitoring system and that GMP-23 will replace GMP-7 in the monitoring network (Drawing P3-43 in Appendix 3M). GMP-23 will be located on the outside of the Landfill limits, but inside the property boundary. GMP-7 will be decommissioned, plugged and abandoned upon installation of GMP-23. GMP-23 will be installed following the guidelines set forth in Section 4.2 of the AGRA Landfill Gas Monitoring Plan, 1994 (Appendix 3M, Attachment 4).

3.7.5 Monitoring Plan

3.7.5.1 Perimeter Monitoring

Perimeter Monitoring Network

The LFG monitoring probe network at the Landfill includes a total of fourteen existing LFG monitoring probes (GMP-1 and GMP-7 through GMP-19) located along the perimeter of the waste fill area. Locations of the existing GMPs are shown on Drawing P3-43 in Appendix 3M. As mentioned previously, GMP-7 will be replaced with GMP-23 in the permanent monitoring network.

Landfill Gas Monitoring Probes

LFG monitoring probes have been installed along the perimeter of the waste fill area. Boring logs and typical construction details for the GMPs have been provided in previous versions of the LFG Management Plan (R.W. Beck 2009, VIVA 2001, AGRA 1994) which are provided in Appendix 3M, Attachment 4. Future LFG monitoring probes will be installed in accordance with the detail shown on Drawing P3-44 in Appendix 3M.

Monitoring Procedures

During each monitoring event, the GMPs will be monitored for the following parameters:

- Probe gas pressure at each probe;
- Methane gas concentrations at each probe;
- Barometric pressure during the monitoring event; and
- Ambient temperature during the monitoring event.

Monitoring for gas composition and pressure will be performed using a portable combustible gas indicator capable of measuring the above parameters. Prior to the start of monitoring, the tester shall calibrate monitoring instruments in accordance with the manufacturer's specifications. The instrument is factory calibrated semi-annually. The tester should also record time, temperature, barometric pressure, and weather conditions prior to the start of the monitoring period. Each GMP shall be monitored using the following monitoring procedures:

- Check GMP's integrity;
- Determine pressure within sealed monitoring tube;
- Determine methane concentrations at each location; and
- Record all data on the LFG Monitoring Report Form (Appendix 3M).

Maintenance Procedures

Each time LFG monitoring is conducted, the sampler will inspect the integrity of the LFG monitoring probes. The sampler will record pertinent information on the LFG Monitoring Report Form provided in Appendix 3M. The LFG Monitoring Report Form will be kept in the Site Operating Record. The sampler will perform the following at each monitoring event:

- Verify that the GMP identification number is clearly labeled on the outer casing or lid;
- Verify that the protective casing is intact and is not bent or excessively corroded;
- Verify that the protective barrier pipes are intact;
- Verify that the working pad is intact;
- Verify that the lock is functional;
- Verify that the hinged cover is in working order; and
- Verify that the inner casing is intact.

If damage or excessive wear to the LFG monitoring probe is observed, it will be reported to the landfill manager and repaired within 30 days of the date damage is observed. If it is not possible to repair the GMP, the LFG monitoring probe will be decommissioned and replaced within 60 days from the TCEQ approval date of the permit modification requesting replacement of the GMP. Upon completion of the replacement GMP, an as-built documentation report including boring and well installation logs will be submitted to the TCEQ.

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.2 GMCS/GCCS Monitoring

GMCS Monitoring Network

The gas migration control system network currently consists of 6 active gas wells that were converted from passive gas vents (PV-2 to PV-7). The system was installed to mitigate methane exceedance detected in GMP-2, GMP-3, GMP-20 and GMP-21 along the western perimeter of the unlined landfill area. In the event that the levels of methane increase above regulatory standards in the affected GMPs, expansion of the existing GMCS may occur. It is anticipated that this system will eventually be replaced by the GCCS network.

GCCS Monitoring Network

The GCCS is anticipated to be installed either upon the landfill reaching NSPS standards requirements or on a voluntary basis. This is dependent both on the current permitted waste capacity (which the landfill is currently exceeding the limits of 2.5 million megagrams or 2.5 million cubic meters) and the current NMOC concentration within the LFG. As described in Section 3.7.4.1, the actual timing for the Landfill reaching NSPS standards is currently unknown and will be dependent on future NMOC monitoring.

Monitoring Procedures

The GMCS and GCCS are designed to collect LFG and prevent fugitive emissions from the Landfill. Since the rate of LFG production within the landfill varies, the amount of gas withdrawn by the GMCS/GCCS GWs should also be adjusted. During each monitoring event, the Flare (and/or potential gas-to-energy conversion system) will be monitored and the GWs will likely be monitored for the following parameters:

- Gas flow at each location;
- Gas pressure at each location;
- Gas temperature at each location;
- Methane gas concentrations at each location;
- Oxygen gas concentrations at each location;
- Barometric pressure during the monitoring event; and
- Ambient temperature during the monitoring event.

Monitoring for gas composition, pressure, and temperature will be performed using a portable combustible gas indicator capable of measuring the above parameters. Prior to the start of monitoring, the tester shall calibrate monitoring instruments in accordance with the manufacturer's specifications. The GMCS/GCCS will likely be sampled using the following sampling procedure:

- Record date, time and current weather conditions;
- Record initial data from Flare skid;
- Perform GW maintenance check at each GW;
- Record above parameters at each GW;
- Adjust flow through the wellhead at each GW based on the methane and oxygen measurements (if necessary); and
- Record end data from Flare skid.

Maintenance Procedures

When the GCMS/GCCS monitoring includes the monitoring of the GWs, the sampler will inspect the integrity of the GWs. The sampler will record pertinent information on the LFG Monitoring Report Form which will be placed in the Site Operating Record. The sampler will also observe the wellhead during the monitoring event to

ensure no damage has occurred to the wellhead. If damage or excessive wear to the GW or wellhead is observed, it will be reported to the landfill manager and repaired within 30 days of the date damage is observed. If it is not possible to repair the GW, the Landfill will evaluate the effectiveness of replacing the GW within the gas collection system. If the GW is replaced, an as-built documentation report will be submitted to the TCEQ including boring and well installation logs.

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.3 Facility Structures Monitoring

Monitoring Procedures

On-site buildings and structures designed for human occupation will be monitored, at a minimum, quarterly with a portable combustible gas indicator. The buildings shall be monitored quarterly with a hand held gas meter at the base of each exterior wall and also the ambient air.

If methane concentration exceeded allowable limits within structures, the building will be immediate evacuated and ventilated by opening doors and windows and placing a portable blower to blow clean air into the building. Notification consistent with the procedures outlined in Section 3.7.6.2 will be implemented immediately.

Maintenance Procedures

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.4 Recordkeeping/Reporting

Field monitoring data records will be placed in the Site Operating Record and maintained onsite for inspection. Field data will be recorded on the LFG Monitoring Report Form provided in Appendix 3M.

3.7.5.5 Monitoring Frequency

LFG monitoring probes and facility structures will be monitored quarterly at a minimum. The facility will monitor the locations more frequently if monitoring results indicate that LFG migration is occurring or is accumulating in the structures.

GMCS monitoring is required on a monthly basis; however, Landfill personnel typically monitor on a weekly basis. GCCS monitoring will occur similarly to the GMCS monitoring and shall comply with 40 CFR Part 60, Subpart WWW §60.756.

3.7.6 Action Plan

3.7.6.1 Initial Response Measures

This action plan has been prepared for the protection of human health in the event concentrations of methane exceed allowable limits as required under 30 TAC §330.371. The action plan will address methane level exceedance measurements for both buildings and perimeter monitoring probes.

Emergency Action

As defined in Section 3.7.1.1, the first action in the event that methane is detected at levels above regulatory limits is to protect human health. The following actions will be taken to protect human health dependent on the exceedance location.

Permit Boundary

If methane levels are detected above the regulatory limit in one of the GMPs, the landfill manager will be notified. The immediate emergency response measure will be for the landfill manager to determine if any nearby buildings or structures (including offsite) are at risk and if evacuation of the buildings or structures should be requested.

Structures

If methane concentration exceeded allowable limits within structures, the building will be immediate evacuated and ventilated by opening doors and windows and placing a portable blower to blow clean air into the building. The landfill manager will be notified of the exceedance, and personnel will not be allowed to reenter the building until additional measurements are taken.

Verification Procedures

Once emergency action measures have been taken to protect human health, the landfill manager will require monitoring personnel to begin verification procedures. Verification procedures are intended to determine if the methane levels detected are accurate, or if erroneous levels have been detected.

Permit Boundary

Verification of the detected methane levels above regulatory limits in the GMPs will be conducted within 24 hours using the following procedures:

- Recalibrate gas detection equipment according to manufacturer's recommendations;
- After recalibration of the gas detection equipment, recheck the methane concentration in the GMP; and
- Recheck the methane concentration again within 7 days of the initial reading.

If the measured concentrations of methane are not above regulatory limits in the verification procedure, routine monitoring procedures will resume.

If the follow-up readings suggest that there are methane gas levels exceeding the regulatory limits, notification and remediate procedures must be implemented as described in Section 3.7.6.2 and Section 3.7.7.

Structures

Verification of detected methane levels in the facility structures shall be conducted within 24 hours of the exceedance by monitoring methane levels throughout the structure using a portable gas meter. Readings will be taken in each room and in any confined spaces. If any natural gas appliances exist in the structure, they should be checked for leaks.

If concentrations of methane above the regulatory limit are not detected, personnel may return to the structure. Daily follow-up verification readings must be made for a period of one week after the exceedance measurement. If the follow-up readings suggest that there are methane gas levels exceeding the regulatory limits, notification and remediate procedures must be implemented as described in Section 3.7.6.2 and Section 3.7.7.

3.7.6.2 Notification Procedures

When methane concentrations are detected above the regulatory limit, notification will be made immediately in accordance with §330.371. Within seven days from the date of an initial reading above allowable limits, the owner shall place in the Site Operating Record:

- Concentration of methane gas levels detected as well as time, date, and location;
- Description of steps taken to protect human health; and
- Information regarding the notifications to the Executive Director, local and county officials, emergency officials, and the public of the exceedance;

Within 60 days, the City shall take the following actions:

- Submit and implement a remediation plan for the methane gas releases that describes the nature and extent of gas migration and proposed remedy to the Executive Director; and
- Provide notification to the Executive Director that the remediation plan has been implemented.
- Place a copy of the remediation plan in the Site Operating Record.

3.7.7 Remediation Plan

If verification procedures confirm that the methane levels detected are above the regulatory limits in either an onsite structure or GMP, remediation actions shall be implemented within 60 days of detection. The initial remediation action will be an investigation of the cause of the exceeding methane levels. The investigation will be completed using all or part of the following items:

- Additional gas sampling at the landfill to determine concentrations of methane;

- Soil gas sampling to determine the extent of gas migration beyond the permitted landfill facility;
- Additional or increased GMP monitoring in the area of exceedance;
- Installation of additional GMPs or PVs in the area of exceedance; and
- Installation/expansion of an active LFG collection and control system.

Based on the results of the investigation, the Landfill will determine the appropriate course of action to ensure future methane concentration levels are below regulatory standards. In accordance with 30 TAC §330.371, a remediation plan describing the nature and extent of the problem and the proposed remedy will be submitted to the Executive Director within 60 days of detection that notifies the Executive Director of the plan and that the plan has been implemented. Copies of the remediation plan will be kept in the Site Operation Record. If the remediation plan includes any changes to the LFG Management Plan, approval will be received from the TCEQ prior to implementation.

3.7.8 Backup Plan

This backup plan will be applicable under the assumption that the active GCCS is required to be installed under NSPS and has been developed in accordance with 30 TAC §330.371(g)(3). In the event that the GMCS/GCCS breaks down, the backup plan will be to repair the GMCS/GCCS as soon as possible, dependent on weather, contractor, material, and equipment availability. During the repair period, monitoring frequency on the site GMPs will increase to monitoring levels determined at the time of repair.

3.7.1 Introduction

This landfill gas (LFG) management plan (Plan) has been developed as required by 30 TAC §330.63(g) for the Landfill located in El Paso, Texas. This LFG management plan is consistent with the requirements set forth in 30 TAC §330.371 and provides a site-specific approach for completing LFG management. This Plan describes the existing and ***potential future*** ~~proposed~~ LFG management system and discusses the operation and monitoring of these systems, including verification of results, notification procedures, and possible remediation activities. Landfill Gas Management Plans developed by R.W. Beck, dated April 3, 2009, VIVA Environmental, Inc, dated November 27, 2001, and AGRA Earth and Environmental Group, dated April 8, 1994, were used in the development of the following section and are included ***for reference*** as Appendix 3M, Attachment 4.

3.7.1.1 Purpose

Compliance with §330.371(a) requires landfills to implement a routine LFG monitoring program to ensure that the following conditions are met:

- Concentrations of methane gas does not exceed 1.25% by volume in facility structures (excluding gas control or recovery system components); and
- Concentrations of methane gas does not exceed 5% by volume in monitoring points, probes, or other matrices at the facility boundary.

The purpose of this plan is to provide guidelines for the management of LFG and to provide guidance if the levels of methane exceed the limits specified above. Pursuant to §330.371(c), if methane levels are exceeded, the owner or operator shall take the following steps:

- Ensure protection of human health, and notify the Executive Director, local and county officials, emergency officials, and the public of the exceedance;
- Within seven days of the detection, operating records shall be updated to reflect the concentration of methane gas levels detected and the steps that were taken to protect human health; and
- Within 60 days of exceedance, a remediation plan shall be implemented to control methane gas releases. Copies of the remediation plan shall be placed in the operating record, provided to the Executive Director, and notification to the Executive Director that the plan has been implemented. The remediation plan shall include the nature and extent of the problem and the proposed remedy. After review, the Executive Director may require additional remediation measures.

3.7.1.2 General

In accordance with §330.371(d), the Executive Director may establish alternative schedules for demonstrating compliance with subsections §330.371(b) and §330.371(c).

In accordance with §330.371(e), the LFG monitoring and control program will continue for a period of 30 years after certification of final closure of the facility or until the owner or operator receives written authorization to reduce the program. Authorization to reduce LFG monitoring and control shall be based on demonstration that there is not potential for gas migration beyond the property boundary or into site structures. Demonstration shall be supported by collected data and additional studies, as required.

In accordance with §330.371(f), the LFG monitoring and control system shall be revised as needed to maintain current and effective LFG monitoring and control. Post-closure shall not interfere with the function of the LFG monitoring and control systems. Any underground utility trenches that cross the facility boundary shall be vented and monitored regularly.

3.7.2 Site Characteristics

In accordance with §330.371(b), the Landfill shall implement a routine LFG monitoring program to ensure the standards of §330.371(a) are met. The type and frequency of monitoring shall be based on the existing site conditions. The minimum frequency of monitoring shall be quarterly.

3.7.2.1 Soil Conditions

The site geologic conditions present at the Landfill are discussed in Appendix 3K - Geology.

3.7.2.2 Hydrogeologic Conditions

The hydrogeologic conditions present at the Landfill are discussed in Appendix 3K – Geology.

3.7.2.3 Hydraulic Conditions

Hydraulic conditions at the Landfill are discussed in Section 3.3 – Facility Surface Water Drainage Report.

3.7.2.4 Facility Structures within the Property Boundary

The Landfill has a permit boundary of approximately ***347*** ~~327~~ -acres of which 277-acres will be available for waste placement. The existing structures located within the property boundary include the existing gatehouse (fee collection building), the maintenance building and a small storage building. The scale house building shall be monitored quarterly with a hand held gas meter at the base of each exterior wall and

ambient air. As part of the facility expansion, it is anticipated that a new equipment maintenance building and scale house will be constructed to the south of the existing buildings outside of the property boundary (Drawing P3-17 in Appendix 3E).

3.7.2.5 Underground Utilities

Underground utility lines that exist within the future disposal footprint of the landfill will be removed prior to the landfill expansion. No utility lines exist within the current disposal footprint of the landfill. Overhead lines provide electricity and telephone service to the buildings on-site. Consequently, monitoring or reporting of easement for buried utilities is not applicable.

3.7.2.6 Offsite Structures

As stated previously, as part of the facility expansion, it is anticipated that a new equipment maintenance building and scale house will be constructed to the south of the existing buildings outside of the property boundary (Drawing P3-17 in Appendix 3E). Any new landfill structures will be monitored similarly to the existing structures located within the property boundary.

In accordance with §330.371(h), since off-site habitable structures are located within 3,000 feet of the waste placement boundary, a permanent perimeter monitoring system is installed at the Landfill and is discussed in more detail below.

3.7.3 Existing Monitoring System

The existing LFG systems consists of gas monitoring probes (GMP) located along the perimeter of the landfill property as well as a landfill gas migration control system (GMCS) located along the western perimeter of the Landfill. The existing systems are shown on Drawing P3-43 in Appendix 3M and are described in further detail below.

3.7.3.1 Gas Monitoring Probes

GMP-1 through GMP-8 were installed in 1994. Description of the installation practices and sample boring and well installation logs are provide in the Landfill Gas Management Plan prepared by AGRA Earth & Environmental Group (AGRA) on April 8, 1994.

GMP-9 through GMP-17 were installed in 2001 by VIVA Environmental, Inc. (VIVA). Description of the installation practices, boring logs and well installation logs are provide in the Landfill Gas Management Plan prepared by VIVA on November 27, 2001.

In 2003, GMP-3 was replaced with GMP-3A and GMP-3 was decommissioned, plugged and abandoned. GMP-3A was installed adjacent to GMP-3 at a depth of approximately 67 feet below ground surface (bgs). The City also decommissioned, plugged and abandoned GMP-4, GMP-5, and GMP-6 based on previous TCEQ approval due to the GMPs no longer falling on the outside perimeter of the landfill. The GMPs were abandoned in November 2003.

In 2004, GMP-18 and GMP-19 were installed to eventually replace GMP-2 and GMP-3A, respectively. The current locations of GMP-2 and GMP-3A are too close to the waste limits, and the locations of GMP-18 and GMP-19 are more suitable for gas monitoring at these two locations. GMP-2 and GMP-3A readings have returned to compliance due to the installation and operation of the active GMCS along a portion of the western perimeter as part of the gas migration remediation plan, but the GMPs have yet to be decommissioned, plugged and abandoned.

Temporary gas monitoring probes GMP-20, GMP-21, and GMP-22 were installed in 2006 to provide additional information on gas migration. Readings taken from the temporary probes have demonstrated that the gas migration issue has been mitigated. These probes are to be decommissioned, plugged and abandoned at a future date.

Boring and well installation logs for GMP-18 through GMP-22 are provided in the Landfill Gas Management Plan prepared by R.W. Beck in 2009.

The permanent Site Methane Monitoring Network currently consists of fourteen (14) GMPs (GMP-1 and GMP-7 through GMP-19) spaced approximately 1,000 feet apart. The GMPs were installed along the permitted area and property boundary. A review of on-site geological/soil data revealed little evidence of any laterally extensive stratographic units which could significantly influence migration of any gases produced within the landfill cells (AGRA, 1994). Additionally, geomembrane liner systems that will exist in future landfill cells should minimize potential for LFG migration away from the landfill footprint.

3.7.3.2 Passive Gas Vents

In June 2000, two passive venting wells (PV-1 and PV-2) were installed in order to intercept and vent methane gas prior to reaching GMP-2 and GMP-3. Both venting wells were installed to a depth of approximately 60-feet bgs in order to capture methane gas at depths where the majority of the elevated methane gas levels were detected and may be generated. In 2001, one vertical passive venting well (PV-3) was installed to a depth of 55-feet below grade.

In November of 2003, PV-1A and PV-2A were constructed to help mitigate the high methane readings recorded in GMP-2 and GMP-3. PV-1, PV-1A and PV-2A still exist within in the LFG management system; however, these wells were capped during the installation of the GMCS.

Five additional passive gas vents were installed in 2006 to provide additional gas venting in the area between GMP-2 and GMP-3. PV-3R was a replacement vent of PV-3 installed in 2001. PV-3 was abandoned in November 2003 as it falls within the landfill footprint and was no longer required to reduce methane levels measured at GMP-4.

PV-2 through PV-7 were converted into active gas extraction wells as part of the GMCS construction. The GMCS system is described in more detail in Section 3.7.3.3 below.

It should be noted that existing PVs (capped and active) will likely be decommissioned, plugged and abandoned prior to the vertical expansion on top of the

existing landfill, assuming that this section of the existing landfill is no longer producing significant amounts of LFG at that time. However, in the event that the PVs still contain a significant amount of LFG, the PVs will be piped horizontally to the landfill perimeter for LFG venting/collection. PVs will not be extended vertically through the future expansion landfill geomembrane liner.

The locations of all active and abandoned GMPs and PVs are shown on Drawing P3-42 in Appendix 3M. Table 3.7-1 provides the approximate coordinates, elevations, and installed depths below ground surface at the time of installation of the GMPs and PVs of the existing system.

Table 3.7-1
Existing LFG Monitoring System Monitoring Points

Reference Point	Date Installed	Northing[1]	Easting[1]	Depth Below Ground Surface	Ground Elevation
GMP-1	1994	10738395.3	413850.0	55-feet	4086.41[2]
GMP-2	1994	10739603.6	413889.0	55-feet	4088.11[2]

GMP-17	2001	10741690.8	413989.8	55-feet	4056.37[2]
GMP-18	2004	10739597.9	413835.6	65-feet	4086.00[1]
GMP-19	2004	10740582.1	413863.0	65-feet	4085.39[1]
GMP-20	2006	10740260.4	413927.8	65-feet	4098.00[1]
GMP-21	2006	10739947.8	413908.1	65-feet	4094.53[1]
GMP-22	2006	10740120.7	413858.4	65-feet	4085.69[1]
PV-1	2000	10739588.0	413938.6	60-feet	4092.70[2]
PV-1A	2003	10739578.0	413938.6	55-feet	4090.00[1]
PV-2	2000	10740520.5	413971.0	60-feet	4101.28[2]
PV-2A	2003	10740550.5	413971.0	55-feet	4093.11[1]
PV-3	2001		Abandoned		
PV-3R	2006	10740452.5	414057.0	60-feet	4081.81[2]
PV-4	2006	10740279.1	414045.0	60-feet	4102.00[1]
PV-5	2006	10740094.4	414034.1	60-feet	4101.72[1]
PV-6	2006	10739890.3	414088.3	60-feet	4101.50[1]
PV-7	2006	10739641.6	414044.0	60-feet	4090.41[1]

[1] Northing and Easting locations and ground elevations provided are approximate and based on existing conditions locations and 2011 surveyed contours.
[2] Elevations obtained from VIVA, 2001.

3.7.3.3 Gas Migration Control System (Western Perimeter)

Existing gas monitoring probes (GMP-2, GMP-3, GMP-20, and GMP-21) located along the western perimeter of the Landfill have had periodic elevated methane readings above the regulatory limit of 5%. The Landfill was placed under enforcement action by the TCEQ to mitigate the affected GMPs due to the elevated methane readings.

In an attempt to reduce the methane readings, PV-1A and PV-2A were installed in 2003 and PV-3R through PV-7 were installed in 2006 along the western waste limit of the Landfill; however, the passive vents installed were not effective in controlling gas migration toward the affected GMPs. As a result, the City decided to install an active gas migration control system (GMCS) as part of the site gas remediation plan.

The GMCS is an active extraction system to control LFG migration in the affected area. The system is a partial active system, because it was installed only along a distance of approximately 1,000 feet over the northwestern portion of the unlined landfill. Existing PV-2 through PV-7 were converted into active gas extraction wells as part of the GMCS. In addition to the 6 converted extraction wells, the GMCS consists of LFG header and lateral pipes, a condensate sump and pump system, a blower/flare station, a condensate storage tank, and an air compressor system to power the condensate pump system. Since the GMCS system installation and subsequent start up in August of 2009, the GMP readings have been in compliance. If there are methane readings out of compliance in the future, further investigation will be conducted to ensure that the existing system is performing optimally. In the case that the system is running at peak performance and methane readings are still out of compliance, additional PVs may be added to the GMCS network. GMCS details are provided in the R.W. Beck Landfill Gas Management Plan of 2009.

3.7.4 *Potential Future* ~~Proposed~~ LFG Management System

3.7.4.1 NSPS Requirements

Pursuant to 40 CFR Part 60, Subpart Cc §60.33c, "a State plan shall include control of MSW landfill emissions at each MSW landfill meeting the following three conditions:

1. The landfill has accepted waste at any time since November 8, 1987, or has additional design capacity available for future waste deposition;
2. The landfill has a design capacity greater than or equal to 2.5 million megagrams and 2.5 million cubic meters. The landfill may calculate design capacity in either megagrams or cubic meters for comparison with the exemption values. Any density conversions shall be documented and submitted with the design capacity report; and,
3. The landfill has a nonmethane organic compound emission rate of 50 megagrams per year or more."

Design Capacity

One threshold for NSPS requirements is the Landfill having a design capacity of 2.5 million megagrams (Mg) or cubic meters. The Landfill design capacity is over the NSPS threshold of 2.5 million Mg.

NMOCs

Because the Landfill is over the design capacity threshold, nonmethane organic compound (NMOC) monitoring is required at a Tier II level. The last NMOC monitoring event conducted at the Landfill was completed in March 2007. The results from the NMOC monitoring indicate that the maximum NMOC concentration will occur in year 2047 at a concentration of 34.69 Mg (under the 50 Mg threshold). According to the 2007 test results, the Landfill is currently under the annual air emissions threshold of the Federal New Source Performance Standards (NSPS), and as a result, there is no present requirement for the City to install a LFG collection and control system (GCCS) covering the entire landfill. The latest NMOC results are provided in Appendix 3M.

NMOC monitoring will continue, as necessary, in accordance with the site air permit and the Landfill will continue to evaluate the need for an active GCCS based on future NMOC monitoring results.

3.7.4.2 Active Gas Collection and Control System

Although the Landfill is currently not required to install an active GCCS system, the following system has been designed with the assumption that the Landfill will either eventually have to comply with NSPS standards, or will choose to install an active GCCS voluntarily to further landfill gas to energy efforts.

The designed active GCCS will consist of a series of wells and piping used to convey LFG to an open flare station for combustion or to a landfill-gas-to-energy conversion system. The GCCS will be constructed in a similar manner to the GMCS and may include some of the same components as the GMCS. GCCS components will include:

- Header/Manifold
- Lateral
- Vertical Gas Wells (GW)
- Cleanout Stations
- Condensate Sumps
- Flare Station

As shown on Drawing P3-39 in Appendix 3M, the GWs were designed at a radius of influence (ROI) of 150-feet. The ROI was developed based on previous experience with similar type soils (silty sand/sandy) and drier waste moisture content. The actual location of the GWs may vary dependent on site conditions at the time of installation.

3.7.4.3 Existing System Modifications

Upon Landfill expansion, it is anticipated that GMP-7 will be removed from the monitoring system and that GMP-23 will replace GMP-7 in the monitoring network (Drawing P3-43 in Appendix 3M). GMP-23 will be located on the outside of the Landfill limits, but inside the property boundary. GMP-7 will be decommissioned, plugged and abandoned upon installation of GMP-23. GMP-23 will be installed following the guidelines set forth in Section 4.2 of the AGRA Landfill Gas Monitoring Plan, 1994 (Appendix 3M, Attachment 4).

3.7.5 Monitoring Plan

3.7.5.1 Perimeter Monitoring

Perimeter Monitoring Network

The LFG monitoring probe network at the Landfill includes a total of fourteen existing LFG monitoring probes (GMP-1 and GMP-7 through GMP-19) located along the perimeter of the waste fill area. Locations of the existing GMPs are shown on Drawing P3-43 in Appendix 3M. As mentioned previously, GMP-7 will be replaced with GMP-23 in the permanent monitoring network.

Landfill Gas Monitoring Probes

LFG monitoring probes have been installed along the perimeter of the waste fill area. Boring logs and typical construction details for the GMPs have been provided in previous versions of the LFG Management Plan (R.W. Beck 2009, VIVA 2001, AGRA 1994) which are provided in Appendix 3M, Attachment 4. Future LFG monitoring probes will be installed in accordance with the detail shown on Drawing P3-44 in Appendix 3M.

Monitoring Procedures

During each monitoring event, the GMPs will be monitored for the following parameters:

- Probe gas pressure at each probe;
- Methane gas concentrations at each probe;
- Barometric pressure during the monitoring event; and
- Ambient temperature during the monitoring event.

Monitoring for gas composition and pressure will be performed using a portable combustible gas indicator capable of measuring the above parameters. Prior to the start of monitoring, the tester shall calibrate monitoring instruments in accordance with the manufacturer's specifications. The instrument is factory calibrated semi-annually. The tester should also record time, temperature, barometric pressure, and weather conditions prior to the start of the monitoring period. Each GMP shall be monitored using the following monitoring procedures:

- Check GMP's integrity;
- Determine pressure within sealed monitoring tube;
- Determine methane concentrations at each location; and
- Record all data on the LFG Monitoring Report Form (Appendix 3M).

Maintenance Procedures

Each time LFG monitoring is conducted, the sampler will inspect the integrity of the LFG monitoring probes. The sampler will record pertinent information on the LFG Monitoring Report Form provided in Appendix 3M. The LFG Monitoring Report Form will be kept in the Site Operating Record. The sampler will perform the following at each monitoring event:

- Verify that the GMP identification number is clearly labeled on the outer casing or lid;
- Verify that the protective casing is intact and is not bent or excessively corroded;
- Verify that the protective barrier pipes are intact;
- Verify that the working pad is intact;
- Verify that the lock is functional;
- Verify that the hinged cover is in working order; and
- Verify that the inner casing is intact.

If damage or excessive wear to the LFG monitoring probe is observed, it will be reported to the landfill manager and repaired within 30 days of the date damage is observed. If it is not possible to repair the GMP, the LFG monitoring probe will be decommissioned and replaced within 60 days from the TCEQ approval date of the permit modification requesting replacement of the GMP. Upon completion of the replacement GMP, an as-built documentation report including boring and well installation logs will be submitted to the TCEQ.

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.2 GMCS/GCCS Monitoring

GMCS Monitoring Network

The gas migration control system network currently consists of 6 active gas wells that were converted from passive gas vents (PV-2 to PV-7). The system was installed to mitigate methane exceedance detected in GMP-2, GMP-3, GMP-20 and GMP-21 along the western perimeter of the unlined landfill area. In the event that the levels of methane increase above regulatory standards in the affected GMPs, expansion of the existing GMCS may occur. It is anticipated that this system will eventually be replaced by the GCCS network.

GCCS Monitoring Network

The GCCS is anticipated to be installed either upon the landfill reaching NSPS standards requirements or on a voluntary basis. This is dependent both on the current permitted waste capacity (which the landfill is currently exceeding the limits of 2.5 million megagrams or 2.5 million cubic meters) and the current NMOC concentration within the LFG. As described in Section 3.7.4.1, the actual timing for the Landfill reaching NSPS standards is currently unknown and will be dependent on future NMOC monitoring.

Monitoring Procedures

The GMCS and GCCS are designed to collect LFG and prevent fugitive emissions from the Landfill. Since the rate of LFG production within the landfill varies, the amount of gas withdrawn by the GMCS/GCCS GWs should also be adjusted. During each monitoring event, the Flare (and/or potential gas-to-energy conversion system) will be monitored and the GWs will likely be monitored for the following parameters:

- Gas flow at each location;
- Gas pressure at each location;
- Gas temperature at each location;
- Methane gas concentrations at each location;
- Oxygen gas concentrations at each location;
- Barometric pressure during the monitoring event; and
- Ambient temperature during the monitoring event.

Monitoring for gas composition, pressure, and temperature will be performed using a portable combustible gas indicator capable of measuring the above parameters. Prior to the start of monitoring, the tester shall calibrate monitoring instruments in accordance with the manufacturer's specifications. The GMCS/GCCS will likely be sampled using the following sampling procedure:

- Record date, time and current weather conditions;
- Record initial data from Flare skid;
- Perform GW maintenance check at each GW;
- Record above parameters at each GW;
- Adjust flow through the wellhead at each GW based on the methane and oxygen measurements (if necessary); and
- Record end data from Flare skid.

Maintenance Procedures

When the GCMS/GCCS monitoring includes the monitoring of the GWs, the sampler will inspect the integrity of the GWs. The sampler will record pertinent information on the LFG Monitoring Report Form which will be placed in the Site Operating Record. The sampler will also observe the wellhead during the monitoring event to

ensure no damage has occurred to the wellhead. If damage or excessive wear to the GW or wellhead is observed, it will be reported to the landfill manager and repaired within 30 days of the date damage is observed. If it is not possible to repair the GW, the Landfill will evaluate the effectiveness of replacing the GW within the gas collection system. If the GW is replaced, an as-built documentation report will be submitted to the TCEQ including boring and well installation logs.

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.3 Facility Structures Monitoring

Monitoring Procedures

On-site buildings and structures designed for human occupation will be monitored, at a minimum, quarterly with a portable combustible gas indicator. The buildings shall be monitored quarterly with a hand held gas meter at the base of each exterior wall and also the ambient air.

If methane concentration exceeded allowable limits within structures, the building will be immediate evacuated and ventilated by opening doors and windows and placing a portable blower to blow clean air into the building. Notification consistent with the procedures outlined in Section 3.7.6.2 will be implemented immediately.

Maintenance Procedures

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.4 Recordkeeping/Reporting

Field monitoring data records will be placed in the Site Operating Record and maintained onsite for inspection. Field data will be recorded on the LFG Monitoring Report Form provided in Appendix 3M.

3.7.5.5 Monitoring Frequency

LFG monitoring probes and facility structures will be monitored quarterly at a minimum. The facility will monitor the locations more frequently if monitoring results indicate that LFG migration is occurring or is accumulating in the structures.

GMCS monitoring is required on a monthly basis; however, Landfill personnel typically monitor on a weekly basis. GCCS monitoring will occur similarly to the GMCS monitoring and shall comply with 40 CFR Part 60, Subpart WWW §60.756.

3.7.6 Action Plan

3.7.6.1 Initial Response Measures

This action plan has been prepared for the protection of human health in the event concentrations of methane exceed allowable limits as required under 30 TAC §330.371. The action plan will address methane level exceedance measurements for both buildings and perimeter monitoring probes.

Emergency Action

As defined in Section 3.7.1.1, the first action in the event that methane is detected at levels above regulatory limits is to protect human health. The following actions will be taken to protect human health dependent on the exceedance location.

Permit Boundary

If methane levels are detected above the regulatory limit in one of the GMPs, the landfill manager will be notified. The immediate emergency response measure will be for the landfill manager to determine if any nearby buildings or structures (including offsite) are at risk and if evacuation of the buildings or structures should be requested.

Structures

If methane concentration exceeded allowable limits within structures, the building will be immediate evacuated and ventilated by opening doors and windows and placing a portable blower to blow clean air into the building. The landfill manager will be notified of the exceedance, and personnel will not be allowed to reenter the building until additional measurements are taken.

Verification Procedures

Once emergency action measures have been taken to protect human health, the landfill manager will require monitoring personnel to begin verification procedures. Verification procedures are intended to determine if the methane levels detected are accurate, or if erroneous levels have been detected.

Permit Boundary

Verification of the detected methane levels above regulatory limits in the GMPs will be conducted within 24 hours using the following procedures:

- Recalibrate gas detection equipment according to manufacturer's recommendations;
- After recalibration of the gas detection equipment, recheck the methane concentration in the GMP; and
- Recheck the methane concentration again within 7 days of the initial reading.

If the measured concentrations of methane are not above regulatory limits in the verification procedure, routine monitoring procedures will resume.

If the follow-up readings suggest that there are methane gas levels exceeding the regulatory limits, notification and remediate procedures must be implemented as described in Section 3.7.6.2 and Section 3.7.7.

Structures

Verification of detected methane levels in the facility structures shall be conducted within 24 hours of the exceedance by monitoring methane levels throughout the structure using a portable gas meter. Readings will be taken in each room and in any confined spaces. If any natural gas appliances exist in the structure, they should be checked for leaks.

If concentrations of methane above the regulatory limit are not detected, personnel may return to the structure. Daily follow-up verification readings must be made for a period of one week after the exceedance measurement. If the follow-up readings suggest that there are methane gas levels exceeding the regulatory limits, notification and remediate procedures must be implemented as described in Section 3.7.6.2 and Section 3.7.7.

3.7.6.2 Notification Procedures

When methane concentrations are detected above the regulatory limit, notification will be made immediately in accordance with §330.371. Within seven days from the date of an initial reading above allowable limits, the owner shall place in the Site Operating Record:

- Concentration of methane gas levels detected as well as time, date, and location;
- Description of steps taken to protect human health; and
- Information regarding the notifications to the Executive Director, local and county officials, emergency officials, and the public of the exceedance;

Within 60 days, the City shall take the following actions:

- Submit and implement a remediation plan for the methane gas releases that describes the nature and extent of gas migration and proposed remedy to the Executive Director; and
- Provide notification to the Executive Director that the remediation plan has been implemented.
- Place a copy of the remediation plan in the Site Operating Record.

3.7.7 Remediation Plan

If verification procedures confirm that the methane levels detected are above the regulatory limits in either an onsite structure or GMP, remediation actions shall be implemented within 60 days of detection. The initial remediation action will be an investigation of the cause of the exceeding methane levels. The investigation will be completed using all or part of the following items:

- Additional gas sampling at the landfill to determine concentrations of methane;

- Soil gas sampling to determine the extent of gas migration beyond the permitted landfill facility;
- Additional or increased GMP monitoring in the area of exceedance;
- Installation of additional GMPs or PVs in the area of exceedance; and
- Installation/expansion of an active LFG collection and control system.

Based on the results of the investigation, the Landfill will determine the appropriate course of action to ensure future methane concentration levels are below regulatory standards. In accordance with 30 TAC §330.371, a remediation plan describing the nature and extent of the problem and the proposed remedy will be submitted to the Executive Director within 60 days of detection that notifies the Executive Director of the plan and that the plan has been implemented. Copies of the remediation plan will be kept in the Site Operation Record. If the remediation plan includes any changes to the LFG Management Plan, approval will be received from the TCEQ prior to implementation.

3.7.8 Backup Plan

This backup plan will be applicable under the assumption that the active GCCS is required to be installed under NSPS and has been developed in accordance with 30 TAC §330.371(g)(3). In the event that the GMCS/GCCS breaks down, the backup plan will be to repair the GMCS/GCCS as soon as possible, dependent on weather, contractor, material, and equipment availability. During the repair period, monitoring frequency on the site GMPs will increase to monitoring levels determined at the time of repair.

3.7.1 Introduction

This landfill gas (LFG) management plan (Plan) has been developed as required by 30 TAC §330.63(g) for the Landfill located in El Paso, Texas. This LFG management plan is consistent with the requirements set forth in 30 TAC §330.371 and provides a site-specific approach for completing LFG management. This Plan describes the existing and proposed LFG management system and discusses the operation and monitoring of these systems, including verification of results, notification procedures, and possible remediation activities. Landfill Gas Management Plans developed by ***R.W. Beck, dated April 3, 2009,*** VIVA Environmental, Inc, dated November 27, 2001, and AGRA Earth and Environmental Group, dated April 8, 1994, were used in the development of the following section ***and are included as Appendix 3M, Attachment 4***.

3.7.1.1 Purpose

Compliance with §330.371(a) requires landfills to implement a routine LFG monitoring program to ensure that the following conditions are met:

- Concentrations of methane gas does not exceed 1.25% by volume in facility structures (excluding gas control or recovery system components); and
- Concentrations of methane gas does not exceed 5% by volume in monitoring points, probes, or other matrices at the facility boundary.

The purpose of this plan is to provide guidelines for the management of LFG and to provide guidance if the levels of methane exceed the limits specified above. Pursuant to §330.371(c), if methane levels are exceeded, the owner or operator shall take the following steps:

- Ensure protection of human health, and notify the Executive Director, local and county officials, emergency officials, and the public of the exceedance;
- Within seven days of the detection, operating records shall be updated to reflect the concentration of methane gas levels detected and the steps that were taken to protect human health; and
- Within 60 days of exceedance, a remediation plan shall be implemented to control methane gas releases. Copies of the remediation plan shall be placed in the operating record, provided to the Executive Director, and notification to the Executive Director that the plan has been implemented. The remediation plan shall include the nature and extent of the problem and the proposed remedy. After review, the Executive Director may require additional remediation measures.

3.7.1.2 General

In accordance with §330.371(d), the Executive Director may establish alternative schedules for demonstrating compliance with subsections §330.371(b) and §330.371(c).

In accordance with §330.371(e), the LFG monitoring and control program will continue for a period of 30 years after certification of final closure of the facility or until the owner or operator receives written authorization to reduce the program. Authorization to reduce LFG monitoring and control shall be based on demonstration that there is not potential for gas migration beyond the property boundary or into site structures. Demonstration shall be supported by collected data and additional studies, as required.

In accordance with §330.371(f), the LFG monitoring and control system shall be revised as needed to maintain current and effective LFG monitoring and control. Post-closure shall not interfere with the function of the LFG monitoring and control systems. Any underground utility trenches that cross the facility boundary shall be vented and monitored regularly.

3.7.2 Site Characteristics

In accordance with §330.371(b), the Landfill shall implement a routine LFG monitoring program to ensure the standards of §330.371(a) are met. The type and frequency of monitoring shall be based on the existing site conditions. The minimum frequency of monitoring shall be quarterly.

3.7.2.1 Soil Conditions

The site geologic conditions present at the Landfill are discussed in Appendix 3K - Geology.

3.7.2.2 Hydrogeologic Conditions

The hydrogeologic conditions present at the Landfill are discussed in Appendix 3K – Geology.

3.7.2.3 Hydraulic Conditions

Hydraulic conditions at the Landfill are discussed in Section 3.3 – Facility Surface Water Drainage Report.

3.7.2.4 Facility Structures within the Property Boundary

The Landfill has a permit boundary of approximately 327-acres of which 277-acres will be available for waste placement. The existing structures located within the property boundary include the existing gatehouse (fee collection building), the maintenance building and a small storage building. The scale house building shall be monitored quarterly with a hand held gas meter at the base of each exterior wall and

ambient air. As part of the facility expansion, it is anticipated that a new equipment maintenance building and scale house will be constructed to the south of the existing buildings outside of the property boundary (Drawing P3-17 in Appendix 3E).

3.7.2.5 Underground Utilities

Underground utility lines that exist within the future disposal footprint of the landfill will be removed prior to the landfill expansion. No utility lines exist within the current disposal footprint of the landfill. Overhead lines provide electricity and telephone service to the buildings on-site. Consequently, monitoring or reporting of easement for buried utilities is not applicable.

3.7.2.6 Offsite Structures

As stated previously, as part of the facility expansion, it is anticipated that a new equipment maintenance building and scale house will be constructed to the south of the existing buildings outside of the property boundary (Drawing P3-17 in Appendix 3E). Any new landfill structures will be monitored similarly to the existing structures located within the property boundary.

In accordance with §330.371(h), since off-site habitable structures are located within 3,000 feet of the waste placement boundary, a permanent perimeter monitoring system is installed at the Landfill and is discussed in more detail below.

3.7.3 Existing Monitoring System

The existing LFG systems consists of gas monitoring probes (GMP) located along the perimeter of the landfill property as well as a landfill gas migration control system (GMCS) located along the western perimeter of the Landfill. The existing systems are shown on Drawing P3-43 in Appendix 3M and are described in further detail below.

3.7.3.1 Gas Monitoring Probes

GMP-1 through GMP-8 were installed in 1994. Description of the installation practices and sample boring and well installation logs are provide in the Landfill Gas Management Plan prepared by AGRA Earth & Environmental Group (AGRA) on April 8, 1994.

GMP-9 through GMP-17 were installed in 2001 by VIVA Environmental, Inc. (VIVA). Description of the installation practices, boring logs and well installation logs are provide in the Landfill Gas Management Plan prepared by VIVA on November 27, 2001.

In 2003, GMP-3 was replaced with GMP-3A and GMP-3 was decommissioned, plugged and abandoned. GMP-3A was installed adjacent to GMP-3 at a depth of approximately 67 feet below ground surface (bgs). The City also decommissioned, plugged and abandoned GMP-4, GMP-5, and GMP-6 based on previous TCEQ approval due to the GMPs no longer falling on the outside perimeter of the landfill. The GMPs were abandoned in November 2003.

In 2004, GMP-18 and GMP-19 were installed to eventually replace GMP-2 and GMP-3A, respectively. The current locations of GMP-2 and GMP-3A are too close to the waste limits, and the locations of GMP-18 and GMP-19 are more suitable for gas monitoring at these two locations. GMP-2 and GMP-3A readings have returned to compliance due to the installation and operation of the active GMCS along a portion of the western perimeter as part of the gas migration remediation plan, but the GMPs have yet to be decommissioned, plugged and abandoned.

Temporary gas monitoring probes GMP-20, GMP-21, and GMP-22 were installed in 2006 to provide additional information on gas migration. Readings taken from the temporary probes have demonstrated that the gas migration issue has been mitigated. These probes are to be decommissioned, plugged and abandoned at a future date.

Boring and well installation logs for GMP-18 through GMP-22 are provided in the Landfill Gas Management Plan prepared by R.W. Beck in 2009.

The permanent Site Methane Monitoring Network currently consists of fourteen (14) GMPs (GMP-1 and GMP-7 through GMP-19) spaced approximately 1,000 feet apart. The GMPs were installed along the permitted area and property boundary. A review of on-site geological/soil data revealed little evidence of any laterally extensive stratographic units which could significantly influence migration of any gases produced within the landfill cells (AGRA, 1994). Additionally, geomembrane liner systems that will exist in future landfill cells should minimize potential for LFG migration away from the landfill footprint.

3.7.3.2 Passive Gas Vents

In June 2000, two passive venting wells (PV-1 and PV-2) were installed in order to intercept and vent methane gas prior to reaching GMP-2 and GMP-3. Both venting wells were installed to a depth of approximately 60-feet bgs in order to capture methane gas at depths where the majority of the elevated methane gas levels were detected and may be generated. In 2001, one vertical passive venting well (PV-3) was installed to a depth of 55-feet below grade.

In November of 2003, PV-1A and PV-2A were constructed to help mitigate the high methane readings recorded in GMP-2 and GMP-3. PV-1, PV-1A and PV-2A still exist within in the LFG management system; however, these wells were capped during the installation of the GMCS.

Five additional passive gas vents were installed in 2006 to provide additional gas venting in the area between GMP-2 and GMP-3. PV-3R was a replacement vent of PV-3 installed in 2001. PV-3 was abandoned in November 2003 as it falls within the landfill footprint and was no longer required to reduce methane levels measured at GMP-4.

PV-2 through PV-7 were converted into active gas extraction wells as part of the GMCS construction. The GMCS system is described in more detail in Section 3.7.3.3 below.

It should be noted that existing PVs (capped and active) will likely be decommissioned, plugged and abandoned prior to the vertical expansion on top of the

existing landfill, assuming that this section of the existing landfill is no longer producing significant amounts of LFG at that time. However, in the event that the PVs still contain a significant amount of LFG, the PVs will be piped horizontally to the landfill perimeter for LFG venting/collection. PVs will not be extended vertically through the future expansion landfill geomembrane liner.

The locations of all active and abandoned GMPs and PVs are shown on Drawing P3-42 in Appendix 3M. Table 3.7-1 provides the approximate coordinates, elevations, and installed depths below ground surface at the time of installation of the GMPs and PVs of the existing system.

Table 3.7-1
Existing LFG Monitoring System Monitoring Points

Reference Point	Date Installed	Northing[1]	Easting[1]	Depth Below Ground Surface	Ground Elevation
GMP-1	1994	10738395.3	413850.0	55-feet	4086.41[2]

PV-4	2006	10740279.1	414045.0	60-feet	4102.00[1]
PV-5	2006	10740094.4	414034.1	60-feet	4101.72[1]
PV-6	2006	10739890.3	414088.3	60-feet	4101.50[1]
PV-7	2006	10739641.6	414044.0	60-feet	4090.41[1]

[1] Northing and Easting locations and ground elevations provided are approximate and based on existing conditions locations and 2011 surveyed contours.
[2] Elevations obtained from VIVA, 2001.

3.7.3.3 Gas Migration Control System (Western Perimeter)

Existing gas monitoring probes (GMP-2, GMP-3, GMP-20, and GMP-21) located along the western perimeter of the Landfill have had periodic elevated methane readings above the regulatory limit of 5%. The Landfill was placed under enforcement action by the TCEQ to mitigate the affected GMPs due to the elevated methane readings.

In an attempt to reduce the methane readings, PV-1A and PV-2A were installed in 2003 and PV-3R through PV-7 were installed in 2006 along the western waste limit of the Landfill; however, the passive vents installed were not effective in controlling gas migration toward the affected GMPs. As a result, the City decided to install an active gas migration control system (GMCS) as part of the site gas remediation plan.

The GMCS is an active extraction system to control LFG migration in the affected area. The system is a partial active system, because it was installed only along a distance of approximately 1,000 feet over the northwestern portion of the unlined landfill. Existing PV-2 through PV-7 were converted into active gas extraction wells as part of the GMCS. In addition to the 6 converted extraction wells, the GMCS consists of LFG header and lateral pipes, a condensate sump and pump system, a blower/flare station, a condensate storage tank, and an air compressor system to power the condensate pump system. Since the GMCS system installation and subsequent start up in August of 2009, the GMP readings have been in compliance. If there are methane readings out of compliance in the future, further investigation will be conducted to ensure that the existing system is performing optimally. In the case that the system is running at peak performance and methane readings are still out of compliance, additional PVs may be added to the GMCS network. GMCS details are provided in the R.W. Beck Landfill Gas Management Plan of 2009.

3.7.4 Proposed LFG Management System

3.7.4.1 NSPS Requirements

Pursuant to 40 CFR Part 60, Subpart Cc §60.33c, "a State plan shall include control of MSW landfill emissions at each MSW landfill meeting the following three conditions:

1. The landfill has accepted waste at any time since November 8, 1987, or has additional design capacity available for future waste deposition;
2. The landfill has a design capacity greater than or equal to 2.5 million megagrams and 2.5 million cubic meters. The landfill may calculate design capacity in either megagrams or cubic meters for comparison with the exemption values. Any density conversions shall be documented and submitted with the design capacity report; and,
3. The landfill has a nonmethane organic compound emission rate of 50 megagrams per year or more."

Design Capacity

One threshold for NSPS requirements is the Landfill having a design capacity of 2.5 million megagrams (Mg) or cubic meters. The Landfill design capacity is over the NSPS threshold of 2.5 million Mg.

NMOCs

Because the Landfill is over the design capacity threshold, nonmethane organic compound (NMOC) monitoring is required at a Tier II level. The last NMOC monitoring event conducted at the Landfill was completed in March 2007. The results from the NMOC monitoring indicate that the maximum NMOC concentration will occur in year 2047 at a concentration of 34.69 Mg (under the 50 Mg threshold). According to the 2007 test results, the Landfill is currently under the annual air emissions threshold of the Federal New Source Performance Standards (NSPS), and as a result, there is no present requirement for the City to install a LFG collection and control system (GCCS) covering the entire landfill. The latest NMOC results are provided in Appendix 3M.

NMOC monitoring will ***continue, as necessary, in accordance with the site air permit*** ~~continue on a 5-year increment bases (next monitoring event scheduled in 2012)~~ and the Landfill will continue to evaluate the need for an active GCCS based on future NMOC monitoring results.

3.7.4.2 Active Gas Collection and Control System

Although the Landfill is currently not required to install an active GCCS system, the following system has been designed with the assumption that the Landfill will either eventually have to comply with NSPS standards, or will choose to install an active GCCS voluntarily to further landfill gas to energy efforts.

The designed active GCCS will consist of a series of wells and piping used to convey LFG to an open flare station for combustion or to a landfill-gas-to-energy conversion system. The GCCS will be constructed in a similar manner to the GMCS and may include some of the same components as the GMCS. GCCS components will include:

- Header/Manifold ~~– Loop of HDPE surface piping around the Landfill footprint connecting all lateral piping branches.~~
- Lateral ~~– HDPE surface piping connecting a vertical gas well to the manifold.~~
- Vertical Gas Wells (GW) ~~– Vertical gas wells will be constructed using three foot diameter borings with a 6-inch Schedule 80 (SCH 80) CPVC perforated casing extending from 10 feet bgs to within 15 feet of the leachate collection system. Each GW will have a wellhead capable of measuring and controlling LFG flow. Gas flow from the well will be controlled using a PVC gate valve. Immediately downstream of the flow control valve will be a sample port for monitoring gas quality and vacuum at the well. The end of the wellhead will be connected to the lateral surface piping. A typical GW schematic is provided on Drawing P3-41 in Appendix 3M.~~

- Cleanout Stations~~ – Access points for manual vactoring and jet flushing for removal of debris or condensate from the headers. The cleanout stations will be located periodically to provide access to the entire length of manifold.~~
- Condensate Sumps~~ – Condensate accumulators which will contain a pump and float switch system to pump condensate back to the leachate collection system.~~
- Flare Station~~ Components~~

  ~~1. Knockout vessel to further remove condensate with a return line to a condensate sump.~~

  ~~2. Blower(s) to maintain vacuum on the collection network.~~

  ~~3. Flow meter to measure instantaneous flow and record cumulative flow.~~

  ~~4. An Automatic shut-off to prevent LFG flow in either direction in the event of system shutdown.~~

  ~~5. A utility flare for combustion of all LFG collected by the GCCS.~~

As shown on Drawing P3-39 in Appendix 3M, the GWs were designed at a radius of influence (ROI) of 150-feet. The ROI was developed based on previous experience with similar type soils (silty sand/sandy) and drier waste moisture content. The actual location of the GWs may vary dependent on site conditions at the time of installation.

3.7.4.3 Existing System Modifications

Upon Landfill expansion, it is anticipated that GMP-7 will be removed from the monitoring system and that GMP-23 will replace GMP-7 in the monitoring network ***(Drawing P3-43 in Appendix 3M)***. GMP-23 will be located on the outside of the Landfill limits, but inside the property boundary. GMP-7 will be decommissioned, plugged and abandoned upon installation of GMP-23. GMP-23 will be installed following the guidelines set forth in Section 4.2 of the AGRA Landfill Gas Monitoring Plan, 1994 ***(Appendix 3M, Attachment 4)***.

3.7.5 Monitoring Plan

3.7.5.1 Perimeter Monitoring

Perimeter Monitoring Network

The LFG monitoring probe network at the Landfill includes a total of fourteen existing LFG monitoring probes (GMP-1 and GMP-7 through GMP-19) located along the perimeter of the waste fill area. Locations of the existing GMPs are shown on Drawing P3-43 in Appendix 3M. As mentioned previously, GMP-7 will be replaced with GMP-23 in the permanent monitoring network.

Landfill Gas Monitoring Probes

LFG monitoring probes have been installed along the perimeter of the waste fill area. Boring logs and typical construction details for the GMPs have been provided in

previous versions of the LFG Management Plan (R.W. Beck 2009, VIVA 2001, AGRA 1994) ***which are provided in Appendix 3M, Attachment 4***. Future LFG monitoring probes will be installed in accordance with the detail shown on Drawing P3-44 in Appendix 3M.

Monitoring Procedures

During each monitoring event, the GMPs will be monitored for the following parameters:

- Probe gas pressure at each probe;
- Methane gas concentrations at each probe;
- Barometric pressure during the monitoring event; and
- Ambient temperature during the monitoring event.

Monitoring for gas composition and pressure will be performed using a portable combustible gas indicator capable of measuring the above parameters. Prior to the start of monitoring, the tester shall calibrate monitoring instruments in accordance with the manufacturer's specifications. The instrument is factory calibrated semi-annually. The tester should also record time, temperature, barometric pressure, and weather conditions prior to the start of the monitoring period. Each GMP shall be monitored using the following monitoring procedures:

- Check GMP's integrity;
- Determine pressure within sealed monitoring tube;
- Determine methane concentrations at each location; and
- Record all data on the LFG Monitoring Report Form (Appendix 3M).

Maintenance Procedures

Each time LFG monitoring is conducted, the sampler will inspect the integrity of the LFG monitoring probes. The sampler will record pertinent information on the LFG Monitoring Report Form provided in Appendix 3M. The LFG Monitoring Report Form will be kept in the Site Operating Record. The sampler will perform the following at each monitoring event:

- Verify that the GMP identification number is clearly labeled on the outer casing or lid;
- Verify that the protective casing is intact and is not bent or excessively corroded;
- Verify that the protective barrier pipes are intact;
- Verify that the working pad is intact;
- Verify that the lock is functional;
- Verify that the hinged cover is in working order; and
- Verify that the inner casing is intact.

If damage or excessive wear to the LFG monitoring probe is observed, it will be reported to the landfill manager and repaired within 30 days of the date damage is observed. If it is not possible to repair the GMP, the LFG monitoring probe will be decommissioned and replaced within 60 days from the TCEQ approval date of the permit modification requesting replacement of the GMP. Upon completion of the replacement GMP, an as-built documentation report including boring and well installation logs will be submitted to the TCEQ.

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.2 GMCS/GCCS Monitoring

GMCS Monitoring Network

The gas migration control system network currently consists of 6 active gas wells that were converted from passive gas vents (PV-2 to PV-7). The system was installed to mitigate methane exceedance detected in GMP-2, GMP-3, GMP-20 and GMP-21 along the western perimeter of the unlined landfill area. In the event that the levels of methane increase above regulatory standards in the affected GMPs, expansion of the existing GMCS may occur. It is anticipated that this system will eventually be replaced by the GCCS network.

GCCS Monitoring Network

The GCCS is anticipated to be installed either upon the landfill reaching NSPS standards requirements or on a voluntary basis. This is dependent both on the current permitted waste capacity (which the landfill is currently exceeding the limits of 2.5 million megagrams or 2.5 million cubic meters) and the current NMOC concentration within the LFG. As described in Section 3.7.4.1, the actual timing for the Landfill reaching NSPS standards is currently unknown and will be dependent on future NMOC monitoring.

Monitoring Procedures

The GMCS and GCCS are designed to collect LFG and prevent fugitive emissions from the Landfill. Since the rate of LFG production within the landfill varies, the amount of gas withdrawn by the GMCS/GCCS GWs should also be adjusted. During each monitoring event, the Flare (and/or potential gas-to-energy conversion system) will be monitored and the GWs will likely be monitored for the following parameters:

- Gas flow at each location;
- Gas pressure at each location;
- Gas temperature at each location;
- Methane gas concentrations at each location;
- Oxygen gas concentrations at each location;
- Barometric pressure during the monitoring event; and
- Ambient temperature during the monitoring event.

Monitoring for gas composition, pressure, and temperature will be performed using a portable combustible gas indicator capable of measuring the above parameters. Prior to the start of monitoring, the tester shall calibrate monitoring instruments in accordance with the manufacturer's specifications. The GMCS/GCCS will likely be sampled using the following sampling procedure:

- Record date, time and current weather conditions;
- Record initial data from Flare skid;
- Perform GW maintenance check at each GW;
- Record above parameters at each GW;
- Adjust flow through the wellhead at each GW based on the methane and oxygen measurements (if necessary); and
- Record end data from Flare skid.

Maintenance Procedures

When the GCMS/GCCS monitoring includes the monitoring of the GWs, the sampler will inspect the integrity of the GWs. The sampler will record pertinent information on the LFG Monitoring Report Form which will be placed in the Site Operating Record. The sampler will also observe the wellhead during the monitoring event to ensure no damage has occurred to the wellhead. If damage or excessive wear to the GW or wellhead is observed, it will be reported to the landfill manager and repaired within 30 days of the date damage is observed. If it is not possible to repair the GW, the Landfill will evaluate the effectiveness of replacing the GW within the gas collection system. If the GW is replaced, an as-built documentation report will be submitted to the TCEQ including boring and well installation logs.

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.3 Facility Structures Monitoring

Monitoring Procedures

On-site buildings and structures designed for human occupation will be monitored, at a minimum, quarterly with a portable combustible gas indicator. The buildings shall be monitored quarterly with a hand held gas meter at the base of each exterior wall and also the ambient air.

If methane concentration exceeded allowable limits within structures, the building will be immediate evacuated and ventilated by opening doors and windows and placing a portable blower to blow clean air into the building. Notification consistent with the procedures outlined in Section 3.7.6.2 will be implemented immediately.

Maintenance Procedures

The combustible gas monitoring instrument will be calibrated and maintained in accordance with the manufacturer's instructions.

3.7.5.4 Recordkeeping/Reporting

Field monitoring data records will be placed in the Site Operating Record and maintained onsite for inspection. Field data will be recorded on the LFG Monitoring Report Form provided in Appendix 3M.

3.7.5.5 Monitoring Frequency

LFG monitoring probes and facility structures will be monitored quarterly at a minimum. The facility will monitor the locations more frequently if monitoring results indicate that LFG migration is occurring or is accumulating in the structures.

GMCS monitoring is required on a monthly basis; however, Landfill personnel typically monitor on a weekly basis. GCCS monitoring will occur similarly to the GMCS monitoring and shall comply with 40 CFR Part 60, Subpart WWW §60.756.

3.7.6 Action Plan

3.7.6.1 Initial Response Measures

This action plan has been prepared for the protection of human health in the event concentrations of methane exceed allowable limits as required under 30 TAC §330.371. The action plan will address methane level exceedance measurements for both buildings and perimeter monitoring probes.

Emergency Action

As defined in Section 3.7.1.1, the first action in the event that methane is detected at levels above regulatory limits is to protect human health. The following actions will be taken to protect human health dependent on the exceedance location.

Permit Boundary

If methane levels are detected above the regulatory limit in one of the GMPs, the landfill manager will be notified. The immediate emergency response measure will be for the landfill manager to determine if any nearby buildings or structures (including offsite) are at risk and if ***evacuation*** ~~excavation~~ of the buildings or structures should be requested.

Structures

If methane concentration exceeded allowable limits within structures, the building will be immediate evacuated and ventilated by opening doors and windows and placing a portable blower to blow clean air into the building. The landfill manager will be notified of the exceedance, and personnel will not be allowed to reenter the building until additional measurements are taken.

Verification Procedures

Once emergency action measures have been taken to protect human health, the landfill manager will require monitoring personnel to begin verification procedures.

Verification procedures are intended to determine if the methane levels detected are accurate, or if erroneous levels have been detected.

Permit Boundary

Verification of the detected methane levels above regulatory limits in the GMPs will be conducted within 24 hours using the following procedures:

- Recalibrate gas detection equipment according to manufacturer's recommendations;
- After recalibration of the gas detection equipment, recheck the methane concentration in the GMP; and
- Recheck the methane concentration again within 7 days of the initial reading.

If the measured concentrations of methane are not above regulatory limits in the verification procedure, routine monitoring procedures will resume.

If the follow-up readings suggest that there are methane gas levels exceeding the regulatory limits, notification and remediate procedures must be implemented as described in Section 3.7.6.2 and Section 3.7.7.

Structures

Verification of detected methane levels in the facility structures shall be conducted within 24 hours of the exceedance by monitoring methane levels throughout the structure using a portable gas meter. Readings will be taken in each room and in any confined spaces. If any natural gas appliances exist in the structure, they should be checked for leaks.

If concentrations of methane above the regulatory limit are not detected, personnel may return to the structure. Daily follow-up verification readings must be made for a period of one week after the exceedance measurement. If the follow-up readings suggest that there are methane gas levels exceeding the regulatory limits, notification and remediate procedures must be implemented as described in Section 3.7.6.2 and Section 3.7.7.

3.7.6.2 Notification Procedures

When methane concentrations are detected above the regulatory limit, notification will be made immediately in accordance with §330.371. Within seven days from the date of an initial reading above allowable limits, the owner shall place in the Site Operating Record:

- Concentration of methane gas levels detected as well as time, date, and location;
- Description of steps taken to protect human health; and
- Information regarding the notifications to the Executive Director, local and county officials, emergency officials, and the public of the exceedance;

Within 60 days, the City shall take the following actions:

- Submit and implement a remediation plan for the methane gas releases that describes the nature and extent of gas migration and proposed remedy to the Executive Director; and
- Provide notification to the Executive Director that the remediation plan has been implemented.
- Place a copy of the remediation plan in the Site Operating Record.

3.7.7 Remediation Plan

If verification procedures confirm that the methane levels detected are above the regulatory limits in either an onsite structure or GMP, remediation actions shall be implemented within 60 days of detection. The initial remediation action will be an investigation of the cause of the exceeding methane levels. The investigation will be completed using all or part of the following items:

- Additional gas sampling at the landfill to determine concentrations of methane;
- Soil gas sampling to determine the extent of gas migration beyond the permitted landfill facility;
- Additional or increased GMP monitoring in the area of exceedance;
- Installation of additional GMPs or PVs in the area of exceedance; and
- Installation/expansion of an active LFG collection and control system.

Based on the results of the investigation, the Landfill will determine the appropriate course of action to ensure future methane concentration levels are below regulatory standards. In accordance with 30 TAC §330.371, a remediation plan describing the nature and extent of the problem and the proposed remedy will be submitted to the Executive Director within 60 days of detection that notifies the Executive Director of the plan and that the plan has been implemented. Copies of the remediation plan will be kept in the Site Operation Record. If the remediation plan includes any changes to the LFG Management Plan, approval will be received from the TCEQ prior to implementation.

3.7.8 Backup Plan

This backup plan will be applicable under the assumption that the active GCCS is required to be installed under NSPS and has been developed in accordance with 30 TAC §330.371(g)(3). In the event that the GMCS/GCCS breaks down, the backup plan will be to repair the GMCS/GCCS as soon as possible, dependent on weather, contractor, material, and equipment availability. During the repair period, monitoring frequency on the site GMPs will increase to monitoring levels determined at the time of repair.

The Final Closure Plan has been prepared in compliance with applicable regulations (30 TAC §330.63(h), 330.457, and 330.459) for the McCombs Landfill. Within 180 days of the last receipt of wastes for any MSWLF unit, the owner or operator will complete the installation of a final cover system as permitted, designed and constructed to minimize infiltration and erosion. This final closure plan includes the following:

- A description of the prescriptive final cover design, including methods for installation;
- A description of the alternative final cover design, including justification in accordance with the *Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill,* and methods for installation;
- An estimate of the largest area requiring final cover at any time during the active life of the landfill;
- An estimate of the maximum inventory of wastes on-site over the active life of the landfill; and
- A schedule for completing all final cover activities.

A copy of this closure plan will be included in the site operating record.

The Final Contour Map for the Landfill depicting the final contours, site access roads, top and side slopes, and surface drainage features is located in Appendix 3E - Site Layout Plans.

The estimated cost to hire a third party to perform the closure project can be found in Appendix 3N, Attachment 2 - Closure Cost Estimates.

3.8.1 Description of Final Cover Design

30 TAC §330.457(e)(1)

The final cover will be applied to areas of the Landfill as they reach final contour elevations shown on the Final Cover Plan in Appendix 3G - Construction Design Details, Drawing P3-33. The prescriptive final cover for areas of the Landfill with a synthetic bottom liner consists of a minimum of an eighteen inch infiltration layer over the intermediate and daily cover layers having a coefficient of permeability less than or equal to $1x10^{-5}$ cm/sec. The infiltration layer is then overlain with a synthetic flexible membrane with permeability less than that of the bottom liner system. Twelve inches of earthen material are then placed, providing the erosion layer. On top of the erosion layer, six inches of vegetative layer (or 4 inches of rock layer) is placed that can support and sustain native plan growth. The rock layer, if used instead of the

vegetative layer, would consist of rounded to sub-rounded river rock, crushed angular to sub-angular rock, or a combination of the two.

The synthetic membrane shall be a minimum of 40 mils (LLDPE) to ensure proper seaming. Drawing P3-34 in Appendix 3G - Construction Design Details, shows details for the prescriptive final cover system design for areas of the landfill that have a synthetic bottom liner. Drawing P3-29 in Appendix 3G details the Typical Landfill Perimeter Section, which shows how the liner is anchored to the existing grades.

An alternative final cover system has been designed for the McCombs Landfill. The alternative cover system includes only soil cover as opposed to a synthetic liner. The system will include the 12 inches of preliminary cover (6 inches of daily cover and 6 inches of intermediate cover) as is in the prescriptive cover, a 6-inch support layer, an 18 inch erosion layer, and a 4-inch top layer consisting of rock armor. The alternative final cover is in lieu of the low permeability soil, synthetic membrane liner and topsoil (or rock) described in the prescriptive cover above. Drawing P3-35 in Appendix 3G provides detail on the alternative final cover profile.

Appendix 3N - Closure Details presents a demonstration of the infiltration equivalency of the two final cover system options and justification for the alternative earth cover in accordance with the "*Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill"*.

Appendix 3B, Attachment 5 presents the calculated soil loss for the two final cover system options.

The prescriptive cover sequencing will be different for areas with bottom liner than for those without and both are described below.

3.8.1.2 Sequence of the Final Cover Installation

The following provides a general sequencing plan for the prescriptive final cover system installation for the Landfill areas that include a synthetic bottom liner:

- Apply the final six inches of daily cover, and if not closed within 180 days apply six inches of intermediate cover;
- Place 18 inches of earthen material (with a coefficient of permeability less than or equal to 1 X 10^{-5} cm/sec) that will serve as the infiltration layer;
- Place 40 mil LLDPE geomembrane;
- Place 12 inches of earthen material that will serve as the erosion layer;
- Place the 6 inch minimum earthen vegetative layer that is capable of supporting and sustaining native plant growth (or place 4 inches of crushed rock or river rock armoring in lieu of 6 inch earthen vegetative layer); and
- Refer to Drawing P3-34 - Final Cover Details, in Appendix 3G for details of this final cover system design.

The following provides a general sequencing plan for the prescriptive final cover system installation for the McCombs Landfill areas that do not include a synthetic bottom liner:

- Apply the final six inches of daily cover, and if not closed within 180 days apply six inches of intermediate cover;
- Place 18 inches of earthen material (with a coefficient of permeability less than or equal to 1 X 10^{-5} cm/sec) that will serve as the infiltration layer;
- Place the 6 inch minimum earthen vegetative layer that is capable of supporting and sustaining native plant growth (or place 4 inches of crushed rock or river rock armoring in lieu of 6 inch earthen vegetative layer);
- Refer to Drawing P3-34 in Appendix 3G for details of this final cover system design.

It should be noted that the only area that may receive the prescriptive final cover for areas that do not include a synthetic bottom liner include areas of existing unlined Landfill that will not receive any further waste, the western outside slope of Sector I and the southern outside slope of Sector J. The areas of the slopes for Sectors I and Sectors J are identified on Drawing ***P3-33B*** ~~P3-28~~ in Appendix 3G, Attachment 4. All other areas will either receive the prescriptive final cover system (with bottom liner) or the alternative final cover system described below.

The following provides a general sequencing plan for the alternative final cover system installation for the McCombs Landfill areas (both with and without a synthetic bottom liner:

- Apply the final six inches of daily cover and 6 inches of intermediate cover;
- Apply 6 inches of support soil compacted to 80%;
- Apply 18 inches of erosion soil compacted to 90%;
- Apply 4 inches of top layer consisting of rock armor;
- Refer to Drawing P3-35 - Alternative Cover Details, in Appendix 3G for details of this final cover system design.

3.8.1.3 Site Preparation

Site preparation includes clearing and grubbing vegetation in areas to receive intermediate cover. The intermediate cover will be prepared and graded to meet the criteria set forth in the Final Cover Quality Control Plan. Additional clean fill material from on-site native soil can be used to meet the required contour elevations.

3.8.1.4 Prescriptive Final Cover Construction

Testing and Evaluation of the prescriptive final cover system will be completed in accordance with 30 TAC §330.457(c). For the prescriptive cover, the infiltration material will be placed in accordance with the Final Cover Quality Control Plan (located in Appendix 3P) and will be tested at least once per surface acre for coefficient of permeability. Permeability data will be submitted to the TCEQ executive director. A liquid limit (LL) of not less than 30 and a plasticity index (PI) of not less than 15 are required, but lower values of Atterburg limits may be acceptable.

The remaining layers (membrane, erosion and vegetative or rock layers) will be installed in accordance with the Final Cover Quality Control Plan. If rock is chosen as the final layer, it will be graded to provide an interlocking framework for slope stability and to minimize erosion for surface water.

3.8.1.5 Alternative Final Cover Construction

Testing and Evaluation of the alternative final cover system will be completed in accordance with the TCEQ Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill and findings of the Unsat-H model and report found in Appendix 3N - Closure Details. For the alternative cover, the support layer will be much less dense than the infiltration material utilized in the prescriptive cover. The Interstate Technology and Regulatory Council (ITRC) Alternative Landfill Technologies Team states that a range of 75-85% compaction is best for evapotranspiration monolithic soil final cover systems. This layer will be placed at 80% compaction.

The erosion layer will be installed in accordance to the TCEQ Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill and finding of the Unsat-H model and report found in Appendix 3N. This layer will be placed at 90% compaction.

3.8.1.6 Final Cover Construction Activities for both Prescriptive and Alternative Systems

A gas venting system will be implemented to dissipate the gas produced by anaerobic degradation of the waste at the site. Drawings P3-41 and P3-42, in Appendix 3M - Landfill Gas Management Details, provide landfill gas venting system details. Any gas collection system used at the site will be designed and installed with approval of the TCEQ.

Erosion and soil loss preventative measures and maintenance will be required for the final cover. Calculations using the Revised Universal Soil Loss Equation (RUSLE) for estimating soil loss on the final cover of the landfill can be seen in Appendix 3B, Attachment 5 – Closure Soil Loss Calculations. Refer to Appendix 3G for slope stability analysis.

3.8.2 Largest Area Requiring Final Cover

30 TAC §330.457(e)(2)

The ***largest open*** ~~total final cover~~ area at the McCombs Landfill ***at any given time*** is not expected to exceed approximately 222.8 acres for areas that will ever require final cover. The landfill development plan has been broken into different sections to be constructed over time and therefore smaller sections of the total may be closed individually or collectively as they reach permitted maximum elevations. The largest area of closure is during Sector G development, prior to the closure of Sector F, for which the total open area is 113.2 acres and the incremental closure area is 18.3 acres.

Also included at that time will be 70.8 acres in the existing unlined landfill area and 20.5 acres lined landfill area in the existing Phase I and II areas. The filling sequence is provided in the Appendix 3E - Site Layout Plans.

P3-45 provides the largest open area at any time during site development that will require final cover (222.8-acres). The final cover portrayed is for both the existing and future sector boundary extensions. P3-45 is only applicable at the time of Sector G development (i.e., prior to the development of the piggyback area). It should be noted final cover will not be placed on the existing unlined (70.8 acres) and lined (20.5 acres) areas prior to the piggyback liner unless the Landfill is closed prior to development of the piggyback area (Sectors H-J) and the vertical expansion of Sector K.

3.8.3 Maximum Waste Inventory

30 TAC §330.457(e)(3)

Approximately 5,964,060 cubic yards (cy) of waste (and intermediate cover) have been landfilled in the existing completed phases of the Landfill, as of December 31, 2010.

The total Landfill volume was estimated using AutoCAD by comparing the top of geomembrane to the top of final cover. The total remaining Landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including waste and daily**,** intermediate, and final cover), which provides capacity through 2014 based on table 3H-1 in Appendix 3H-Site Life Projections. The total remaining Landfill volume available for waste disposal including the remainder of Sector A and all subsequent planned sectors (B through K) is ***62,853,182*** ~~62,532,764~~ CY. Given the remaining capacity above, the remaining estimated life of the Landfill is until 2059. The total volume in place at that time will be ***68,817,242*** ~~68,496,824~~ CY.

3.8.4 Closure Schedule

30 TAC §330.457(e)(4), 330.457(f), and 330.457(g)

The McCombs Landfill will be efficiently closed by the following procedure:

- The Owner/Operator will provide written notification to the TCEQ within 45 days prior to beginning final closure activities stating their intent to close a section of the facility or the entire facility site. This notice will also be placed in the operating record.
- The Owner/Operator will publish a public notice of final closure in the largest circulating newspaper in the facility area within 90 days prior to beginning final closure activities of the entire facility site. This notice will include name, address, location of the facility, permit number, and date of final receipt of waste. Copies of the final closure plan will be made available for the public to review.

- At least one sign will be posted at the main entrance (and others where appropriate around the site perimeter) following the closure date notifying readers of the final date of closure.
- Barriers shall be installed at all entrances, gates, or access points to the Landfill following closure in order to prevent unauthorized dumping of solid waste.
- Final closure for the entire facility site shall begin no later than 30 days after the date on which the Landfill receives final waste. If the Landfill has remaining capacity and will likely continue to receive additional waste then final closure will continue no later than one year after receipt of final waste. If time beyond the one year is necessary, a request for extension may be submitted to the executive director for review and approval. The request must include documentation demonstrating the site had capacity to receive additional waste and that the owner/operator has taken steps and will continue to take steps to prevent threats to human health and environment from the unclosed portions of the site.
- The Final closure in accordance with this plan shall be completed within 180 of initiation of final closure activities. If it is likely to take beyond 180 days, an extension can be requested in writing to the executive director. The request must include all documentation demonstrating that closure will take longer than 180 days and that the owner/operator has taken steps and will continue to take steps to prevent threats to human health and environment from the unclosed portions of the site.
- Documented certification by an independent licensed Professional Engineer will be submitted to the TCEQ following completion of final closure certifying completion in accordance with the final closure plan and including all documentation necessary for certification of final closure. A copy of the approved certification from the TCEQ will be placed in the operating record.
- Within 10 days of final completion of closure activities for the Landfill, the owner/operator will submit a certified copy of an Affidavit to the Public to the Executive Director. A copy will also be placed in the operating record. The affidavit will include an updated metes and bounds description of the extent of the disposal areas.
- A certified notation will be recorded on the deed to the property the facility is on that will in perpetuity notify a potential purchaser that the land has previously been used as a landfill. The use of this land will be restricted to the provisions specified in Section 3.9 - Post-Closure Plan. The owner/operator will submit a certified copy of the modified deed to the Executive Director and place a copy in the site operating record within 10 days of final completion of closure activities for the Landfill.

3.8.5 Final Contour Map

30 TAC §330.457(e)(5)

A final contour map depicting the final contours, 100-year floodplain, and establishing top slopes and sideslopes for the McCombs Landfill is provided in Appendix 3E - Site

Layout Plan, Drawing P3-16. No structural designs for collection and conveyance along the top and side slopes (i.e., berms, dikes, chutes) are recommended as the final cover design meets the requirements for soil loss and non-erodible velocities.

3.8.6 Final Closure Costs

30 TAC §330.503

The estimated cost to hire a third party to perform the closure project (for the largest area to ever require final cover, identified in section 3.3.2) can be found in Appendix 3N, Attachment 3 - Closure Cost Estimates.

Additionally, in order to comply with 30 TAC §330.503(b), a copy of the City's current financial assurance cost estimates for the facility are provided in Appendix 3N, Attachment 3.

The Final Closure Plan has been prepared in compliance with applicable regulations (30 TAC §330.63(h), 330.457, and 330.459) for the McCombs Landfill. Within 180 days of the last receipt of wastes for any MSWLF unit, the owner or operator will complete the installation of a final cover system as permitted, designed and constructed to minimize infiltration and erosion. This final closure plan includes the following:

- A description of the prescriptive final cover design, including methods for installation;
- A description of the alternative final cover design, including justification in accordance with the *Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill,* and methods for installation;
- An estimate of the largest area requiring final cover at any time during the active life of the landfill;
- An estimate of the maximum inventory of wastes on-site over the active life of the landfill; and
- A schedule for completing all final cover activities.

A copy of this closure plan will be included in the site operating record.

The Final Contour Map for the Landfill depicting the ~~proposed~~ final contours, site access roads, top and side slopes, and ~~proposed~~ surface drainage features is located in Appendix 3E - Site Layout Plans.

The estimated cost to hire a third party to perform the closure project can be found in Appendix 3N, Attachment 2 - Closure Cost Estimates.

3.8.1 Description of Final Cover Design

30 TAC §330.457(e)(1)

The final cover will be applied to areas of the Landfill as they reach final contour elevations shown on the Final Cover Plan in Appendix 3G - Construction Design Details, Drawing P3-33. The prescriptive final cover for areas of the Landfill with a synthetic bottom liner consists of a minimum of an eighteen inch infiltration layer over the intermediate and daily cover layers having a coefficient of permeability less than or equal to $1x10^{-5}$ cm/sec. The infiltration layer is then overlain with a synthetic flexible membrane with permeability less than that of the bottom liner system. Twelve inches of earthen material are then placed, providing the erosion layer. On top of the erosion layer, six inches of vegetative layer (or 4 inches of rock layer) is placed that can support and sustain native plan growth. The rock layer, if used instead of the

vegetative layer, would consist of rounded to sub-rounded river rock, crushed angular to sub-angular rock, or a combination of the two.

The synthetic membrane shall be a minimum of 40 mils (LLDPE) to ensure proper seaming. Drawing P3-34 in Appendix 3G - Construction Design Details, shows details for the prescriptive final cover system design for areas of the landfill that have a synthetic bottom liner. Drawing P3-29 in Appendix 3G details the Typical Landfill Perimeter Section, which shows how the liner is anchored to the existing grades.

~~The City of El Paso is proposing an~~ ***An*** alternative final cover system ***has been designed*** ~~option~~ for the McCombs Landfill. The alternative cover system includes only soil cover as opposed to a synthetic liner. The system will include the 12 inches of preliminary cover (6 inches of daily cover and 6 inches of intermediate cover) as is in the prescriptive cover, ***a 6*** ~~12~~ inch~~es of vegetative~~ support ***layer,*** ~~soil and~~ ***an 18*** ~~12~~ inch~~es of vegetative topsoil~~ ***erosion layer, and a 4-inch top layer consisting of rock armor***. The ~~24"~~ alternative final cover is in lieu of the low permeability soil, synthetic membrane liner and topsoil (or rock) described in the prescriptive cover above. Drawing P3-35 in Appendix 3G provides detail on the alternative final cover profile.

Appendix 3N - Closure Details presents a demonstration of the infiltration equivalency of the two final cover system options and justification for the alternative earth cover in accordance with the "*Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill"*.

Appendix 3B, Attachment 5 presents the calculated soil loss for the two final cover system options.

The prescriptive cover sequencing will be different for areas with bottom liner than for those without and both are described below.

3.8.1.2 Sequence of the Final Cover Installation

The following provides a general sequencing plan for the prescriptive final cover system installation for the Landfill areas that include a synthetic bottom liner:

- Apply the final six inches of daily cover, and if not closed within 180 days apply six inches of intermediate cover;
- Place 18 inches of earthen material (with a coefficient of permeability less than or equal to 1 X 10^{-5} cm/sec) that will serve as the infiltration layer;
- Place 40 mil LLDPE geomembrane;
- Place 12 inches of earthen material that will serve as the erosion layer;
- Place the 6 inch minimum earthen vegetative layer that is capable of supporting and sustaining native plant growth (or place 4 inches of crushed rock or river rock armoring in lieu of 6 inch earthen vegetative layer); and
- Refer to Drawing P3-34 - Final Cover Details, in Appendix 3G for details of this final cover system design.

The following provides a general sequencing plan for the prescriptive final cover system installation for the McCombs Landfill areas that do not include a synthetic bottom liner:

- Apply the final six inches of daily cover, and if not closed within 180 days apply six inches of intermediate cover;
- Place 18 inches of earthen material (with a coefficient of permeability less than or equal to 1 X 10^{-5} cm/sec) that will serve as the infiltration layer;
- Place the 6 inch minimum earthen vegetative layer that is capable of supporting and sustaining native plant growth (or place 4 inches of crushed rock or river rock armoring in lieu of 6 inch earthen vegetative layer);
- Refer to Drawing P3-34 in Appendix 3G for details of this final cover system design.

It should be noted that the only area that may receive the prescriptive final cover for areas that do not include a synthetic bottom liner include areas of existing unlined Landfill that will not receive any further waste, the western outside slope of Sector I and the southern outside slope of Sector J. The areas of the slopes for Sectors I and Sectors J are identified on Drawing P3-28 in Appendix 3G, Attachment 4. All other areas will either receive the prescriptive final cover system (with bottom liner) or the alternative final cover system described below.

The following provides a general sequencing plan for the alternative final cover system installation for the McCombs Landfill areas (both with and without a synthetic bottom liner:

- Apply the final six inches of daily cover and 6 inches of intermediate cover;
- Apply 6 inches of support soil compacted to 80%;
- Apply 18 inches of erosion soil compacted to 90%;
- Apply 4 inches of top layer consisting of rock armor;
- Refer to Drawing P3-35 - ~~Proposed~~ Alternative Cover Details, in Appendix 3G for details of this final cover system design.

3.8.1.3 Site Preparation

Site preparation includes clearing and grubbing vegetation in areas to receive intermediate cover. The intermediate cover will be prepared and graded to meet the criteria set forth in the Final Cover Quality Control Plan. Additional clean fill material from on-site native soil can be used to meet the required contour elevations.

3.8.1.4 Prescriptive Final Cover Construction

Testing and Evaluation of the prescriptive final cover system will be completed in accordance with 30 TAC §330.457(c). For the prescriptive cover, the infiltration material will be placed in accordance with the Final Cover Quality Control Plan (located in Appendix 3P) and will be tested at least once per surface acre for

coefficient of permeability. Permeability data will be submitted to the TCEQ executive director. A liquid limit (LL) of not less than 30 and a plasticity index (PI) of not less than 15 are required, but lower values of Atterburg limits may be acceptable.

The remaining layers (membrane, erosion and vegetative or rock layers) will be installed in accordance with the Final Cover Quality Control Plan. If rock is chosen as the final layer, it will be graded to provide an interlocking framework for slope stability and to minimize erosion for surface water.

3.8.1.5 Alternative Final Cover Construction

Testing and Evaluation of the alternative final cover system will be completed in accordance with the TCEQ Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill and findings of the Unsat-H model and report found in Appendix 3N - Closure Details. For the alternative cover, the support layer will be much less dense than the infiltration material utilized in the prescriptive cover. The Interstate Technology and Regulatory Council (ITRC) Alternative Landfill Technologies Team states that a range of 75-85% compaction is best for evapotranspiration monolithic soil final cover systems. This layer will be placed at 80% compaction.

The erosion layer will be installed in accordance to the TCEQ Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill and finding of the Unsat-H model and report found in Appendix 3N. This layer will be placed at 90% compaction.

3.8.1.6 Final Cover Construction Activities for both Prescriptive and Alternative Systems

A gas venting system will be implemented to dissipate the gas produced by anaerobic degradation of the waste at the site. Drawings P3-41 and P3-42, in Appendix 3M - Landfill Gas Management Details, provide landfill gas venting system details. Any gas collection system used at the site will be designed and installed with approval of the TCEQ.

Erosion and soil loss preventative measures and maintenance will be required for the final cover. Calculations using the Revised Universal Soil Loss Equation (RUSLE) for estimating soil loss on the final cover of the landfill can be seen in Appendix 3B, Attachment 5 – Closure Soil Loss Calculations. Refer to Appendix 3G for slope stability analysis.

3.8.2 Largest Area Requiring Final Cover

30 TAC §330.457(e)(2)

The total final cover area at the McCombs Landfill is not expected to exceed approximately 222.8 acres for areas that will ever require final cover. The landfill development plan has been broken into different sections to be constructed over time and therefore smaller sections of the total may be closed individually or collectively as

they reach permitted maximum elevations. The largest area of closure is during Sector G development, prior to the closure of Sector F, for which the total open area is 113.2 acres and the incremental closure area is 18.3 acres. Also included at that time will be 70.8 acres in the existing unlined landfill area and 20.5 acres lined landfill area in the existing Phase I and II areas. The filling sequence is provided in the Appendix 3E - Site Layout Plans.

3.8.3 Maximum Waste Inventory

30 TAC §330.457(e)(3)

Approximately 5,964,060 cubic yards (cy) of waste (and intermediate cover) have been landfilled in the existing completed phases of the Landfill, as of December 31, 2010.

The total Landfill volume was estimated using AutoCAD by comparing the top of geomembrane to the top of final cover. The total remaining Landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including waste and daily**,** intermediate, and final cover), which provides capacity through 2014 based on table 3H-1 in Appendix 3H-Site Life Projections. The total remaining Landfill volume available for waste disposal including the remainder of Sector A and all subsequent planned sectors (B through K) is 62,532,764 CY. Given the remaining capacity above, the remaining estimated life of the Landfill is until 2059. The total volume in place at that time will be 68,496,824 CY.

3.8.4 Closure Schedule

30 TAC §330.457(e)(4), 330.457(f), and 330.457(g)

The McCombs Landfill will be efficiently closed by the following procedure:

- The Owner/Operator will provide written notification to the TCEQ within 45 days prior to beginning final closure activities stating their intent to close a section of the facility or the entire facility site. This notice will also be placed in the operating record.
- The Owner/Operator will publish a public notice of final closure in the largest circulating newspaper in the facility area within 90 days prior to beginning final closure activities of the entire facility site. This notice will include name, address, location of the facility, permit number, and date of final receipt of waste. Copies of the final closure plan will be made available for the public to review.
- At least one sign will be posted at the main entrance (and others where appropriate around the site perimeter) following the closure date notifying readers of the final date of closure.
- Barriers shall be installed at all entrances, gates, or access points to the Landfill following closure in order to prevent unauthorized dumping of solid waste.
- Final closure for the entire facility site shall begin no later than 30 days after the date on which the Landfill receives final waste. If the Landfill has remaining

capacity and will likely continue to receive additional waste then final closure will continue no later than one year after receipt of final waste. If time beyond the one year is necessary, a request for extension may be submitted to the executive director for review and approval. The request must include documentation demonstrating the site had capacity to receive additional waste and that the owner/operator has taken steps and will continue to take steps to prevent threats to human health and environment from the unclosed portions of the site.

- The Final closure in accordance with this plan shall be completed within 180 of initiation of final closure activities. If it is likely to take beyond 180 days, an extension can be requested in writing to the executive director. The request must include all documentation demonstrating that closure will take longer than 180 days and that the owner/operator has taken steps and will continue to take steps to prevent threats to human health and environment from the unclosed portions of the site.
- Documented certification by an independent licensed Professional Engineer will be submitted to the TCEQ following completion of final closure certifying completion in accordance with the final closure plan and including all documentation necessary for certification of final closure. A copy of the approved certification from the TCEQ will be placed in the operating record.
- Within 10 days of final completion of closure activities for the Landfill, the owner/operator will submit a certified copy of an Affidavit to the Public to the Executive Director. A copy will also be placed in the operating record. The affidavit will include an updated metes and bounds description of the extent of the disposal areas.
- A certified notation will be recorded on the deed to the property the facility is on that will in perpetuity notify a potential purchaser that the land has previously been used as a landfill. The use of this land will be restricted to the provisions specified in Section 3.9 - Post-Closure Plan. The owner/operator will submit a certified copy of the modified deed to the Executive Director and place a copy in the site operating record within 10 days of final completion of closure activities for the Landfill.

3.8.5 Final Contour Map

30 TAC §330.457(e)(5)

A final contour map depicting the ~~proposed~~ final contours, 100-year floodplain, and establishing top slopes and sideslopes for the McCombs Landfill is provided in Appendix 3E - Site Layout Plan, Drawing P3-16. No structural designs for collection and conveyance along the top and side slopes (i.e., berms, dikes, chutes) are recommended as the ~~proposed~~ final cover design meets the requirements for soil loss and non-erodible velocities.

3.8.6 Final Closure Costs

30 TAC §330.503

The estimated cost to hire a third party to perform the closure project (for the largest area to ever require final cover, identified in section 3.3.2) can be found in Appendix 3N, Attachment 3 - Closure Cost Estimates.

Additionally, in order to comply with 30 TAC §330.503(b), a copy of the City's current financial assurance cost estimates for the facility are provided in Appendix 3N, Attachment 3 ~~(reference Permit Number MSW 729A)~~.

The Final Closure Plan has been prepared in compliance with applicable regulations (30 TAC §***330.63(h), 330.457, and 330.459***~~330.253~~) for the McCombs Landfill. Within 180 days of the last receipt of wastes for any MSWLF unit, the owner or operator will complete the installation of a final cover system as permitted, designed and constructed to minimize infiltration and erosion. This final closure plan includes the following:

- A description of the prescriptive final cover design, including methods for installation;
- A description of the alternative final cover design, including justification in accordance with the *Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill,* and methods for installation;
- An estimate of the largest area requiring final cover at any time during the active life of the landfill;
- An estimate of the maximum inventory of wastes on-site over the active life of the landfill; and
- A schedule for completing all final cover activities.

A copy of this closure plan will be included in the site operating record.

The Final Contour Map for the Landfill depicting the proposed final contours, site access roads, top and side slopes, and proposed surface drainage features is located in Appendix 3E - Site Layout Plans.

The estimated cost to hire a third party to perform the closure project can be found in Appendix 3N, Attachment 2 - Closure Cost Estimates.

3.8.1 Description of Final Cover Design

30 TAC §330.457(e)(1)

The final cover will be applied to areas of the landfill as they reach final contour elevations shown on the Final Cover Plan in Appendix 3G - Construction Design Details, Drawing P3-33~~ to meet the requirements of 30 TAC §330.253(c)(1) and (2)~~. The prescriptive final cover for areas of the Landfill with a synthetic bottom liner consists of a minimum of a***n eighteen*** ~~six~~ inch ***infiltration*** ~~sand buffer~~ layer over the intermediate and daily cover layers ***having a coefficient of permeability less than or equal to 1x10^{-5} cm/sec***. The ***infiltration*** ~~buffer~~ layer is then overlain with a synthetic flexible membrane with permeability less than that of the bottom liner system. ***Twelve*** ~~18~~ inches of earthen material~~, having a permeability coefficient less than or equal to 1 X 10^{-5} cm/sec, is placed on top of the liner,~~ ***are then placed,*** providing the erosion layer. On top of the erosion layer, six inches of vegetative layer (or 4 inches of rock

layer) is placed that can support and sustain native plan growth. The rock layer, if used instead of the vegetative layer, would consist of rounded to sub-rounded river rock, crushed angular to sub-angular rock, or a combination of the two.

The synthetic membrane shall be a minimum of 40 mils (LLDPE) to ensure proper seaming. Drawing P3-34 in Appendix 3G - Construction Design Details, shows details for the prescriptive final cover system design for areas of the landfill that have a synthetic bottom liner. Drawing P3-29 in Appendix 3G details the Typical Landfill Perimeter Section, which shows how the liner is anchored to the existing grades.

The City of El Paso is proposing an alternative final cover system option for the McCombs Landfill. The alternative cover system includes only soil cover as opposed to a synthetic liner. The system will include the 12 inches of preliminary cover (6 inches of daily cover and 6 inches of intermediate cover) as is in the prescriptive cover, 12 inches of vegetative support soil and 12 inches of vegetative topsoil. The 24" alternative final cover is in lieu of the low permeability soil, synthetic membrane liner and topsoil (or rock) described in the prescriptive cover above. Drawing P3-35 in Appendix 3G provides detail on the alternative final cover profile.

Appendix 3N - Closure Details presents a demonstration of the infiltration equivalency of the two final cover system options and justification for the alternative earth cover in accordance with the "*Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill"*.

Appendix 3B, Attachment 5 presents the calculated soil loss for the two final cover system options.

The prescriptive cover sequencing will be different for areas with bottom liner than for those without and both are described below.

3.8.1.2 Sequence of the ~~Prescriptive~~ Final Cover Installation

The following provides a general sequencing plan for the prescriptive final cover system installation for the Landfill areas that include a synthetic bottom liner:

- Apply the final six inches of daily cover, and if not closed within 180 days apply six inches of intermediate cover;
- ~~Place 6 inches of sand buffer (with a coefficient of permeability less than or equal to 1 X 10^{-3} cm/sec);~~
- ***Place 18 inches of earthen material (with a coefficient of permeability less than or equal to 1 X 10^{-5} cm/sec) that will serve as the infiltration layer;***
- Place 40 mil LLDPE geomembrane;
- Place ***12***~~1~~8 inches of earthen material ~~(with a coefficient of permeability less than or equal to 1 X 10^{-5} cm/sec)~~ that will serve as the ***erosion*** ~~infiltration~~ layer;
- Place the 6 inch minimum earthen vegetative layer that is capable of supporting and sustaining native plant growth (or place 4 inches of crushed rock or river rock armoring in lieu of 6 inch earthen vegetative layer); and

- Refer to Drawing P3-34 - Final Cover Details, in Appendix 3G for details of this final cover system design.

The following provides a general sequencing plan for the prescriptive final cover system installation for the McCombs Landfill areas that do not include a synthetic bottom liner:

- Apply the final six inches of daily cover, and if not closed within 180 days apply six inches of intermediate cover;
- Place 18 inches of earthen material (with a coefficient of permeability less than or equal to 1 X 10^{-5} cm/sec) that will serve as the infiltration layer;
- Place the 6 inch minimum earthen vegetative layer that is capable of supporting and sustaining native plant growth (or place 4 inches of crushed rock or river rock armoring in lieu of 6 inch earthen vegetative layer);
- Refer to Drawing P3-34 in Appendix 3G for details of this final cover system design.

The following provides a general sequencing plan for the alternative final cover system installation for the McCombs Landfill areas (both with and without a synthetic bottom liner:

- Apply the final six inches of daily cover and 6 inches of intermediate cover;
- Apply ***6***~~12~~ inches of v~~egetative~~ support soil ***compacted to 80%*** ~~that has sufficient capacity to store infiltrated water in the cover system until removed by evaporation or transpiration~~;
- Apply ***18***~~12~~ inches of ***erosion soil compacted to 90%*** ~~vegetative topsoil that will support the establishment of vegetative cover of native plant material~~;
- ***Apply 4 inches of top layer consisting of rock armor;***
- Refer to Drawing P3-35 - Proposed Alternative Cover Details, in Appendix 3G for details of this final cover system design.

3.8.1.3 Site Preparation

Site preparation includes clearing and grubbing vegetation in areas to receive intermediate cover. The intermediate cover will be prepared and graded to meet the criteria set forth in the Final Cover Quality Control Plan. Additional clean fill material from on-site native soil can be used to meet the required contour elevations.

3.8.1.4 Prescriptive Final Cover Construction

Testing and Evaluation of the prescriptive final cover system will be completed in accordance with 30 TAC §***330.457(c)***~~330.253(f)~~. For the prescriptive cover, the infiltration material will be placed in accordance with the Final Cover Quality Control Plan ***(located in Appendix 3P)*** and will be tested at least once per surface acre for coefficient of permeability. Permeability data will be submitted to the TCEQ

executive director. A liquid limit (LL) of not less than 30 and a plasticity index (PI) of not less than 15 are required, but lower values of Atterburg limits may be acceptable.

The remaining layers (membrane, erosion and vegetative or rock layers) will be installed in accordance with the Final Cover Quality Control Plan. If rock is chosen as the final layer, it will be graded to provide an interlocking framework for slope stability and to minimize erosion for surface water.

3.8.1.5 Alternative Final Cover Construction

Testing and Evaluation of the alternative final cover system will be completed in accordance with the TCEQ Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill and findings of the Unsat-H model and report found in Appendix 3N - Closure Details. For the alternative cover, the ~~vegetative~~ support layer will be much less dense than the infiltration material utilized in the prescriptive cover. The Interstate Technology and Regulatory Council (ITRC) Alternative Landfill Technologies Team states that a range of 75-85% compaction is best for evapotranspiration monolithic soil final cover systems. This layer will be placed at 80% compaction.

The ***erosion*** ~~vegetative topsoil~~ layer will be installed in ***accordance to the*** TCEQ Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill and finding of the Unsat-H model and report found in Appendix 3N. This layer will be placed at ***90***~~75~~% compaction.

3.8.1.6 Final Cover Construction Activities for both Prescriptive and Alternative Systems

A gas venting system will be implemented to dissipate the gas produced by anaerobic degradation of the waste at the site. Drawings P3-41 and P3-42, in Appendix 3M - Landfill Gas Management Details, provide landfill gas venting system details. Any gas collection system used at the site will be designed and installed with approval of the TCEQ.

Erosion and soil loss preventative measures and maintenance will be required for the final cover. Calculations using the Revised Universal Soil Loss Equation (RUSLE) for estimating soil loss on the final cover of the landfill can be seen in Appendix 3B, Attachment 5 – Closure Soil Loss Calculations. Refer to ***Appendix 3G*** ~~the Danny R. Anderson Consultants (DRA) Report, dated January 1984~~ for slope stability analysis.

3.8.2 Largest Area Requiring Final Cover

30 TAC §330.457(e)(2)

The total final cover area at the McCombs Landfill is not expected to exceed approximately 222.8 acres for areas that will ever require final cover. The landfill development plan has been broken into different sections to be constructed over time and therefore smaller sections of the total may be closed individually or collectively as they reach permitted maximum elevations. The largest area of closure is during Sector

G development, prior to the closure of Sector F, for which the total open area is 113.2 acres and the incremental closure area is 18.3 acres. Also included at that time will be 70.8 acres in the existing unlined landfill area and 20.5 acres lined landfill area in the existing Phase I and II areas. The filling sequence is provided in the Appendix 3E - Site Layout Plans.

3.8.3 Maximum Waste Inventory

30 TAC §330.457(e)(3)

Approximately 5,964,060 cubic yards (cy) of waste (and intermediate cover) have been landfilled in the existing completed phases of the landfill, as of December 31, 2010.

The total landfill volume was estimated using AutoCAD by comparing the top of geomembrane to the top of final cover. The total remaining landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including ~~both~~ waste and daily***, intermediate, and final*** cover), which provides capacity through 2014 based on table 3H-1 in Appendix 3H-Site Life Projections. The total remaining landfill volume available for waste disposal including the remainder of Sector A and all subsequent planned sectors (B through K) is 62,532,764 CY. Given the remaining capacity above, the remaining estimated life of the landfill is ***until 2059***~~49 years~~. The total ***volume*** ~~waste~~ in place at that time will be 68,496,824 CY.

3.8.4 Closure Schedule

30 TAC §330.457(e)(4), 330.457(f), and 330.457(g)

~~In accordance with 30 TAC §330.253, the~~ ***The*** McCombs Landfill will be efficiently closed by the following procedure:

- The Owner/Operator will provide written notification to the TCEQ within 45 days prior to beginning final closure activities stating their intent to close a section of the facility or the entire facility site. This notice will also be placed in the operating record.
- The Owner/Operator will publish a public notice of final closure in the largest circulating newspaper in the facility area within 90 days prior to beginning final closure activities of the entire facility site. This notice will include name, address, location of the facility, permit number, and date of final receipt of waste. Copies of the final closure plan will be made available for the public to review.
- At least one sign will be posted at the main entrance (and others where appropriate around the site perimeter) following the closure date notifying readers of the final date of closure.
- Barriers shall be installed at all entrances, gates, or access points to the Landfill following closure in order to prevent unauthorized dumping of solid waste.
- Final closure for the entire facility site shall begin no later than 30 days after the date on which the Landfill receives final waste. If the Landfill has remaining

capacity and will likely continue to receive additional waste then final closure will continue no later than one year after receipt of final waste. If time beyond the one year is necessary, a request for extension may be submitted to the executive director for review and approval. The request must include documentation demonstrating the site had capacity to receive additional waste and that the owner/operator has taken steps and will continue to take steps to prevent threats to human health and environment from the unclosed portions of the site.

- The Final closure in accordance with this plan shall be completed within 180 of initiation of final closure activities. If it is likely to take beyond 180 days, an extension can be requested in writing to the executive director. The request must include all documentation demonstrating that closure will take longer than 180 days and that the owner/operator has taken steps and will continue to take steps to prevent threats to human health and environment from the unclosed portions of the site.
- Documented certification by an independent licensed Professional Engineer will be submitted to the TCEQ following completion of final closure certifying completion in accordance with the final closure plan and including all documentation necessary for certification of final closure. A copy of the approved certification from the TCEQ will be placed in the operating record.
- Within 10 days of final completion of closure activities for the Landfill, the owner/operator will submit a certified copy of an Affidavit to the Public ***to*** ~~on a form provided by~~ the Executive Director ~~to the TCEQ~~. A copy will also be placed in the operating record. The affidavit will include an updated metes and bounds description of the extent of the disposal areas.
- A certified notation will be recorded on the deed to the property the facility is on that will in perpetuity notify a potential purchaser that the land has previously been used as a landfill. The use of this land will be restricted to the provisions specified in Section 3.9 - Post-Closure Plan. ***The owner/operator will submit a certified copy of the modified deed to the Executive Director and place a copy in the site operating record within 10 days of final completion of closure activities for the Landfill.***

3.8.5 Final Contour Map

30 TAC §330.457(e)(5)

A final contour map ***depicting the proposed final contours, 100-year floodplain, and establishing top slopes and sideslopes*** for the McCombs Landfill is provided ***in*** Appendix 3E - Site Layout Plan, Drawing P3-16. ***No structural designs for collection and conveyance along the top and side slopes (i.e., berms, dikes, chutes) are recommended as the proposed final cover design meets the requirements for soil loss and non-erodible velocities.***

3.8.6 Final Closure Costs

30 TAC §330.503

The estimated cost to hire a third party to perform the closure project (for the largest area to ever require final cover, identified in section 3.3.2) can be found in Appendix 3N, Attachment ***3***~~2~~ - Closure Cost Estimates.

Additionally, in order to comply with 30 TAC §330.503(b), a copy of the City's current financial assurance cost estimates for the facility are provided in Appendix 3N, Attachment 3 (reference Permit Number MSW 729A).

The Post-Closure Plan has been prepared in compliance with applicable regulations (30 TAC §330.463(b) and 330.465) for the McCombs Landfill. Post-closure care maintenance will begin upon completion of final-closure activities and approval by the TCEQ. This post closure plan includes the following:

- Provisions for groundwater and landfill gas monitoring, leachate collection, and maintenance activities for the final cover system and drainage facilities to be conducted during post-closure care period, and the frequency at which these activities will be performed;
- Provisions for reducing the post-closure care period;
- ~~A Vegetation Establishment Verification Plan for the Evapotranspiration (ET) Alternate Final Cover closure option;~~
- The Name, address, and phone number for the responsible party in charge of the post-closure care activities during the duration of the 30-year post-closure period; and
- Provisions for certification at the completion of the post-closure care period.

3.9.1 Post-Closure Monitoring and Maintenance Activities

The period of post-closure will be 30 years unless approval from TCEQ allows a change in duration. The City of El Paso will maintain the right of entry and all right-of-ways to the facility throughout this period. Maintenance activities include annual site inspections (unless otherwise stated below) with a written summary and will consist of, but are not limited to the following:

- Maintenance and/or remediation activities, as needed, to maintain the integrity and effectiveness of the final cover system, site vegetation, and storm water drainage control systems. Activities may include regrading, addition of soil, seeding, and erosion and sedimentation control structure repairs;
- Control surface run-on and run-off in order to minimize erosion of the final cover system. Activities may include regarding, addition of soil, seeding, and erosion and sedimentation control structure repairs or cleaning;
- Control of undesirable vegetation growth on the final cover system;
- Correct the effects of settlement, subsidence, ponded water, erosion, or other events or failures in as much as these situations are detrimental to the integrity of the closed landfill. Activities may include regarding, addition of soil, seeding, or removal of water or sediment;
- Maintain the integrity of on-site structures, roads, gates and fences;

- Maintain groundwater monitoring in accordance with Section 3.6, Groundwater Sampling and Analysis Plan and 30 TAC §330.401-330.421. The monitoring frequency shall be semi-annual. Parameters to be monitored will be in accordance with 30 TAC §330.419 unless otherwise approved by the TCEQ;
- Maintain and operate the leachate control system in accordance with Section 3.5, Waste Management Unit Design Plan, Appendix 3I, Leachate and Contaminated Water Plan, and 30 TAC §330.331 and 330.333 unless otherwise approved by the TCEQ and leachate no longer poses a threat to human health and the environment;
- Maintain and operate the landfill gas monitoring system in accordance with Section 3.7, Landfill Gas Management Plan and 30 TAC §330.371. Monitoring frequency shall be quarterly unless otherwise approved by the TCEQ;
- Retain the Site Operating Record and documentation of post-closure care activities, including monitoring results and records of inspections and maintenance performed;
- Maintain the required benchmark and landfill markers; and
- Repair/Replace gas probes, gas extraction wells, leachate collection and removal system components, groundwater monitoring system components as necessary.

3.9.2 Post-Closure Care Period

The length of the post-closure maintenance period may be decreased or increased by the TCEQ. If the Landfill submits documentation, signed by an independent registered professional engineer, that demonstrates that a reduced period will sufficiently protect human health and the environment, the TCEQ may review and approve a decrease in the post-closure care period. If it is determined that an increased duration is necessary to protect human health and the environment, notification will be given to the Landfill prior to any such change by the TCEQ.

Certification of completion of the post-closure care period and voluntary permit revocation will be in accordance with 30 TAC §330.465 upon completion of the post-closure care maintenance period. The Landfill must submit a documented certification, signed by an independent registered professional engineer, verifying the post-closure care has been in accordance with the approved plan. The submittal shall also include all necessary documentation for certification of completion of post-closure care.

~~3.9.3 Vegetation Establishment Verification Plan~~

~~The following plan will be used to verify that the established vegetation on the ET Alternate final cover option is consistent with the Alternative Final Cover Plan and the TCEQ Guidance for Authorizing a Water Balance Alternative Final Cover for a Municipal Solid Waste Landfill (TCEQ Guidance). As discussed in Appendix 3N – Closure Details, the establishment of vegetation is a crucial component of the ET cap system. In addition, the post-closure care period for the facility, if utilizing the ET cover, will not begin until the cover has been completely constructed and the vegetation has been established.~~

This plan includes the following:

- Vegetation Establishment and Maintenance
- Vegetation Performance Specification
- Vegetation Establishment Report

3.9.3.1 Vegetation Establishment and Maintenance

The vegetation establishment period will begin after the Final Cover System Evaluation Report and Certification has been submitted and approved by the TCEQ. This period ends when the Vegetation Establishment Report has been submitted and approved by the TCEQ. This time period is typically two to three years in length at the beginning of the Post-Closure Care Period.

Maintenance activities during this period should be performed to ensure that the vegetation established during construction continues to meet the vegetation performance specification. These activities may include "reseeding, fertilizing, irrigating, and restoring cover that has been eroded or damaged (for example, by burrowing of animals)" as described in the TCEQ Guidance. Care should also be taken to avoid driving vehicles with greater than 16 psi ground pressure on the ET cover area during establishment of vegetation. If such a vehicle is necessary, the area shall be evaluated and repaired as appropriate.

3.9.3.2 Vegetation Performance Specification

The vegetation performance specification is included in the Alternative Cover Plan in Appendix 3N. In summary, the alternative cover plan included 10 percent vegetative cover with a nominal grass height of five inches. The plan also specifies a root depth of 30 inches as the modeled maximum root penetration in the UNSAT-H model. If this root depth is not reached, a site specific depth may be modeled to show equivalency.

3.9.3.3 Vegetation Establishment Report

The Vegetation Establishment Report, as required by the TCEQ, will be submitted quarterly during cover vegetation start-up, indicating:

- The type and quantity of vegetation that has been established,
- The percent of vegetative cover established, and
- The vegetative root structure (depth and density).

If the criteria above do not meet the specification, corrective action must be taken to ensure that the vegetation is consistent with the ET cover design. At the end of the establishment period, this report, signed by a licensed Texas Professional Engineer, must be approved by the TCEQ. Once approved, the vegetation establishment period is completed.

3.9.3 Contact for Post-Closure Activities

The following is the current responsible party overseeing the post-closure care maintenance activities for the facility:

The City of El Paso
Environmental Services
7968 San Paulo Drive
El Paso, Texas 79907
Phone: (915) 621-6700
Fax: (915) 621-6711

The person responsible for post-closure care activities is subject to change. In the event there is a change, the TCEQ will be notified.

3.9.4 Post-Closure Land Use

Other than open space, there are no proposed uses or plans at this time for the McCombs Landfill following closure. Any proposed uses will be submitted to the TCEQ for review and approval.

3.9.5 Post-Closure Costs

30 TAC §330.507

The estimated costs associated with post-closure care maintenance of the McCombs Landfill can be found in Appendix 3O - Post-Closure Details.

Additionally, in order to comply with 30 TAC §330.503(b), a copy of the City's current financial assurance cost estimates for the facility are provided in Appendix 3N, Attachment 3 (reference Permit Number MSW 729A).

SAIC®

The Erosion and Sedimentation Control Plan has been developed to provide proper management and control measures for existing and developed conditions. These measures will provide management of soil erosion and control of sedimentation due to stormwater runoff.

3B.1 Drainage Conditions

The McCombs Landfill is an existing municipal solid waste disposal facility located in Section 6, Block 80, Township 1, within the city limits of El Paso, at the intersection of McCombs Road and FM 2529 (Stan Roberts Sr. Road). The site covers 347 acres and the surrounding areas are largely undeveloped. To the west of McCombs Road is the Public Service Board - El Paso Water Utilities' Sludge Monofill.

The soils in the Landfill area are predominantly Turney-Berino Association, moderately deep over soft caliche, in the Hueco Bolson. The soils are characterized as moderately permeable, having high water-holding capacity, and having a slow runoff rate. Caliche covers the entire Bolson surface and ranges in thicknesses of immeasurable to 8 feet thick.

3B.1.1 Existing Conditions

The existing drainage patterns and flow rates are shown on Drawing P3-4 - Existing Drainage Conditions in Appendix 3C.

Stormwater runoff is collected in a v-ditch around the perimeter of the Landfill units and is directed into an existing stormwater pond. Runoff from north of the existing Landfill is currently captured within the mined pit area. Some of the runoff in the northwest corner continues to the site of existing Retention Pond A. Runoff generated to the east is captured in the mined pit area. Runoff generated in the existing landfill areas is conveyed into existing Retention Pond D, west of the existing fee house, and existing Retention Pond E, in the southeastern corner of the developed Landfill area. These exiting stormwater patterns are shown on Drawing P3-4 - Existing Drainage Conditions, in Appendix 3C. Stormwater from the 19.4 acre site entrance facilities area (existing conditions) generally flows to natural low lying areas and infiltrates.

There is an area of the Landfill, including Pond A, to the northwest corner that lies within the 100-year floodplain as shown on the Flood Insurance Rate Map (FIRM) Panel No. 480214 0004 C and Appendix 3D, Drawing P3-14 – 100-Year Floodplain Map. The base flood elevations (BFE's) were converted from NGVD 29 Datum to the City of El Paso Vertical Datum with a factor provided by Land-Mark Professional Surveying Incorporated. As shown on Drawing P3-8, the BFE's are below the site berms located around the site, and therefore the 100-year flood will be diverted around the Landfill site to the north and will not affect stormwater elevations within Pond A

nor will the BFE's affect Landfill operations. The FIRM map is provided in Appendix 3D, Drawing P3-13.

3B.1.2 Developed Conditions

The Landfill Completion Plan is provided as Drawing P3-16 in Appendix 3E–and shows all final developed conditions. The final contours include four ponds to break up drainage areas (the existing Retention Ponds A and E, and Ponds B and C), and in effect reduce sheet flow and minimize erosion. Existing Pond D is no longer needed as that area is filled to grade and flow is conveyed in a v-ditch to Pond E.

During construction, temporary diversions and drainage swales will be constructed to prevent unauthorized discharge of surface water and sediment. The final developed conditions will include perimeter v-ditches and ponding areas to control all site stormwater runoff. The retention ponds on site do not have an outlet structure and water will drain down via infiltration or evaporate. Drawing P3-6 in Appendix 3C shows final drainage conditions and controls.

The final drainage conditions plan for the site entrance facilities area is provided as Drawing C-13 in Appendix 3E. Stormwater from the site entrance facilities area will be contained in one of six onsite detention areas (labeled as DA-1 through DA-6). All runoff from the site will be contained in onsite retention basins.

3B.2 Erosion and Sedimentation Controls

3B.2.1 TPDES Multi-Sector General Permit

The facility has been designed to prevent discharge of pollutants into waters of the State or waters of the United States, as defined by the Texas Water Code and the Federal Clean Water Act. An erosion and sedimentation control plan is provided in Appendix 3C, Drawing P3-11. The McCombs Landfill submitted a notice of intent (NOI) to comply with the TPDES Multi-Sector General Permit relating to stormwater discharge and received Permit No. TXR05L795 from the TCEQ on October 28, 2011. A copy of this permit is included in Appendix 2D – TPDES Multi-Sector General Permit.

3B.2.2 Best Management Practices (BMP's) Structural Controls

During construction phases, temporary controls will be implemented for erosion and sedimentation management. Throughout the entire phasing of construction intermediate controls will be implemented and upon final closure permanent erosion control practices will be implemented.

Structural controls may include, but are not limited to, silt fence, earthen diversion berms and dikes, drainage swales, and rip-rap. These structural controls will be implemented as follows:

- Upon final completion of Landfill development and closure, perimeter v-ditches will be constructed to divert stormwater runoff to the ponding areas shown on Drawing P3-11 - Erosion Control Plan. Ditches having velocities that exceed 4 feet per second (fps) will be protected against erosion as required by the maximum

non-erodible velocities as published in the USDA-SCS Engineering Field Manual. The default lining condition for all channels with peak velocity below 4 fps is vegetative lining. For all channels with maximum velocities below 4 fps another structural control option is velocity control. These controls include either ditch checks or sediment logs, and will be placed with appropriate size and spacing to keep the velocity in the channel lower than the maximum non-erodible velocity for the selected cover conditions (1.5 fps for bare soil and 4 fps for vegetation).

- For channels where neither an appropriate lining system or velocity control system, a sediment capture and replenishment system may be used instead. Because each retention pond on the site has been designed to hold a 100-year storm plus a sediment load, these ponds will be used as temporary sediment capture facilities. After each storm event each pond which has an upstream channel which lacks appropriate lining or velocity control shall have captured sediment removed such that the pond remains at the permitted capacity. The removed sediment will be placed in the upstream channels such that they maintain their permitted shape and slope. Suggested capture structures include silt fences, and sediment traps.
- When areas of the Landfill reach final design elevations, proper care will be taken to ensure that the vegetative layer is maintained to support native plant growth or that the rock cover is properly maintained. Intermediate slopes may also be vegetated depending on the length of time the area is exposed prior to commencing final grade preparations. The site will stockpile excess soil that will be used for operations at the Landfill, and thus will vegetate a portion of the stockpile material to prevent soil erosion due to wind and water along with silt fencing measures.
- In accordance with the Final Closure Plan, Section 3.8, a vegetative layer will be established upon final closure to prevent erosion. The soils used for the vegetative layer shall be evaluated for proper nutrient contact for supporting native plant life. Areas requiring intermediate vegetative cover for erosion protection during cool seasons will be mulched and seeded with a fast germination species such as red and/or winter wheat, western wheatgrass, and tall fescue or other species as recommended by local NRCS Texas Agricultural Extension Service Officials.
- Silt fence or earthen berms will be installed around stockpile areas, construction areas, or other areas of open soil to prevent sedimentation to stormwater runoff. Other BMP's as stated above may be utilized during different phases of Landfill development.
- Silt fence, sediment traps, sediment logs, and any other sediment capture devices will be placed at the toe of slope for intermediate cover side slopes which do not receive vegetative cover as a part of a sediment capture and slope replenishment program. For this program all sediment captured by the installed structural controls will be removed from the control and replaced on the slope upstream of the control. Controls will also be placed on the side slopes which will be placed such to keep the flow velocity below 1 fps. The structural controls will be checked for sediment build-up as specified in Table 3B-2.

Parameters for the installation of the structural controls can be found in Table 3B-1.

Table 3B-1
Structural Control Parameters[A]

Control	Typical Placement	Max Spacing/ Max Drainage Area	Slope Restrictions
Silt Fence	Downstream of disturbed area which has not received permanent erosion controls	100 ft 75 ft 50 ft 25 ft	3%-5% 5%-10% 10%-20% 20%-50%
Hay Bales	Downstream of disturbed area which has not received permanent erosional controls	100 ft max spacing	3:1 max
Rock Filter Dam (Type 1)	Toe of slope, around inlets, in small ditches, and swale outlets	5 acres max	2:1 max
Rock Filter Dam (Type 2)	In larger ditches and at swale outlets	5 acres max	2:1 max
Rock Filter Dam (Type 3)	In stream flow, attached to the stream bed	5 acres max	2:1 max
Rock Filter Dam (Type 4)	In ditches and smaller channels	5 acres max	2:1 max
Ditch Checks	In swales or channels	5 acre max, spaced for desired velocity	3:1 max
Sediment Logs	In swales, channels, or on slopes	25 to 50 ft. while slowing flow, 100 ft. once at desired velocity	2:1 max

[A] – Table obtained from the Erosion and Sedimentation Control Plan by Parkhill, Smith & Cooper dated July 2009.

3B.2.3 Best Management Practices (BMP's) Non-Structural Controls

Non-structural controls include maintenance during daily operations at the Landfill. Any visual evidence of soil erosion shall be addressed by placing addition soil or adding/relocating structural controls. All drainage ways will be inspected for accumulation of sediment and maintained as necessary to ensure proper capacity for stormwater conveyance. The suggested inspection and maintenance schedule and the Controls Installation Schedule are provided in Tables 3B-2 and 3B-3, respectively. It is the Site Supervisors responsibility to ensure that these maintenance activities are completed and controls are in place and operational.

Non-Structural controls include:

- Plans and designs to disturb only the smallest area necessary to perform current activities and to minimize disruption of the natural drainage, topography, and vegetative cover features.
- Phased development to minimize the area of bare soil exposed at any given time.
- Specific plans for the stabilization of exposed surfaces in a timely manner.
- Scheduling of construction activities during the time of year with the least erosion potential.

Table 3B-2 lists suggested maintenance and inspection schedule for the Landfill.

SAIC®

The Erosion and Sedimentation Control Plan has been developed to provide proper management and control measures for existing and developed conditions. These measures will provide management of soil erosion and control of sedimentation due to stormwater runoff.

3B.1 Drainage Conditions

The McCombs Landfill is an existing municipal solid waste disposal facility located in Section 6, Block 80, Township 1, within the city limits of El Paso, at the intersection of McCombs Road and FM 2529 (Stan Roberts Sr. Road). The site covers 347 acres and the surrounding areas are largely undeveloped. To the west of McCombs Road is the Public Service Board - El Paso Water Utilities' Sludge Monofill.

The soils in the Landfill area are predominantly Turney-Berino Association, moderately deep over soft caliche, in the Hueco Bolson. The soils are characterized as moderately permeable, having high water-holding capacity, and having a slow runoff rate. Caliche covers the entire Bolson surface and ranges in thicknesses of immeasurable to 8 feet thick.

3B.1.1 Existing Conditions

The existing drainage patterns and flow rates are shown on Drawing P3-4 - Existing Drainage Conditions in Appendix 3C.

Stormwater runoff is collected in a v-ditch around the perimeter of the Landfill units and is directed into an existing stormwater pond. Runoff from north of the existing Landfill is currently captured within the mined pit area. Some of the runoff in the northwest corner continues to the site of existing Retention Pond A. Runoff generated to the east is captured in the mined pit area. Runoff generated in the existing landfill areas is conveyed into existing Retention Pond D, west of the existing fee house, and existing Retention Pond E, in the southeastern corner of the developed Landfill area. These exiting stormwater patterns are shown on Drawing P3-4 - Existing Drainage Conditions, in Appendix 3C. Stormwater from the 19.4 acre site entrance facilities area (existing conditions) generally flows to natural low lying areas and infiltrates.

There is an area of the Landfill, including Pond A, to the northwest corner that lies within the 100-year floodplain as shown on the Flood Insurance Rate Map (FIRM) Panel No. 480214 0004 C and Appendix 3D, Drawing P3-14 – 100-Year Floodplain Map. The base flood elevations (BFE's) were converted from NGVD 29 Datum to the City of El Paso Vertical Datum with a factor provided by Land-Mark Professional Surveying Incorporated. As shown on Drawing P3-8, the BFE's are below the site berms located around the site, and therefore the 100-year flood will be diverted around the Landfill site to the north and will not affect stormwater elevations within Pond A

nor will the BFE's affect Landfill operations. The FIRM map is provided in Appendix 3D, Drawing P3-13.

3B.1.2 Developed Conditions

The Landfill Completion Plan is provided as Drawing P3-16 in Appendix 3E–and shows all final developed conditions. The final contours include four ponds to break up drainage areas (the existing Retention Ponds A and E, and Ponds B and C), and in effect reduce sheet flow and minimize erosion. Existing Pond D is no longer needed as that area is filled to grade and flow is conveyed in a v-ditch to Pond E.

During construction, temporary diversions and drainage swales will be constructed to prevent unauthorized discharge of surface water and sediment. The final developed conditions will include perimeter v-ditches and ponding areas to control all site stormwater runoff. The retention ponds on site do not have an outlet structure and water will drain down via infiltration or evaporate. Drawing P3-6 in Appendix 3C shows final drainage conditions and controls.

The final drainage conditions plan for the site entrance facilities area is provided as Drawing C-13 in Appendix 3E. Stormwater from the site entrance facilities area will be contained in one of six onsite detention areas (labeled as DA-1 through DA-6). All runoff from the site will be contained in onsite retention basins.

3B.2 Erosion and Sedimentation Controls

3B.2.1 TPDES Multi-Sector General Permit

The facility has been designed to prevent discharge of pollutants into waters of the State or waters of the United States, as defined by the Texas Water Code and the Federal Clean Water Act. An erosion and sedimentation control plan is provided in Appendix 3C, Drawing P3-11. The McCombs Landfill submitted a notice of intent (NOI) to comply with the TPDES Multi-Sector General Permit relating to stormwater discharge and received Permit No. TXR05L795 from the TCEQ on October 28, 2011. A copy of this permit is included in Appendix 2D – TPDES Multi-Sector General Permit.

3B.2.2 Best Management Practices (BMP's) *Structural Controls*

During construction phases, temporary controls will be implemented for erosion and sedimentation management. Throughout the entire phasing of construction intermediate controls will be implemented and upon final closure permanent erosion control practices will be implemented.

Structural controls may include, but are not limited to, silt fence, earthen diversion berms and dikes, drainage swales, and rip-rap. These structural controls will be implemented as follows:

- Upon final completion of Landfill development and closure, perimeter v-ditches will be constructed to divert stormwater runoff to the ponding areas shown on Drawing P3-11 - Erosion Control Plan. Ditches having velocities that exceed 4 feet per second (fps) will be protected against erosion as required by the maximum

non-erodible velocities as published in the USDA-SCS Engineering Field Manual. ***The default lining condition for all channels with peak velocity below 4 fps is vegetative lining. For all channels with maximum velocities below 4 fps another structural control option is velocity control. These controls include either ditch checks or sediment logs, and will be placed with appropriate size and spacing to keep the velocity in the channel lower than the maximum non-erodible velocity for the selected cover conditions (1.5 fps for bare soil and 4 fps for vegetation).***

- ***For channels where neither an appropriate lining system or velocity control system, a sediment capture and replenishment system may be used instead. Because each retention pond on the site has been designed to hold a 100-year storm plus a sediment load, these ponds will be used as temporary sediment capture facilities. After each storm event each pond which has an upstream channel which lacks appropriate lining or velocity control shall have captured sediment removed such that the pond remains at the permitted capacity. The removed sediment will be placed in the upstream channels such that they maintain their permitted shape and slope. Suggested capture structures include silt fences, and sediment traps.***
- When areas of the Landfill reach final design elevations, proper care will be taken to ensure that the vegetative layer is maintained to support native plant growth or that the rock cover is properly maintained. Intermediate slopes may also be vegetated depending on the length of time the area is exposed prior to commencing final grade preparations. ***The site will stockpile excess soil that will be used for operations at the Landfill, and thus will vegetate a portion of the stockpile material to prevent soil erosion due to wind and water along with silt fencing measures.***
- In accordance with the Final Closure Plan, Section 3.8, a vegetative layer will be established upon final closure to prevent erosion. The soils used for the vegetative layer shall be evaluated for proper nutrient contact for supporting native plant life. ***Areas requiring intermediate vegetative cover for erosion protection during cool seasons will be mulched and seeded with a fast germination species such as red and/or winter wheat, western wheatgrass, and tall fescue or other species as recommended by local NRCS Texas Agricultural Extension Service Officials.***
- Silt fence or earthen berms will be installed around stockpile areas, construction areas, or other areas of open soil to prevent sedimentation to stormwater runoff. Other BMP's as stated above may be utilized during different phases of Landfill development.
- ~~Structural control parameters for the installation of structural controls as established in the permit revision 2 dated July 2009 by Parkhill, Smith & Cooper, Inc. in the Erosion and Sedimentation Control Plan, Table 6-E-1, are still applicable to this permit revision. The erosion and sediment control plan is provided in Appendix 3B, Attachment 6.~~
- ***Silt fence, sediment traps, sediment logs, and any other sediment capture devices will be placed at the toe of slope for intermediate cover side slopes which do not receive vegetative cover as a part of a sediment capture and slope replenishment program. For this program all sediment captured by the installed structural***

controls will be removed from the control and replaced on the slope upstream of the control. Controls will also be placed on the side slopes which will be placed such to keep the flow velocity below 1 fps. The structural controls will be checked for sediment build-up as specified in Table 3B-2.

Parameters for the installation of the structural controls can be found in Table 3B-1.

Ditch Checks	*In swales or channels*	*5 acre max, spaced for desired velocity*	*3:1 max*
Sediment Logs	*In swales, channels, or on slopes*	*25 to 50 ft. while slowing flow, 100 ft. once at desired velocity*	*2:1 max*

[A] – Table obtained from the Erosion and Sedimentation Control Plan by Parkhill, Smith & Cooper dated July 2009.

3B.2.3 Best Management Practices (BMP's) Non-Structural Controls

Non-structural controls include maintenance during daily operations at the Landfill. Any visual evidence of soil erosion shall be addressed by placing addition soil or adding/relocating structural controls. All drainage ways will be inspected for accumulation of sediment and maintained as necessary to ensure proper capacity for stormwater conveyance. The suggested inspection and maintenance schedule and the Controls Installation Schedule ***are*** provided in ~~the permit revision 2 dated July 2009 by Parkhill, Smith & Cooper, Inc. in the Erosion and Sedimentation Control Plan,~~ Tables ~~6-E-2 and 6-E-3 respectively (Appendix 3B, Attachment 6)~~***3B-2 and 3B-3, respectively***~~, are still applicable to this permit revision~~. It is the Site Supervisors responsibility to ensure that these maintenance activities are completed and controls are in place and operational.

Non-Structural controls include:

- ***Plans and designs to disturb only the smallest area necessary to perform current activities and to minimize disruption of the natural drainage, topography, and vegetative cover features.***
- ***Phased development to minimize the area of bare soil exposed at any given time.***
- ***Specific plans for the stabilization of exposed surfaces in a timely manner.***
- ***Scheduling of construction activities during the time of year with the least erosion potential.***

Table 3B-2 lists suggested maintenance and inspection schedule for the Landfill.

Table 3B-2
Structural Control Inspection Parameters[A]

Inspection Site	*Frequency*	*Corrective Action*
Intermediate Cover	*Biweekly or after storm event*	*Place additional soil in areas of erosional loss, reseed any areas with insufficient vegetative cover, use temporary controls to protect areas of severe erosional damage.*
Silt Fence and Sediment Log	*Weekly or after storm event*	*Repair any damage and remove collected sediment.*
Hay Bales	*Weekly or after storm event*	*Repair any damage, replace worn bales, and remove excess sediment.*
Final Cover – Rock Armoring	*Monthly or after storm event*	*Repair any damage with more rock, consider placement of permanent controls to protect areas of reoccurring damage.*
Final Cover – Vegetative Cover	*Monthly or after storm event*	*Reseed and fertilize any areas of insufficient cover, consider placement of permanent controls to areas of reoccurring erosional damage.*
Drainage Channels and Detention Ponds	*Monthly or after storm event*	*Remove any areas of sediment buildup, reseed areas of insufficient vegetative cover, and repair damage to structural lining.*
Culverts	*Monthly or after storm event*	*Remove any areas of sediment buildup.*
Outflow Points	*During storm event*	*Note sediment load off-site, and adjust on-site controls appropriately.*
Ditch Check	*Monthly or after storm event*	*Remove accumulated sediment, remove collected debris, repair any damage.*
Sediment Collection System	*On schedule with type of structure*	*Remove collected sediment and place on upstream section of cover. Ensure sediment collection capability is not compromised.*
Sediment Trap	*Monthly or after each storm event*	*Remove collected sediment where collected to 50% of capacity. Repair trap if needed.*

[A] – Table obtained from the Erosion and Sedimentation Control Plan by Parkhill, Smith & Cooper dated July 2009.

As per 30 TAC §330.305(e) the Landfill will be maintained such that:

1) *"The owner or operator shall maintain the collection, drainage, and/or storage units as designed, and shall restore and repair the drainage system in the event of washout or failure; and*

2) *The Owner or operator shall control erosion and sedimentation, including having interim controls for phased development."*

As the development of the Landfill progresses, the effectiveness of the erosion controls is highly dependent upon the controls being installed at the appropriate

time in the development. Timely installation of needed erosional controls will protect against significant erosion damage. Table 3B-3 contains the installation time requirements for both required and optional controls.

Table 3B-3
Controls Installation Schedule[A]

Control	*Installation Timeframe*
Silt Fence	*In concurrence with upstream disturbance*
Vegetative Cover (intermediate)	*Within 180 days of placement of section of intermediate cover*
Rock Armoring	*Within 180 days of placement of final contours*
Diversion Berms	*Within 180 days of placement of final contours*
Channel Protection (Gabion, rip-rap, ditch check, or equivalent)	*In concurrence with development of final contours*
Filter Dam	*In concurrence with upstream disturbance*
Sediment Capture System	*Within 180 days of placement of intermediate cover upstream*

[A] – Table obtained from the Erosion and Sedimentation Control Plan by Parkhill, Smith & Cooper dated July 2009.

3B.3 Wind Erosion Control

Historically the average wind speed in the City of El Paso is 8.8 miles per hour. Site soils are classified as having high potential for erosion. Wind erosion will need to be monitored and controlled during all phases of Landfill development through non-structural controls. The non-structural controls will include limiting the disturbed area to the smallest possible for the current activities, prompt stabilization of the disturbed area, and inspection and repair of disturbed area after a windy day or specific event. Wetting the access road and disturbed ground with a water truck will also help to limit wind erosion.

3B.4 Soil Loss Calculation

Calculations for soil loss have been performed using the Revised Universal Soil Loss Equation (RUSLE) as provided by the National Resource Conservation Service (NRCS), El Paso office. This calculation demonstrates long-term erosion stability of the Landfill and an estimation of soil loss as required by the TCEQ Solid Waste Regulations. Calculations can be seen in Appendix 3B, Attachment 5 – Closure Soil Loss Calculations. The utilized soil loss RUSLE values are provided in Appendix 3B, Attachment 5~~ as well as in the Erosion and Sedimentation Control Plan completed by Parkhill, Smith & Cooper, Inc. (revision 2 dated July 2009) included in Appendix 3B, Attachment 6~~. It should be noted that the rainfall value "R" has been updated from previous calculations provided to the TCEQ, as it appears the value previously used was incorrect for the City of El Paso.

The soil loss calculations for final cover conditions and intermediate cover conditions are summarized below in Table 3B-~~1~~***4***.

Table 3B-~~1~~*4*
Soil Loss Calculation Results

Cover Conditions	Location	Cover Type	Soil Loss (tons/acre-year)
Interim Cover	Side Slope	N/A[C]	7.43[B]
Intermediate Cover	Side Slope	N/A[C]	6.48[B]
Final Cover	Side Slope	Vegetation	1.12[A]
Final Cover	Side Slope	Rock Cover	0.27[A]
Intermediate Cover	Top Dome	N/A[C]	1.10[B]
Final Cover	Top Dome	Vegetation	0.19[A]
Final Cover	Top Dome	Rock Cover	0.05[A]

[A] – TCEQ maximum recommended loss for final cover conditions is 2 tons/acre-year.

[B] – TCEQ maximum recommended loss for intermediate cover conditions is 50 tons/acre-year.

[C] – It is assumed that the interim and intermediate cover will have no ground cover.

3B.5 Non-Erodible Velocities

In accordance with 30 TAC §330.305(d)(1), estimated peak velocities for top surfaces and external embankment slopes have been compared to the permissible non-erodible velocities under similar conditions. ~~The permissible non-erodible velocities were obtained from the Erosion and Sedimentation Control Plan by Parkhill, Smith & Cooper, Inc. (revision 2 dated July 2009) included in Appendix 3B, Attachment 6.~~ Top surfaces and external embankment slopes were designed to minimize erosion and soil loss through the use of appropriate side slopes, vegetation, and other structural and non-structural controls during all phases of Landfill operation in accordance with 30 TAC §330.305(d)(2). Table 3B-~~2~~***5*** provides the maximum velocity for each service compared to the permissible velocity for the cover condition. Calculations for each drainage area are provided in Appendix 3B, Attachment ~~7~~***6*** – Drainage Calculations.

Table 3B-~~25~~
Non-Erodible Velocities

Flow Surface	Condition	Max Velocity (fps)	Max Non-Erodible Velocity (fps)[A]	Acceptable
		Intermediate Cover		
Interim Side Slope (3:1)	Non-Vegetated	1.19	1.5	Yes
External Side Slope (3:1)	Non-Vegetated	1.24	1.5	Yes
Top Dome (7%)	Non-Vegetated	0.69	1.5	Yes
		Final Cover		
External Side Slope (3:1)	Vegetated	1.55	4.0	Yes
Top Dome (7%)	Vegetated	1.15	4.0	Yes
External Side Slope (3:1)	Rock Armored	3.09	20	Yes
Top Dome (7%)	Rock Armored	2.30	20	Yes
		Channels		
Channel 1	Rip Rap	4.40	20.0	Yes
Channel 2	Concrete	6.74	20.0	Yes
Channel 3	Rip Rap	4.69	20.0	Yes
Channel 4	Vegetated	3.42	4.0	Yes
Channel 5	Rip Rap	4.07	20.0	Yes

A – Value obtained from the Erosion and Sediment Control Plan by Parkhill, Smith & Cooper dated July 2009.

~~UPDATE GROUNDWATER/ SURFACE WATER PROTECTION PLAN~~

CITY OF EL PASO

SHEET TITLE
EROSION CONTROL DETAILS

DRAWING:
~~A116-F2a~~
App 3B, F1

The Erosion and Sedimentation Control Plan has been developed to provide proper management and control measures for existing and developed conditions. These measures will provide management of soil erosion and control of sedimentation due to stormwater runoff.

3B.1 Drainage Conditions

The McCombs Landfill is an existing municipal solid waste disposal facility located in Section 6, Block 80, Township 1, within the city limits of El Paso, at the intersection of McCombs Road and FM 2529 (Stan Roberts Sr. Road). The site covers ***347*** ~~327~~ acres and the surrounding areas are largely undeveloped. To the west of McCombs Road is the Public Service Board - El Paso Water Utilities' Sludge Monofill.

The soils in the Landfill area are predominantly Turney-Berino Association, moderately deep over soft caliche, in the Hueco Bolson. The soils are characterized as moderately permeable, having high water-holding capacity, and having a slow runoff rate. Caliche covers the entire Bolson surface and ranges in thicknesses of immeasurable to 8 feet thick.

3B.1.1 Existing Conditions

The existing drainage patterns and flow rates are shown on Drawing P3-4 - Existing Drainage Conditions in Appendix 3C.

Stormwater runoff is collected in a v-ditch around the perimeter of the Landfill units and is directed into an existing stormwater pond. Runoff from north of the existing Landfill is currently captured within the mined pit area. Some of the runoff in the northwest corner continues to the site of existing Retention Pond A. Runoff generated to the east is captured in the mined pit area. Runoff generated in the existing landfill areas is conveyed into existing Retention Pond D, west of the existing fee house, and existing Retention Pond E, in the southeastern corner of the developed Landfill area. These exiting stormwater patterns are shown on Drawing P3-4 - Existing Drainage Conditions, in Appendix 3C. ***Stormwater from the 19.4 acre site entrance facilities area (existing conditions) generally flows to natural low lying areas and infiltrates.***

There is an area of the Landfill, including Pond A, to the northwest corner that lies within the 100-year floodplain as shown on the Flood Insurance Rate Map (FIRM) Panel No. 480214 0004 C and Appendix 3D, Drawing P3-14 – 100-Year Floodplain Map. The base flood elevations (BFE's) were converted from NGVD 29 Datum to the City of El Paso Vertical Datum with a factor provided by Land-Mark Professional Surveying Incorporated. As shown on Drawing P3-8, the BFE's are below the site berms located around the site, and therefore the 100-year flood will be diverted around the Landfill site to the north and will not affect stormwater elevations within Pond A

nor will the BFE's affect Landfill operations. The FIRM map is provided in Appendix 3D, Drawing P3-13.

3B.1.2 Developed Conditions

The Landfill Completion Plan is ***provided as Drawing P3-16*** ~~shown~~ in Appendix 3E~~, Drawing P3-16~~ and shows all final developed conditions. The final contours include four ponds to break up drainage areas (the existing Retention Ponds A and E, and Ponds B and C), and in effect reduce sheet flow and minimize erosion. Existing Pond D is no longer needed as that area is filled to grade and flow is conveyed in a v-ditch to Pond E.

During construction, temporary diversions and drainage swales will be constructed to prevent unauthorized discharge of surface water and sediment. The final developed conditions will include perimeter v-ditches and ponding areas to control all site stormwater runoff. ***The retention ponds on site do not have an outlet structure and water will drain down via infiltration or evaporate.*** Drawing P3-6 in Appendix 3C shows final drainage conditions and controls.

The final drainage conditions plan for the site entrance facilities area is provided as Drawing C-13 in Appendix 3E. Stormwater from the site entrance facilities area will be contained in one of six onsite detention areas (labeled as DA-1 through DA-6). All runoff from the site will be contained in onsite retention basins.

3B.2 Erosion and Sedimentation Controls

3B.2.1 TPDES Multi-Sector General Permit

The facility has been designed to prevent discharge of pollutants into waters of the State or waters of the United States, as defined by the Texas Water Code and the Federal Clean Water Act. An erosion and sedimentation control plan is provided in Appendix 3C, Drawing P3-11. The McCombs Landfill submitted a notice of intent (NOI) to comply with the TPDES Multi-Sector General Permit relating to stormwater discharge and received Permit No. TXR05L795 from the TCEQ on October 28, 2011. A copy of this permit is included in Appendix 2D – TPDES Multi-Sector General Permit.

3B.2.2 Best Management Practices (BMP's)

During construction phases, temporary controls will be implemented for erosion and sedimentation management. Throughout the entire phasing of construction intermediate controls will be implemented and upon final closure permanent erosion control practices will be implemented.

Structural controls may include, but are not limited to, silt fence, earthen diversion berms and dikes, drainage swales, and rip-rap. These structural controls will be implemented as follows:

- Upon final completion of Landfill development and closure, perimeter v-ditches will be constructed to divert stormwater runoff to the ponding areas shown on Drawing P3-11 - Erosion Control Plan. Ditches having velocities that exceed 4

feet per second (fps) will be protected against erosion as required by the maximum non-erodible velocities as published in the USDA-SCS Engineering Field Manual.

- When areas of the Landfill reach final design elevations, proper care will be taken to ensure that the vegetative layer is maintained to support native plant growth or that the rock cover is properly maintained. Intermediate slopes may also be vegetated depending on the length of time the area is exposed prior to commencing final grade preparations.
- In accordance with the Final Closure Plan, Section 3.8, a vegetative layer will be established upon final closure to prevent erosion. The soils used for the vegetative layer shall be evaluated for proper nutrient contact for supporting native plant life.
- Silt fence or earthen berms will be installed around stockpile areas, construction areas, or other areas of open soil to prevent sedimentation to stormwater runoff. Other BMP's as stated above may be utilized during different phases of Landfill development.
- Structural control parameters for the installation of structural controls as established in the permit revision 2 dated July 2009 by Parkhill, Smith & Cooper, Inc. in the Erosion and Sedimentation Control Plan, Table 6-E-1, are still applicable to this permit revision. The erosion and sediment control plan is provided in Appendix 3B, Attachment 6.

Non-structural controls include maintenance during daily operations at the Landfill. Any visual evidence of soil erosion shall be addressed by placing addition soil or adding/relocating structural controls. All drainage ways will be inspected for accumulation of sediment and maintained as necessary to ensure proper capacity for stormwater conveyance. The suggested inspection and maintenance schedule and the Controls Installation Schedule provided in the permit revision 2 dated July 2009 by Parkhill, Smith & Cooper, Inc. in the Erosion and Sedimentation Control Plan, Tables 6-E-2 and 6-E-3 respectively (Appendix 3B, Attachment 6), are still applicable to this permit revision. It is the Site Supervisors responsibility to ensure that these maintenance activities are completed and controls are in place and operational.

As per 30 TAC §330.305(e) the Landfill will be maintained such that:

1) *"The owner or operator shall maintain the collection, drainage, and/or storage units as designed, and shall restore and repair the drainage system in the event of washout or failure; and*
2) *The Owner or operator shall control erosion and sedimentation, including having interim controls for phased development."*

3B.3 Soil Loss Calculation

Calculations for soil loss have been performed using the Revised Universal Soil Loss Equation (RUSLE) as provided by the National Resource Conservation Service (NRCS), El Paso office. This calculation demonstrates long-term erosion stability of the Landfill and an estimation of soil loss as required by the TCEQ Solid Waste Regulations. Calculations can be seen in Appendix 3B, Attachment 5 – Closure Soil Loss Calculations. The utilized soil loss RUSLE values are provided in Appendix 3B,

Attachment 5 as well as in the Erosion and Sedimentation Control Plan completed by Parkhill, Smith & Cooper, Inc. (revision 2 dated July 2009) included in Appendix 3B, Attachment 6. It should be noted that the rainfall value "R" has been updated from previous calculations provided to the TCEQ, as it appears the value previously used was incorrect for the City of El Paso.

The soil loss calculations for final cover conditions and intermediate cover conditions are summarized below in Table 3B-1.

Table 3B-1
Soil Loss Calculation Results

Cover Conditions	Location	Cover Type	Soil Loss (tons/acre-year)[A,B]
Interim Cover	*Side Slope*	*N/A[C]*	*7.43[B]*
Intermediate Cover	*Side Slope*	*N/A[C]*	*6.48[B]*
Final Cover	*Side Slope*	*Vegetation*	*1.12[A]*
Final Cover	*Side Slope*	*Rock Cover*	*0.27[A]*
Intermediate Cover	*Top Dome*	*N/A[C]*	*~~1.01~~ 1.10[B]*
Final Cover	*Top Dome*	*Vegetation*	*~~0.17~~ 0.19[A]*
Final Cover	*Top Dome*	*Rock Cover*	*~~0.04~~ 0.05[A]*

[A] – TCEQ maximum recommended loss for final cover conditions is 2 tons/acre-year.
[B] – TCEQ maximum recommended loss for intermediate cover conditions is 50 tons/acre-year.
[C] – It is assumed that the *interim and* intermediate cover will have no ground cover.

3B.4 Non-Erodible Velocities

In accordance with 30 TAC §330.305(d)(1), estimated peak velocities for top surfaces and external embankment slopes have been compared to the permissible non-erodible velocities under similar conditions. The permissible non-erodible velocities were obtained from the Erosion and Sedimentation Control Plan by Parkhill, Smith & Cooper, Inc. (revision 2 dated July 2009) included in Appendix 3B, Attachment 6. ***Top surfaces and external embankment slopes were designed to minimize erosion and soil loss through the use of appropriate side slopes, vegetation, and other structural and non-structural controls during all phases of Landfill operation in accordance with 30 TAC §330.305(d)(2).*** Table 3B-2 provides the maximum velocity for each service compared to the permissible velocity for the cover condition. Calculations for each drainage area are provided in Appendix 3B, Attachment 7 – Drainage Calculations.

Table 3B-2
Non-Erodible Velocities

Flow Surface	Condition	Max Velocity (fps)	Max Non-Erodible Velocity (fps)	Acceptable
		Intermediate Cover		
Interim Side Slope (3:1)	*Non-Vegetated*	*1.19*	*1.5*	*Yes*
External Side Slope (3:1)	Non-Vegetated	*1.24~~1.17~~*	1.5	Yes
Top Dome (7%)	Non-Vegetated	*0.69~~0.60~~*	1.5	Yes
		Final Cover		
External Side Slope (3:1)	*Vegetated*	*1.55~~1.46~~*	*4.0*	*Yes*
Top Dome (7%)	*Vegetated*	*1.15~~1.01~~*	*4.0*	*Yes*
External Side Slope (3:1)	Rock Armored	*3.09~~2.91~~*	20	Yes
Top Dome (7%)	Rock Armored	*2.30~~2.02~~*	20	Yes
		Channels		
Channel 1	Rip Rap	4.40	20.0	Yes
Channel 2	Concrete	6.74	20.0	Yes
Channel 3	Rip Rap	4.69	20.0	Yes
Channel 4	Vegetated	3.42	4.0	Yes
Channel 5	Rip Rap	4.07	20.0	Yes

The Erosion and Sedimentation Control Plan has been developed to provide proper management and control measures for existing and developed conditions. These measures will provide management of soil erosion and control of sedimentation due to stormwater runoff.

3B.1 Drainage Conditions

The McCombs Landfill is an existing municipal solid waste disposal facility located in Section 6, Block 80, Township 1, within the city limits of El Paso, at the intersection of McCombs Road and FM 2529 (Stan Roberts Sr. Road). The site covers 327 acres and the surrounding areas are largely undeveloped. To the west of McCombs Road is the Public Service Board - El Paso Water Utilities' Sludge Monofill.

The soils in the landfill area are predominantly Turney-Berino Association, moderately deep over soft caliche, in the Hueco Bolson. The soils are characterized as moderately permeable, having high water-holding capacity, and having a slow runoff rate. Caliche covers the entire Bolson surface and ranges in thicknesses of immeasurable to 8 feet thick.

3B.1.1 Existing Conditions

The existing drainage patterns and flowrates are shown on Drawing P3-4 - Existing Drainage Conditions in Appendix 3C.

Stormwater runoff is collected in a v-ditch around the perimeter of the landfill units and is directed into an existing stormwater pond ~~on the southeastern corner~~. Runoff from north of the existing landfill is currently captured within the mined pit area. Some of the runoff in the northwest corner continues to the site of existing Retention Pond A. Runoff generated to the east is captured in the mined pit area. Runoff generated in the existing landfill areas is conveyed into existing Retention Pond D, west of the existing fee house, and existing Retention Pond E, in the southeastern corner of the developed landfill area. These exiting stormwater patterns are shown on Drawing P3-4 - Existing Drainage Conditions, in Appendix 3C.

There is an area of the landfill, including Pond A, to the northwest corner that lies within the 100-year floodplain as shown on the Flood Insurance Rate Map (FIRM) Panel No. 480214 0004 C and Appendix 3D, Drawing P3-14 – 100-Year Floodplain Map. The base flood elevations (BFE's) were converted from NGVD 29 Datum to the City of El Paso Vertical Datum with a factor provided by Land-Mark Professional Surveying Incorporated. As shown on Drawing P3-8, the BFE's are below the site berms located around the site, and therefore the 100-year flood will be diverted around the landfill site to the north and will not affect stormwater

elevations within Pond A nor will the BFE's affect landfill operations. The FIRM map is provided in Appendix 3D, Drawing P3-13.

3B.1.2 Developed Conditions

The Landfill Completion Plan is shown in Appendix 3E, Drawing P3-16 and shows all final developed conditions. The final contours include four ponds to break up drainage areas (the existing Retention Ponds A and E, and Ponds B and C), and in effect reduce sheet flow and minimize erosion. Existing Pond D is no longer needed as that area is filled to grade and flow is conveyed in a v-ditch to Pond E.

During construction, temporary diversions and drainage swales will be constructed to prevent unauthorized discharge of surface water and sediment. The final developed conditions will include perimeter v-ditches and ponding areas to control all site stormwater runoff. Drawing P3-6 in Appendix 3C shows final drainage conditions and controls.

3B.2 Erosion and Sedimentation Controls

3B.2.1 ~~NPDES Certification~~ *TPDES Multi-Sector General Permit*

The facility has been designed to prevent discharge of pollutants into waters of the State or waters of the United States, as defined by the Texas Water Code and the Federal Clean Water Act. An erosion and sedimentation control plan is provided in Appendix 3C, Drawing P3-11. The McCombs Landfill submitted a notice of intent (NOI) to comply with the ~~NPDES~~ ***TPDES Multi-Sector*** General Permit relating to stormwater discharge and received Permit No. ~~TXR05E214~~ ***TXR05L795*** from the ~~United States Environmental Protection Agency (U.S. EPA) in June of 1998~~ ***TCEQ on October 28, 2011***. A copy of this permit is included in Appendix 2D – ***TPDES Multi-Sector General Permit*** ~~NPDES Certification~~.

3B.2.2 Best Management Practices (BMP's)

During construction phases, temporary controls will be implemented for erosion and sedimentation management. Throughout the entire phasing of construction intermediate controls will be implemented and upon final closure permanent erosion control practices will be implemented.

Structural controls may include, but are not limited to, silt fence, earthen diversion berms and dikes, drainage swales, and rip-rap. These structural controls will be implemented as follows:

- Upon final completion of landfill development and closure, perimeter v-ditches will be constructed to divert stormwater runoff to the ponding areas shown on Drawing P3-11 - Erosion Control Plan. Ditches having velocities that exceed 4 feet per second (fps) will be protected against erosion ***as required by the maximum non-erodible velocities as published in the USDA-SCS Engineering Field Manual***.
- ***When areas of the landfill reach final design elevations, proper care will be taken to ensure that the vegetative layer is maintained to support native plant***

growth or that the rock cover is properly maintained. Intermediate slopes may also be vegetated depending on the length of time the area is exposed prior to commencing final grade preparations.

- In accordance with the Final Closure Plan, Section 3.8, a vegetative layer will be established upon final closure to prevent erosion. The soils used for the vegetative layer shall be evaluated for proper nutrient contact for supporting native plant life.
- Silt fence or earthen berms will be installed around stockpile areas, construction areas, or other areas of open soil to prevent sedimentation to stormwater runoff. Other BMP's as stated above may be utilized during different phases of landfill development.
- Structural control parameters for the installation of structural controls as established in the permit revision 2 dated July 2009 by Parkhill, Smith & Cooper, Inc. in the Erosion and Sedimentation Control Plan, Table 6-E-1, are still applicable to this permit revision. ***The erosion and sediment control plan is provided in Appendix 3B, Attachment 6.***

Non-structural controls include maintenance during daily operations at the landfill. Any visual evidence of soil erosion shall be addressed by placing addition soil or adding/relocating structural controls. All drainage ways will be inspected for accumulation of sediment and maintained as necessary to ensure proper capacity for stormwater conveyance. The suggested inspection and maintenance schedule and the Controls Installation Schedule provided in the permit revision 2 dated July 2009 by Parkhill, Smith & Cooper, Inc. in the Erosion and Sedimentation Control Plan, Tables 6-E-2 and 6-E-3 respectively ***(Appendix 3B, Attachment 6)***, are still applicable to this permit revision. It is the Site Supervisors responsibility to ensure that these maintenance activities are completed and controls are in place and operational.

As per 30 TAC §330.305(e) the Landfill will be maintained such that:

1) ***"The owner or operator shall maintain the collection, drainage, and/or storage units as designed, and shall restore and repair the drainage system in the event of washout or failure; and***
2) ***The Owner or operator shall control erosion and sedimentation, including having interim controls for phased development."***

3B.3 Soil Loss Calculation

Calculations for soil loss have been performed using the Revised Universal Soil Loss Equation (RUSLE) as provided by the National Resource Conservation Service (NRCS), El Paso office. This calculation demonstrates long-term erosion stability of the landfill and an estimation of soil loss as required by the TCEQ Solid Waste Regulations. Calculations can be seen in Appendix 3B, Attachment 5 – Closure Soil Loss Calculations. ***The utilized soil loss RUSLE values are provided in Appendix 3B, Attachment 5 as well as in the Erosion and Sedimentation Control Plan completed by Parkhill, Smith & Cooper, Inc. (revision 2 dated July 2009) included in Appendix 3B, Attachment 6. It should be noted that the rainfall value "R" has***

been updated from previous calculations provided to the TCEQ, as it appears the value previously used was incorrect for the City of El Paso.

The soil loss calculations for final cover conditions and intermediate cover conditions are summarized below in Table 3B-1.

Table 3B-1
Soil Loss Calculation Results

Cover Conditions	Location	Cover Type	Soil Loss (tons/acre-year)[A,B]
Final Cover	Sideslope	Vegetation	1.12
Final Cover	Sideslope	Rock Cover	0.27
Final Cover	Top Dome	Vegetation	0.17
Final Cover	Top Dome	Rock Cover	0.04
Intermediate Cover	Sideslope	N/A[C]	6.48
Intermediate Cover	Top Dome	N/A[C]	1.01

[A] – TCEQ maximum recommended loss for final cover conditions is 2 tons/acre-year.
[B] – TCEQ maximum recommended loss for intermediate cover conditions is 50 tons/acre-year.
[C] – It is assumed that the intermediate cover will have no ground cover.

3B.4 Non-Erodible Velocities

In accordance with 30 TAC §330.305(d)(1), estimated peak velocities for top surfaces and external embankment slopes have been compared to the permissible non-erodible velocities under similar conditions. The permissible non-erodible velocities were obtained from the Erosion and Sedimentation Control Plan by Parkhill, Smith & Cooper, Inc. (revision 2 dated July 2009) included in Appendix 3B, Attachment 6. Table 3B-2 provides the maximum velocity for each service compared to the permissible velocity for the cover condition. Calculations for each drainage area are provided in Appendix 3B, Attachment 7 – Drainage Calculations.

Table 3B-2
Non-Erodible Velocities

Flow Surface	*Condition*	*Max Velocity (fps)*	*Max Non-Erodible Velocity (fps)*	*Acceptable*
		Intermediate Cover		
External Sideslope (3:1)	*Non-Vegetated*	*1.17*	*1.5*	*Yes*
External Sideslope (3:1)	*Vegetated*	*1.46*	*4.0*	*Yes*
Top Dome (7%)	*Non-Vegetated*	*0.60*	*1.5*	*Yes*
Top Dome (7%)	*Vegetated*	*1.01*	*4.0*	*Yes*
		Final Cover		
External Sideslope (3:1)	*Rock Armored*	*2.91*	*20*	*Yes*
Top Dome (7%)	*Rock Armored*	*2.02*	*20*	*Yes*
		Channels		
Channel 1	*Rip Rap*	*4.40*	*20.0*	*Yes*
Channel 2	*Concrete*	*6.74*	*20.0*	*Yes*
Channel 3	*Rip Rap*	*4.69*	*20.0*	*Yes*
Channel 4	*Vegetated*	*3.42*	*4.0*	*Yes*
Channel 5	*Rip Rap*	*4.07*	*20.0*	*Yes*

REPLY TO
ATTENTION OF:

Operations Division
Regulatory Branch

Mr. Roberto Moreno, P.E.
Moreno Cardenas Inc.
2505 E. Missouri Ave.
El Paso, TX 79903

Dear Mr. Moreno:

This replies to your July 16, 2002, letter regarding the proposed expansion of McCombs Landfill in El Paso, El Paso County, Texas. We have assigned Action No. 2002 00462 to this activity.

We have evaluated the information you provided and studied the project description, other records, and documents available to us. We concur with your findings that no waters of the United States are located within the project site. There are no Corps of Engineers' jurisdictional waters on the site. Therefore, the project is not regulated under the provisions of Section 404 of the Clean Water Act and a Department of the Army permit will not be required.

Our disclaimer of jurisdiction is only for Section 404 of the Federal Clean Water Act. Other Federal, state and local laws may apply to the activities. Therefore, you should also contact other Federal, state and local regulatory authorities to determine whether the activities may require other authorizations or permits.

This jurisdictional determination will be valid for 5 years from the date of this letter unless new information warrants revision of the determination within that time.

If you have any questions, please feel free to contact me at (915) 568-1359 or e-mail me at daniel.malanchuk@usace.army.mil.

For more information about the regulatory program, please see our web site at www.spa.usace.army.mil/reg.

Sincerely,

Daniel Malanchuk
Chief, El Paso Regulatory Office

NOTES

1. MAXIMUM LENGTHS FOR EACH DRAINAGE AREA (DEV) FOR BOTH THE TOP DOME AND SIDE SLOPE ARE INDICATED ON THE DRAWING. THE SELECTED MAXIMUM LENGTH UTILIZED IN THE SOIL LOSS CALCULATIONS IS INDICATED BY THE LEGEND BELOW. THE MAXIMUM DRAINAGE LENGTH IS SELECTED TO PORTRAY THE SOIL LOSS VALUES AS IT IS THE MOST CONSERVATIVE FOR ALL DRAINAGE AREAS.

[1] Assumes a random distribution of cover types over the entire area of evaluation. Idle land refers to land with a soil profile that has not been disturbed for at least 3 consecutive years.

[2] Expresses the effectiveness of the vegetative canopy in reducing the energy of rainfall striking the soil surface.

[3] Average fall height of water droplets from the canopy to the soil surface or ground cover.

[4] Portion of total area of the surface that would be hidden from view by the canopy in an overhead projection.

[5] Portion of vegetation, mulch, cryptogams, rocks and other non-erodible material that is in direct contact with the soil surface. Affects erosion by reducing the transport capacity of runoff water by causing deposition.

Appendix 3B – Attachment 6
Drainage Calculations

SAIC®

McCombs Landfill
MSW Permit No. 729B Major Permit Amendment
Non-Erodible Velocities - Equations

T_c = Time of Concentration (minutes)
Calculated using the Watershed Lag Method in the National Engineering Handbook §630.1502
$= (L / 0.6) \times 60$

L = Lag Time (hours)
$= /^{0.8} (S + 1)^{0.7} / 1900 \times Y^{0.5}$

S = Potential Maximum Retention (inches)
$= (1000 / CN) - 10$

Y = Average Land Slope (%)

/ = Hydraulic Length of Watershed (feet)

CN = Curve Number

I_{25} = 25-year Intensity (in/hr)
$= b / (T_c + d)^e$

e_{25}*	0.843
b_{25}*	60
d_{25}*	12

*e, b, and d coeffients are provided in the Hydrology section of the Hydraulic Design Manual for Texas counties for various frequencies and are based on the rainfall-frequency-duration data contained in the National Weather Service Technical Paper 40 (TP 40)

V_{25} = 25-year Volume (ac-ft)
$= C \times I_{25}$

Calculation by:	JSR	11/02/12
Checked by:	FJD	11/02/12

DETAIL 1

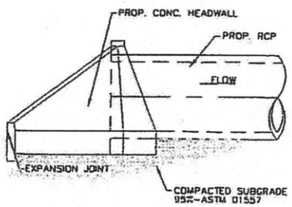
TYPICAL PERIMETER STORMWATER DITCH
SCALE: 1/2"=1'-0"

NOTES

1. DETAILS PROVIDED IN PREVIOUS PERMIT, DATED APRIL 2002, BY MORENO CARDENAS, INC. SIGNED BY ROBERTO MORENO, P.E.
2. SEE P3-10 FOR ADDITIONAL TYPICAL HEADWALL DETAILS.
3. SEE P3-6 FOR SUGGESTED CHANNEL LINING AND APPENDIX 3B FOR DITCH SIZING CALCULATIONS.

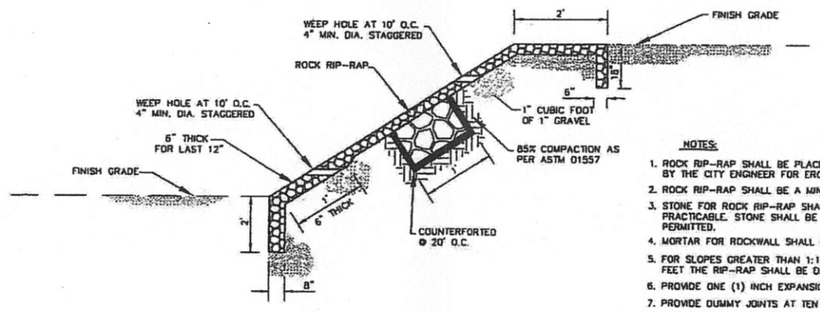
LEGEND

- COMPACTED NATIVE SOIL
- PROTECTIVE SOIL DRAINAGE MATERIAL OR BUFFER MATERIAL
- TOPSOIL
- DAILY/INTERMEDIATE COVER
- EROSION LAYER
- INFILTRATION LAYER
- REFUSE
- AGGREGATE BACKFILL
- 40 MIL LLDPE GEOMEMBRANE LINER
- GEOSYNTHETIC CLAY LINER (GCL)
- RIPRAP



DETAIL 2

TYPICAL HEADWALL DETAIL
SCALE: N.T.S.
SEE NOTES 1 AND 2



NOTES:

1. ROCK RIP-RAP SHALL BE PLACED ON EMBANKMENTS OR SLOPES WHERE REQUIRED BY THE CITY ENGINEER FOR EROSION PROTECTION, EXCEPT FOR PONDING AREAS.
2. ROCK RIP-RAP SHALL BE A MINIMUM OF 8" MORTARED ROCK.
3. STONE FOR ROCK RIP-RAP SHALL BE AS NEARLY UNIFORM IN SECTION AS IN PRACTICABLE. STONE SHALL BE QUARRIED; FRACTURED RIVER ROCK SHALL NOT BE PERMITTED.
4. MORTAR FOR ROCKWALL SHALL BE TYPE S, 1800 P.S.I. AS PER ASTM C270.
5. FOR SLOPES GREATER THAN 1:1 OR VERTICAL HEIGHT OF MORE THAN SIX (6) FEET THE RIP-RAP SHALL BE DESIGNED BY A PROFESSIONAL ENGINEER.
6. PROVIDE ONE (1) INCH EXPANSION JOINT AT EVERY FIFTY (50) FEET.
7. PROVIDE DUMMY JOINTS AT TEN (10) FEET O.C.
8. NON-MORTARED ROCK RIP-RAP SHALL BE ALLOWED WHERE APPROVED BY DEPUTY DIRECTOR FOR ENGINEERING.

BARS V

GENERAL NOTES:
DESIGNED ACCORDING TO CURRENT AASHTO STANDARD AND INTERIM SPECIFICATIONS.
REINFORCING STEEL SHALL BE PLACED WITH THE CENTER OF THE OUTSIDE LAYER OF BARS 2" FROM THE SURFACE OF THE CONCRETE.
ALL REINFORCING STEEL SHALL BE GRADE 60.
ALL CONCRETE SHALL BE CLASS "C" AND SHALL HAVE A MINIMUM 28 DAY COMPRESSIVE STRENGTH OF 3600 PSI.

NOTES

1. DETAILS PROVIDED IN PREVIOUS PERMIT, DATED APRIL 2002, BY MORENO CARBENAS, INC. SIGNED BY ROBERTO MORENO, P.E.
2. THE LOCATION OF THIS HEADWALL IS SHOWN ON P3-6. THE CULVERTS WILL DISCHARGE WATER FROM THE EXISTING RETENTION POND TO STORMWATER RETENTION POND C.

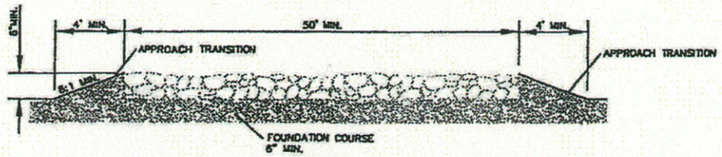
PLAN

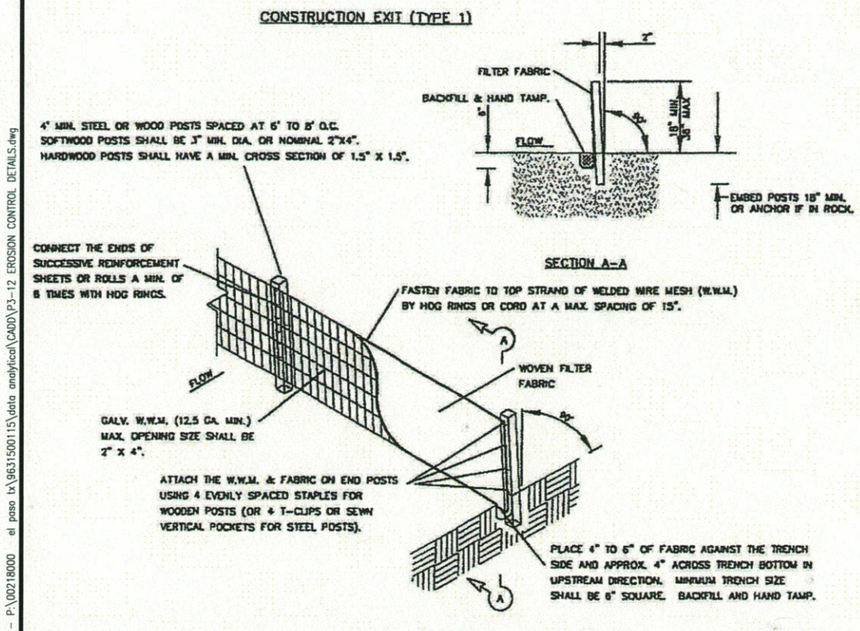


PROFILE

GENERAL NOTES

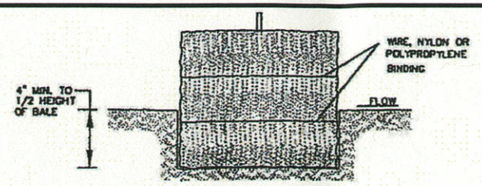
1. THE LENGTH OF THE TYPE 1 CONSTRUCTION EXIT SHALL BE AS INDICATED ON THE PLANS, BUT NOT LESS THAN 50'.
2. THE COARSE AGGREGATE SHOULD BE OPEN GRADED WITH A SIZE OF 4" TO 8".
3. THE APPROACH TRANSITIONS SHOULD BE NO STEEPER THAN 6:1 AND CONSTRUCTED AS DIRECTED BY THE ENGINEER.
4. THE CONSTRUCTION EXIT FOUNDATION COURSE SHALL BE FLEXIBLE BASE, BITUMINOUS CONCRETE, PORTLAND CEMENT CONCRETE OR OTHER MATERIAL AS APPROVED BY THE ENGINEER.
5. THE CONSTRUCTION EXIT SHALL BE GRADED TO ALLOW DRAINAGE TO A SEDIMENT TRAPPING DEVICE.
6. THE GUIDELINES SHOWN HEREON ARE SUGGESTIONS ONLY AND MAY BE MODIFIED BY THE ENGINEER.

CONSTRUCTION EXIT (TYPE 1)

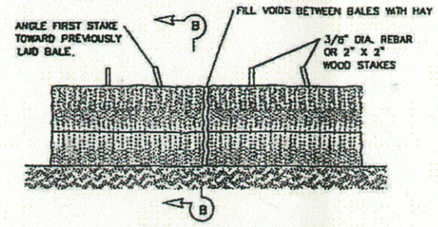


SECTION A-A

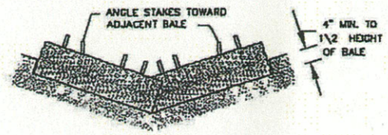
TEMPORARY SEDIMENT CONTROL FENCE



SECTION B-B



BALED HAY FOR EROSION CONTROL



PROFILE VIEW

BALED HAY USAGE GUIDELINES

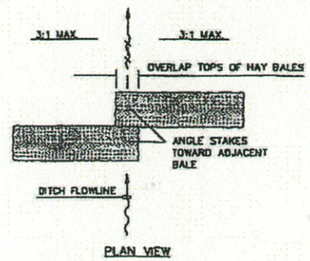
A BALED HAY INSTALLATION MAY BE CONSTRUCTED NEAR THE DOWNSTREAM PERIMETER OF A DISTURBED AREA ALONG A CONTOUR TO INTERCEPT SEDIMENT FROM OVERLAND RUNOFF. A TWO YEAR STORM FREQUENCY MAY BE USED TO CALCULATE THE FLOW RATE TO BE FILTERED. THE INSTALLATION SHOULD BE SIZED TO FILTER A MAXIMUM FLOW THRU RATE OF 5 GPM/FT^2 OF CROSS SECTIONAL AREA. BALED HAY MAY BE USED AT THE FOLLOWING LOCATIONS:

1. WHERE THE RUNOFF APPROACHING THE BALED HAY FLOWS OVER DISTURBED SOIL FOR LESS THAN 100'. IF THE SLOPE OF THE DISTURBED SOIL EXCEEDS 10%, THE LENGTH OF SLOPE UPSTREAM THE BALED HAY SHOULD BE LESS THAN 50'.
2. WHERE THE INSTALLATION WILL BE REQUIRED FOR LESS THAN 3 MONTHS.
3. WHERE THE CONTRIBUTING DRAINAGE AREA IS LESS THAN 1/2 ACRE.

FOR BALED HAY INSTALLATIONS IN SMALL DITCHES, THE ADDITIONAL FOLLOWING CONSIDERATIONS APPLY:

1. THE DITCH SIDESLOPES SHOULD BE GRADED AS FLAT AS POSSIBLE TO MAXIMIZE THE DRAINAGE FLOWRATE THRU THE HAY.
2. THE DITCH SHOULD BE GRADED LARGE ENOUGH TO CONTAIN THE OVERTOPPING DRAINAGE WHEN SEDIMENT HAS FILLED TO THE TOP OF THE BALED HAY.

BALES SHOULD BE REPLACED USUALLY EVERY 2 MONTHS OR MORE OFTEN DURING WET WEATHER WHEN LOSS OF STRUCTURAL INTEGRITY IS ACCELERATED.



PLAN VIEW

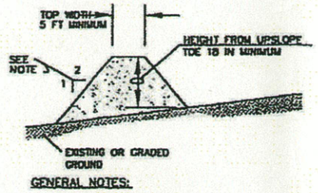
GENERAL NOTES

1. HAY BALES SHALL BE A MINIMUM OF 36" IN LENGTH AND WEIGH A MINIMUM OF 50 LBS.
2. HAY BALES SHALL BE BOUND BY EITHER WIRE OR NYLON OR POLYPROPYLENE STRING. THE BALES SHALL BE COMPOSED ENTIRELY OF VEGETABLE MATTER.
3. HAY BALES SHALL BE EMBEDDED IN THE SOIL A MINIMUM OF 4" AND WHERE POSSIBLE 1/2 THE HEIGHT OF THE BALE.
4. HAY BALES SHALL BE PLACED IN A ROW WITH ENDS TIGHTLY ABUTTING THE ADJACENT BALES. THE BALES SHALL BE PLACED WITH BINDINGS PARALLEL TO THE GROUND.
5. HAY BALES SHALL BE SECURELY ANCHORED IN PLACE WITH 3/8" DIA. REBAR OR 2" X 2" WOOD STAKES, DRIVEN THROUGH THE BALES. THE FIRST STAKE SHALL BE ANGLED TOWARDS THE PREVIOUSLY LAID BALE TO FORCE THE BALES TOGETHER.
6. THE GUIDELINES SHOWN HEREON ARE SUGGESTIONS ONLY AND MAY BE MODIFIED BY THE ENGINEER.

BALED HAY FOR EROSION CONTROL

NOTES

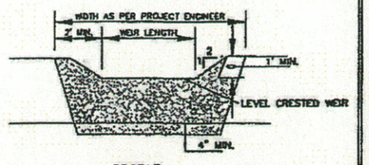
1. DETAILS PROVIDED IN PREVIOUS PERMIT, DATED APRIL 2002, BY MORENO CARDENAS, INC., SIGNED BY ROBERTO MORENO, P.E.



GENERAL NOTES:

1. SOIL USED IN BERM CONSTRUCTION SHALL BE MACHINE COMPACTED.
2. TOP WIDTH AND HEIGHT OF BERM MAY BE MODIFIED WITH PRIOR APPROVAL OF THE ENGINEER.
3. SIDE SLOPES WITHIN THE SAFETY CLEAR ZONE OF A ROADWAY SHALL BE 6:1 OR FLATTER.
4. GRADING SHALL BE SHOWN ELSEWHERE IN THE PLANS OR AS DIRECTED BY THE ENGINEER.
5. THE ENGINEER RESERVES THE RIGHT TO MODIFY THE DIMENSIONS SHOWN FOR THE BERM DEPENDENT ON RUNOFF VOLUME CHARACTERISTICS.
6. BERM THAT ARE IN PLACE FOR MORE THAN 14 CALENDAR DAYS SHOULD BE STABILIZED TO PREVENT SEDIMENT RUNOFF.
7. THE GUIDELINES SHOWN HEREON ARE SUGGESTIONS ONLY AND MAY BE MODIFIED BY THE ENGINEER.

TYPICAL BERM CONFIGURATION



PROFILE

ROCK FILTER DAM USAGE GUIDELINES

ROCK FILTER DAMS SHOULD BE CONSTRUCTED DOWNSTREAM FROM DISTURBED AREAS TO INTERCEPT SEDIMENT FROM OVERLAND RUNOFF AND/OR CONCENTRATED FLOW. THE DAMS SHOULD BE SIZED TO FILTER A MAXIMUM FLOW THROUGH RATE OF 40 GPM/FT^2 OF CROSS SECTIONAL AREA. A 2 YEAR STORM FREQUENCY MAY BE USED TO CALCULATE THE FLOW RATE.

TYPE 1 (18" HIGH WITH NO WIRE MESH): TYPE 1 MAY BE USED AT THE TOE OF SLOPES, AROUND INLETS, IN SMALL DITCHES, AND AT DIKE OR SWALE OUTLETS. THIS TYPE OF DAM IS RECOMMENDED TO CONTROL EROSION FROM A DRAINAGE AREA OF 5 ACRES OR LESS. TYPE 1 MAY NOT BE USED IN CONCENTRATED HIGH VELOCITY FLOWS (APPROX. 8 FT/SEC OR MORE) IN WHICH AGGREGATE WASH OUT MAY OCCUR. SANDBAGS MAY BE USED AT THE EMBEDDED FOUNDATION (4" DEEP MIN.) FOR BETTER FILTERING EFFICIENCY OF LOW FLOWS IF CALLED FOR ON THE PLANS OR DIRECTED BY THE ENGINEER.

TYPE 2 (18" HIGH WITH WIRE MESH): TYPE 2 MAY BE USED IN DITCHES AND AT DIKE OR SWALE OUTLETS.

TYPE 3 (36" HIGH WITH WIRE MESH): TYPE 3 MAY BE USED IN STREAM FLOW AND SHOULD BE SECURED TO THE STREAM BED.

TYPE 4 (SACK GABIONS): TYPE 4 MAY BE USED IN DITCHES AND SMALLER CHANNELS TO FORM AN EROSION CONTROL DAM.

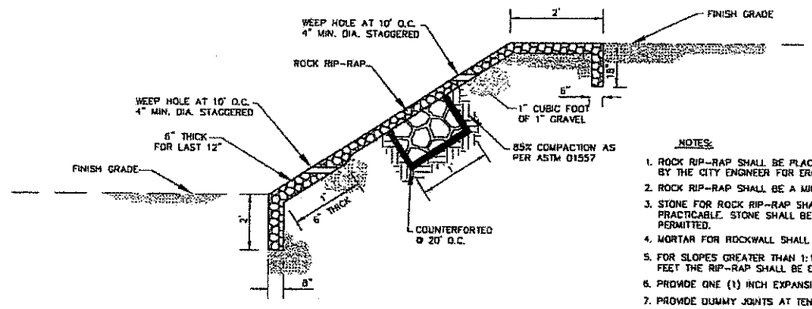
DETAIL 2

TYPICAL HEADWALL DETAIL
SCALE: N.T.S.
SEE NOTES 1 AND 2



NOTES:

1. ROCK RIP-RAP SHALL BE PLACED ON EMBANKMENTS OR SLOPES WHERE REQUIRED BY THE CITY ENGINEER FOR EROSION PROTECTION, EXCEPT FOR PONDING AREAS.
2. ROCK RIP-RAP SHALL BE A MINIMUM OF 8" MORTARED ROCK.
3. STONE FOR ROCK RIP-RAP SHALL BE AS NEARLY UNIFORM IN SECTION AS IN PRACTICABLE. STONE SHALL BE QUARRIED; FRACTURED RIVER ROCK SHALL NOT BE PERMITTED.
4. MORTAR FOR ROCKWALL SHALL BE TYPE S, 1800 P.S.I. AS PER ASTM C270.
5. FOR SLOPES GREATER THAN 1:1 OR VERTICAL HEIGHT OF MORE THAN SIX (6) FEET THE RIP-RAP SHALL BE DESIGNED BY A PROFESSIONAL ENGINEER.
6. PROVIDE ONE (1) INCH EXPANSION JOINT AT EVERY FIFTY (50) FEET.
7. PROVIDE DUMMY JOINTS AT TEN (10) FEET O.C.
8. NON-MORTARED ROCK RIP-RAP SHALL BE ALLOWED WHERE APPROVED BY DEPUTY DIRECTOR FOR ENGINEERING.

KEY TO MAP

500-Year Flood Boundary	ZONE B
100-Year Flood Boundary	ZONE A1 ZONE A3
Zone Designations*	ZONE B
100-Year Flood Boundary	ZONE C
500-Year Flood Boundary	
Base Flood Elevation Line With Elevation in Feet**	513
Base Flood Elevation in Feet Where Uniform Within Zone**	(EL 987)
Elevation Reference Mark	RM7x
Zone D Boundary	
River Mile	RM15

**Referenced to the National Geodetic Vertical Datum of 1929

*EXPLANATION OF ZONE DESIGNATIONS

ZONE	EXPLANATION
A	Areas of 100-year flood; base flood elevations and flood hazard factors not determined.
AO	Areas of 100-year shallow flooding where depths are between one (1) and three (3) feet; average depths of inundation are shown, but no flood hazard factors are determined.
AH	Areas of 100-year shallow flooding where depths are between one (1) and three (3) feet; base flood elevations are shown, but no flood hazard factors are determined.
A1-A30	Areas of 100-year flood; base flood elevations and flood hazard factors determined.
A99	Areas of 100-year flood to be protected by flood protection system under construction; base flood elevations and flood hazard factors not determined.
B	Areas between limits of the 100-year flood and 500-year flood; or certain areas subject to 100-year flooding with average depths less than one (1) foot or where the contributing drainage area is less than one square mile; or areas protected by levees from the base flood. (Medium shading)
C	Areas of minimal flooding. (No shading)
D	Areas of undetermined, but possible, flood hazards.
V	Areas of 100-year coastal flood with velocity (wave action); base flood elevations and flood hazard factors not determined.
V1-V30	Areas of 100-year coastal flood with velocity (wave action); base flood elevations and flood hazard factors determined.

NOTES TO USER

Certain areas not in the special flood hazard areas (Zones A and V) may be protected by flood control structures.

This map is for use in administering the National Flood Insurance Program; it does not necessarily identify all areas subject to flooding, particularly from local drainage sources of small size, or all planimetric features outside special flood hazard areas. The coastal flooding elevations shown were derived from those developed by the National Weather Service for hurricane evacuation planning.

For adjoining map panels, see separately printed Index to Map Panels.

INITIAL IDENTIFICATION:
NOVEMBER 15, 1979

FLOOD HAZARD BOUNDARY MAP REVISIONS:
NONE

FLOOD INSURANCE RATE MAP EFFECTIVE:
OCTOBER 15, 1987

FLOOD INSURANCE RATE MAP REVISED:
JUNE 15, 1988 - Revised to reflect results of detailed flood studies, to add special flood hazard areas, to add additional flood boundaries, to change special flood hazard areas and to change some zone designations

For information on flood insurance for this community, contact your insurance agent or call the National Flood Insurance Program at (800) 638-6620.

**Referenced to the National Geodetic Vertical Datum of 1929

*EXPLANATION OF ZONE DESIGNATIONS

ZONE	EXPLANATION
A	Areas of 100-year flood; base flood elevations and flood hazard factors not determined.
AO	Areas of 100-year shallow flooding where depths are between one (1) and three (3) feet; average depths of inundation are shown, but no flood hazard factors are determined.
AH	Areas of 100-year shallow flooding where depths are between one (1) and three (3) feet; base flood elevations are shown, but no flood hazard factors are determined.
A1-A30	Areas of 100-year flood; base flood elevations and flood hazard factors determined.
A99	Areas of 100-year flood to be protected by flood protection system under construction; base flood elevations and flood hazard factors not determined.
B	Areas between limits of the 100-year flood and 500-year flood; or certain areas subject to 100-year flooding with average depths less than one foot or where the contributing drainage area is less than one square mile; or areas protected by levees from the base flood. (Medium shading)
C	Areas of minimal flooding. (No shading)
D	Areas of undetermined, but possible, flood hazards
V	Areas of 100-year coastal flood with velocity (wave action); base flood elevations and flood hazard factors not determined.
V1-V30	Areas of 100-year coastal flood with velocity (wave action); base flood elevations and flood hazard factors determined.

NOTES TO USER

Certain areas not in the special flood hazard areas (zones A and V) may be protected by flood control structures.

This map is for use in administering the National Flood Insurance Program; it does not necessarily identify all areas subject to flooding, particularly from local drainage sources of small size, or all planimetric features outside special flood hazard areas. The coastal flooding elevations shown may differ significantly from those developed by the National Weather Service for hurricane evacuation planning.

For adjoining map panels, see separately printed Index to Map Panels.

Memorandum

To: TCEQ

From: Cami Van Abel, P.E.

Subject: Appendix 3E, Sheet C13

Date: March 15, 2013

Sheet C13 prepared by Moreno Cardenas and dated October 22, 2012 is provided to provide the drainage area runoff computations and retention pond computations for the site facility improvements. The calculations provided are current to the site facility improvements.

NOTES

1. CONTOURS SHOWN REPRESENT TOP OF COMPACTED NATIVE SUBGRADE SOIL IN FUTURE CELLS OR INTERIM COVER SOIL IN EXISTING CELLS.
2. BASE CONTOUR INTERVAL FOR SOLID CONTOURS IS FIVE FEET. BASE CONTOUR INTERVAL FOR DASHED CONTOURS IS ONE FOOT. ELEVATIONS ARE CITY OF EL PASO VERTICAL DATUM.
3. INTERIOR SECTOR BOUNDARY LOCATIONS FOR SECTORS B, D, E, AND F ARE CONSIDERED TO BE A MOVING TARGET AND MAY VARY DEPENDING ON THE AMOUNT OF FILL ON THE EXISTING UNLINED LANDFILL AT THE TIME OF CELL DEVELOPMENT. CURRENT INTERIOR SECTOR BOUNDARIES ARE BASED ON EXISTING CONDITIONS AS OF FEBRUARY 2011.
4. SECTOR A THROUGH J WILL BE UTILIZED FOR MUNICIPAL SOLID WASTE PLACEMENT. SECTOR K WILL BE UTILIZED FOR CONTINUED MSW/ASBESTOS PLACEMENT DURING SITE DEVELOPMENT.

NOTES

1. CONTOURS SHOWN REPRESENT TOP OF COMPACTED NATIVE SUBGRADE SOIL IN FUTURE CELLS OR INTERIM COVER SOIL IN EXISTING CELLS.
2. BASE CONTOUR INTERVAL FOR SOLID CONTOURS IS FIVE FEET. BASE CONTOUR INTERVAL FOR DASHED CONTOURS IS ONE FOOT. ELEVATIONS ARE CITY OF EL PASO VERTICAL DATUM.
3. INTERIOR SECTOR BOUNDARY LOCATIONS FOR SECTORS B, D, E, AND F ARE CONSIDERED TO BE A MOVING TARGET AND MAY VARY DEPENDING ON THE AMOUNT OF FILL ON THE EXISTING UNLINED LANDFILL AT THE TIME OF CELL DEVELOPMENT. CURRENT INTERIOR SECTOR BOUNDARIES ARE BASED ON EXISTING CONDITIONS AS OF FEBRUARY 2011.
4. SECTOR A THROUGH J WILL BE UTILIZED FOR MUNICIPAL SOLID WASTE PLACEMENT. SECTOR K WILL BE UTILIZED FOR CONTINUED MSW/ASBESTOS PLACEMENT DURING SITE DEVELOPMENT.

SHT. 51 OF 78
DRAWING NUMBER: P3–18

Keller, Tonya L. 10/22/2012 9:32:22 AM – P:\00216000 el paso tx\9631500115\data analytical\CADD\P3-18 SECTION LAYOUT PLAN.dwg

NOTES

1. CONTOURS PROVIDED WITHIN LANDFILL BOUNDARY REPRESENT TOP OF FINAL CONTOURS. CONTOUR INTERVAL IS TEN FEET
2. DIGITIZED TOPOGRAPHY FROM AERIAL SURVEY COMPLETED IN FEBRUARY 2011 BY COOPER AERIAL SURVEYS COMPANY, TUCSON, AZ. TOPOGRAPHY PROVIDED BY FRANK X. SPENSER & ASSOCIATES, INC., EL PASO, TEXAS. EXISTING CONTOUR INTERVAL IS TWO FEET.
3. COORDINATES ARE BASED ON THE TEXAS STATE PLANE COORDINATE SYSTEM, CENTRAL ZONE, NAD 83. ELEVATIONS ARE ~~NAVD 88~~ CITY OF EL PASO VERTICAL DATUM. NAVD 88 DATUM TO NGVD 29 DATUM, SUBTRACT 1.99–FEET. NGVD 29 DATUM TO CITY OF EL PASO DATUM, ADD 27.65–FEET

HORIZONTAL SCALE: 1" = 200'

D P3-18 D P3-26

NOTES

1. EXISTING GRADE FROM AERIAL SURVEY COMPLETED IN FEBRUARY 2011 BY COOPER AERIAL SURVEYS COMPANY, TUCSON, AZ. TOPOGRAPHY PROVIDED BY FRANK X. SPENSER & ASSOCIATES, INC., EL PASO, TEXAS.
2. EXISTING UNLINED AND LINED BASE CONTOURS OBTAINED FROM DRA CONSULTANTS APPLICATION FOR PERMIT AMENDMENT NO. 729, ATTACHMENT NO. 11, SHEET A1, DATED APRIL 1983.
3. ACTUAL WASTE ELEVATIONS WILL BE DEPENDENT ON THE FINAL COVER PROFILE UTILIZED (I.E., PRESCRIPTIVE OR ALTERNATIVE FINAL COVER), BUT WILL GENERALLY BE 40 OR 48-INCHES LOWER THAN THE FINAL CONTOUR ELEVATIONS (REFER TO DETAILS).
4. TYPICAL GAS WELL LOCATIONS AND CROSS SECTIONS ARE PROVIDED ON P3-39 THROUGH P3-44 IN APPENDIX 3M, ATTACHMENT 3.
5. REFER TO DRAWING P3-37 FOR APPROXIMATE GROUND WATER ELEVATIONS (LOCATED APPROXIMATELY 340-FEET BELOW LANDFILL BASE). REFER TO APPENDIX L FOR REMAINDER OF WELL BORING LOG.
6. PREVIOIUSLY APPROVED PERMITTED CONTOURS SUBMITTED TO THE TNRCC BY MORENO CARDENAS FOR THE 2002 APPLICATION FOR PERMIT AMENDMENT NO. 729A.

SAIC®

Memorandum

SAIC

To: City of El Paso

From: Fred J. Doran, P.E., SAIC

Subject: AET Report of Waste Mass Stability

Date: November 22, 2011

Attached is a copy of the Report of Waste Mass Stability prepared by American Engineering Testing, Inc. (AET), dated June 1, 2011. The report was developed to:

- Estimate compression of the waste within the existing landfill due to construction of the vertical expansion;
- Recommend geosynthetic reinforcement requirements to be incorporated into the cover design at the base of the vertical landfill construction; and
- Perform waste mass stability analyses of the new landfill construction.

It should be noted that when determining the settlement of the existing waste, AET estimated that the age of the existing in place waste was 8 years old. This number was used as the last waste placed within the area was approximately 8 years ago. This assumption of the waste age is very conservative, as a large portion of the waste would be older than 8 years, and therefore will have gone through more settlement prior to placement of the new waste. Additionally, AET assumed that the C&D waste placed prior to MSW was all new waste, and did not consider the C&D as a surcharge in their analyses. This is also a conservative way to do the analyses. Using the two above conservative assumptions, AET estimated that the existing waste would settle anywhere from 5.5 – 17.6 feet (Appendix B of the AET report).

Based on AET's findings, they recommend using two layers of uniaxial geogrid placed perpendicular to each other for the geosynthetic reinforcement on top of the existing waste mass. The suggested product is a Fortrac 80MP (see attached for a specification sheet). Additionally, AET recommends a minimum of 6 inches of sand to underlay the geogrid.

For the waste mass stability, AET "anticipates that the planned landfill configuration should be stable, provided that no excess pore pressures are generated within the waste or that there is no increase in piezometric head above 1 foot within the underlying sand liner cover."

HUESKER
Engineering with Geosynthetics

Fortrac® 80MP

Huesker's Fortrac 80MP geogrid is comprised of high tenacity polyvinyl alcohol (PVA) yarns crafted into a stable interlocked pattern then coated for protection from installation damage and short term ultraviolet exposure. Fortrac geogrids are easy to install, unaffected by freeze-thaw conditions and naturally occurring chemical/biological environments. Fortrac is utilized as a tensile element in retaining wall, steepened slope and void bridging applications. Fortrac geogrids are produced at Huesker's manufacturing facility which has achieved ISO 9001 approval for its systematic approach to quality in development, manufacture, inspection, sales and application support for geosynthetic materials. Huesker's ISO 9001 certificate is available upon request.

1.0 INTRODUCTION

This report presents the results of our geotechnical review concerning waste mass stability, settlement predictions, and reinforcement recommendations for the landfill expansion of the McCombs Landfill near El Paso, Texas.

2.0 SCOPE OF SERVICES

AET's services were performed according to your Purchase Order Number P500115201, dated May 12, 2011. The authorized scope consists of the following:

- Estimate compression of the waste within the existing landfill due to construction of the new vertical expansion.
- Recommend geosynthetic reinforcement requirements to be incorporated into the cover design at the base of the vertical landfill construction
- Perform waste mass stability analyses of the new landfill construction.

3.0 PROJECT INFORMATION

The McCombs Landfill is planning to expand the existing municipal solid waste (MSW) landfill. The existing landfill has not received any new MSW since 2003. The landfill expansion will have dimensions of approximately 4,200 feet (north-south) and 2,900 feet (east-west). The new waste will be piggybacked onto the existing MSW refuse. Prior to receiving the MSW refuse, an approximately 25-foot to 55-foot thickness of construction and demolition (C&D) debris will be placed over the existing MSW waste. The maximum final landfill height will be about 270 feet above the proposed subgrade elevation, with a maximum thickness of new MSW/new C&D refuse above the existing MSW refuse on the order of 190 feet. The final landfill side slopes will be at a maximum of 3(H):1(V).

Project information for the specific analyses we performed are presented in the following sections. The stated information represents our understanding of the proposed construction. This information is an integral part of our engineering review. It is important that you contact us if there are changes from that described so that we can evaluate whether modifications to our recommendations are appropriate.

4.0 VERTICAL LANDFILL EXPANSION

4.1 Settlement of Existing Waste

According to conventional consolidation theory, the area-wide compression settlement of municipal solid waste (MSW) when subjected to the weight of the vertical expansion can be the total of two components: primary settlement and secondary settlement. No specific testing was authorized to evaluate the necessary settlement properties of the waste, therefore the following parameters, based on published information (1)(2), were assumed for our calculations.

- Unit weight of new waste = 65 pcf
- Unit weight of existing waste = 65 pcf
- Modified primary compression index, C_c', of existing waste = 0.17 to 0.36
- Modified secondary compression index, C_α', of existing waste = 0.03 to 0.10
- Age of existing waste = 8 years
- Ending time of secondary settlement = 58 years

For our analyses, we used procedures described in (1), and we also used the geometry from the cross-sections presented on the following SAIC drawings:

- Drawing Number P3-22.0, Typical Landfill Section B, dated 4/13/2011.
- Drawing Number P3-25.0, Typical Landfill Section E, dated 4/13/2011.

Copies of these sections are attached. Our settlement estimates due to the compression of the existing waste from the weight of the new, overlying waste are presented in Tables B-1 and B-2 (Appendix B) for varying primary and secondary compression indices. Please note that this does not include any immediate or consolidation settlement of the foundation soils due to the weight of the overlying landfill material.

Landfill settlements can be minimized by pretreating the landfill wastes. Pretreatment could be performed by deep dynamic compaction (DDC) or by preloading by surcharge. DDC is carried out by dropping a heavy compaction weight repeatedly at each impact location which compresses the waste. It may also be possible to pre-compress (surcharge) the existing waste by temporarily stockpiling soil from the expansion on top of the existing closed landfill, if there is sufficient time and available surcharge soil. In our judgment, this could be effective in reducing some of the anticipated primary settlement, depending on the thickness of the surcharge and duration. If you elect to surcharge this area, we suggest placing settlement instrumentation on top of the existing landfill prior to surcharge fill placement. The settlement instrumentation should then be read periodically to evaluate the effectiveness of the surcharge program.

4.2 Reinforcement Design

The planned piggyback liner profile to be constructed over the top of the C&D waste will consist of (from bottom upwards) 36 inches of compacted clay "buffer soil," a 6-inch thickness of compacted clay "interim cover soil," a geogrid stabilization layer, a geosynthetic clay liner (GCL), a 60 mil HDPE geomembrane, and 2 feet of drainage sand. The municipal solid waste (MSW) will be placed directly on the sand layer.

Our design of the geosynthetic reinforcement follows the procedure described in (1), and is

based on the scenario that a void develops, or is located, immediately underneath the liner. The liner is then assumed to bridge over the void, carrying the load from the proposed overlying waste. The "rusted refrigerator" scenario is used, with the design depression having a radius of 3 feet. Other assumptions are listed below and in Tables 4.2-1 and 4.2-2.

- Design life of 50 years
- Maximum height of MSW on the lining system is 190 feet

TABLE 4.2-1 ASSUMED MATERIAL PROPERTIES

Material	Unit Weight (pcf)	Friction Angle (deg.)	Cohesion (psf)
MSW	65	25	0
Bedding Sand	120	30	0

TABLE 4.2-2 ASSUMED GEOSYNTHETIC PROPERTIES

Material	Yield Strain (%)
HDPE	10%
GCL	8%

Based on our analyses, we recommend that the geosynthetic reinforcement consist of two layers of chemically resistant uniaxial geogrid placed perpendicular to each other. The geogrid should have a minimum design tensile strength of 3500 pounds per foot at an allowable stress of 5%, or less over the 50 year design life. The geogrid should be placed on top of a minimum 6 inch thick bedding layer of free-draining sand placed between the existing clay cap and the new GCL. Based on our conversations with a representative of Huesker (Tel. 1-512-266-3790), a geogrid such as Fortrac® 80MP would be suitable in this application. Please note that the inclusion of geogrid reinforcement is intended to reduce, but not eliminate, the probability of failure.

5.0 WASTE MASS STABILITY

5.1 Background Information

The liner system for the new expansion will consist of a 6-inch thick layer of compacted native soil covered by a 6-inch thick compacted caliche layer or as an alternative, a geosynthetic clay liner (GCL). A 60 mil HDPE geomembrane will be placed on the GCL, and will be anchored within trenches at the top of the slope. The geomembrane will be textured on both sides. A 2-foot thick sand layer will be placed over the HDPE geomembrane.

We evaluated the deep-seated stability of the waste by performing two-dimensional, effective stress slope stability analyses for the final, closed geometry, using the computer program GSLOPE Version 5.10. This program performs a limit equilibrium analysis for potential mass failure along assumed failure surfaces. For our analyses, we assumed potential failure of the waste material occurring within the waste or along the top of the HDPE liner for the deep-seated failures. Our scope does not included analyzing potential failure of, or through the HDPE liner, through the C&D waste or existing waste, the adequacy of the anchor trench design system, or stability of the underlying soil/GCL, or stability of interim slopes.

For our analyses, we used the geometry from the cross-sections presented on the following SAIC drawings:

- Drawing Number P3-21.0, "Typical Landfill Section A" dated 4/13/2011
- Drawing Number P3-22.0, "Typical Landfill Section B" dated 4/13/2011
- Drawing Number P3-25.0, "Typical Landfill Section E" dated 4/13/2011

Copies of these sections are presented in Appendix A.

5.2 Assumed Parameters

No new laboratory testing has been authorized as part of this work. The analyses are to be based on assumed or published strength and interface friction values for the sand and HDPE geomembrane. It is important that our assumed parameters are confirmed by specific testing prior to construction.

Due to the high variability of municipal waste, conventional *in situ* testing or laboratory testing to evaluate the engineering properties of the waste is not practical. Therefore, for our analyses we used published and assumed estimated effective stress values of shear strength, cohesion, and unit weight for municipal solid waste (2)(3). The engineering properties used in our analyses are presented in Table C-1 (Appendix C).

5.3 Analysis and Results

We analyzed potential circular failure surfaces and potential block or sliding failure surfaces. Our analyses assume that no more than one foot of head will develop within the sand drainage layer. We also assume that excess pore pressure will not develop within the waste either through hydrostatic pressure or gas pressure. The development of excess pore pressure would substantially reduce the factor of safety for stability. The results of our stability analyses using peak strength values are attached and are summarized in Table C-2 (Appendix C).

Due to the potential for variability of the engineering properties of the waste, we also performed a limited sensitivity analysis by evaluating the effect on the factor of safety by varying the strength parameters. The results of this limited sensitivity analysis are presented in Table C-3.

To address the potential for progressive failure, we also performed a secondary stability analysis

using assumed large displacement interface shear strengths. The results of this analysis are presented in Table C-4.

5.4 Conclusions

The calculated factor of safety for the peak displacement conditions exceeded 1.5 for our assumed strength and unit weight parameters, the analyzed cross sections, and assumed failure geometry. In addition, the calculated factor of safety for the large displacement condition exceeds 1.3, which in our judgment, and based on published information, is acceptable.

The results of the limited sensitivity analysis indicates a factor of safety of at least 1.89 with respect to deep seated wedge failure. Please note that the calculated factor of safety of 1.46 shown for the circular analyses is not for deep seated failure, but rather a reflection of potential near surface failure, and is due to the lack of cohesion in the analysis which is needed for deep seated circular failure analysis.

Based on our results, in our opinion, we anticipate that the planned landfill configuration should be stable, provided that no excess pore pressures are generated within the waste or that there is no increase in piezometric head above 1 foot within the underlying sand liner cover. The generation of pore pressures and increase in piezometric head within these materials will substantially reduce the factor of safety and increase the risk for stability problems

To reduce the potential for the development of excess pore pressures and piezometric head within the waste, we strongly recommend that the intermediate cover soils be sufficiently permeable so that as the height of the waste increases, the leachate does not become ponded on the underlying buried cover layers. That is, leachate should be allowed to permeate through the buried cover soils down to the underlying sand leachate collection system. If the permeability of

the intermediate cover soils is low and will not allow the rapid transmission of the leachate through the buried cover soils, then the intermediate cover soils should be breached by excavating trenches through the cover soils prior to continued waste placement to allow the leachate to permeate through down to the leachate collection system.

We strongly recommend that laboratory testing be performed using the specific HDPE liner material chosen for the project to confirm our assumed interface friction values used in our analyses. Additional stability analyses may also be required at that time.

6.0 LIMITATIONS

Within the limitations of scope, budget, and schedule, we have endeavored to provide our services according to generally accepted geotechnical engineering practices at this time and location. Other than this, no warranty, either express or implied, is intended.

Appendix D

Geotechnical Report Limitations and Guidelines for Use

Appendix D
Geotechnical Report Limitations and Guidelines for Use
Report No. 01-05106

B.1 REFERENCE

This appendix provides information to help you manage your risks relating to subsurface problems which are caused by construction delays, cost overruns, claims, and disputes. This information was developed and provided by ASFE[1], of which, we are a member firm.

B.2 RISK MANAGEMENT INFORMATION

B.2.1 Geotechnical Services are Performed for Specific Purposes, Persons, and Projects

Geotechnical engineers structure their services to meet the specific needs of their clients. A geotechnical engineering study conducted for a civil engineer may not fulfill the needs of a construction contractor or even another civil engineer. Because each geotechnical engineering study is unique, each geotechnical engineering report is unique, prepared solely for the client. No one except you should rely on your geotechnical engineering report without first conferring with the geotechnical engineer who prepared it. And no one, not even you, should apply the report for any purpose or project except the one originally contemplated.

B.2.2 Read the Full Report

Serious problems have occurred because those relying on a geotechnical engineering report did not read it all. Do not rely on an executive summary. Do not read selected elements only.

B.2.3 A Geotechnical Engineering Report is Based on A Unique Set of Project-Specific Factors

Geotechnical engineers consider a number of unique, project-specific factors when establishing the scope of a study. Typically factors include: the client's goals, objectives, and risk management preferences; the general nature of the structure involved, its size, and configuration; the location of the structure on the site; and other planned or existing site improvements, such as access roads, parking lots, and underground utilities. Unless the geotechnical engineer who conducted the study specifically indicates otherwise, do not rely on a geotechnical engineering report that was:

- not prepared for you,
- not prepared for your project,
- not prepared for the specific site explored, or
- completed before important project changes were made.

Typical changes that can erode the reliability of an existing geotechnical engineering report include those that affect:

- the function of the proposed structure, as when it's changed from a parking garage to an office building, or from a light industrial plant to a refrigerated warehouse,
- elevation, configuration, location, orientation, or weight of the proposed structure,
- composition of the design team, or
- project ownership.

As a general rule, always inform your geotechnical engineer of project changes, even minor ones, and request an assessment of their impact. Geotechnical engineers cannot accept responsibility or liability for problems that occur because their reports do not consider developments of which they were not informed.

B.2.4 Subsurface Conditions Can Change

A geotechnical engineering report is based on conditions that existed at the time the study was performed. Do not rely on a geotechnical engineering report whose adequacy may have been affected by: the passage of time; by man-made events, such as construction on or adjacent to the site; or by natural events, such as floods, earthquakes, or groundwater fluctuations. Always contact the geotechnical engineer before applying the report to determine if it is still reliable. A minor amount of additional testing or analysis could prevent major problems.

Telephone: 301/565-2733: www.asfe.org

B.2.5 Most Geotechnical Findings Are Professional Opinions
Site exploration identified subsurface conditions only at those points where subsurface tests are conducted or samples are taken. Geotechnical engineers review field and laboratory data and then apply their professional judgment to render an opinion about subsurface conditions throughout the site. Actual subsurface conditions may differ, sometimes significantly, from those indicated in your report. Retaining the geotechnical engineer who developed your report to provide construction observation is the most effective method of managing the risks associated with unanticipated conditions.

B.2.6 A Report's Recommendations Are Not Final
Do not overrely on the construction recommendations included in your report. Those recommendations are not final, because geotechnical engineers develop them principally from judgment and opinion. Geotechnical engineers can finalize their recommendations only by observing actual subsurface conditions revealed during construction. The geotechnical engineer who developed your report cannot assume responsibility or liability for the report's recommendations if that engineer does not perform construction observation.

B.2.7 A Geotechnical Engineering Report Is Subject to Misinterpretation
Other design team members' misinterpretation of geotechnical engineering reports has resulted in costly problems. Lower that risk by having your geotechnical engineer confer with appropriate members of the design team after submitting the report. Also retain your geotechnical engineer to review pertinent elements of the design team's plans and specifications. Contractors can also misinterpret a geotechnical engineering report. Reduce that risk by having your geotechnical engineer participate in prebid and preconstruction conferences, and by providing construction observation.

B.2.8 Do Not Redraw the Engineer's Logs
Geotechnical engineers prepare final boring and testing logs based upon their interpretation of field logs and laboratory data. To prevent errors or omissions, the logs included in a geotechnical engineering report should never be redrawn for inclusion in architectural or other design drawings. Only photographic or electronic reproduction is acceptable, but recognizes that separating logs from the report can elevate risk.

B.2.9 Give Contractors a Complete Report and Guidance
Some owners and design professionals mistakenly believe they can make contractors liable for unanticipated subsurface conditions by limiting what they provide for bid preparation. To help prevent costly problems, give contractors the complete geotechnical engineering report, but preface it with a clearly written letter of transmittal. In the letter, advise contractors that the report was not prepared for purposes of bid development and that the report's accuracy is limited; encourage them to confer with the geotechnical engineer who prepared the report (a modest fee may be required) and/or to conduct additional study to obtain the specific types of information they need or prefer. A prebid conference can also be valuable. Be sure contractors have sufficient time to perform additional study. Only then might you be in a position to give contractors the best information available to you, while requiring them to at least share some of the financial responsibilities stemming from unanticipated conditions.

B.2.10 Read Responsibility Provisions Closely
Some clients, design professionals, and contractors do not recognize that geotechnical engineering is far less exact than other engineering disciplines. This lack of understanding has created unrealistic expectations that have led to disappointments, claims, and disputes. To help reduce the risk of such outcomes, geotechnical engineers commonly include a variety of explanatory provisions in their report. Sometimes labeled "limitations" many of these provisions indicate where geotechnical engineers' responsibilities begin and end, to help others recognize their own responsibilities and risks. Read these provisions closely. Ask questions. Your geotechnical engineer should respond fully and frankly.

B.2.11 Geoenvironmental Concerns Are Not Covered
The equipment, techniques, and personnel used to perform a geoenvironmental study differ significantly from those used to perform a geotechnical study. For that reason, a geotechnical engineering report does not usually relate any geoenvironmental findings, conclusions, or recommendations; e.g., about the likelihood of encountering underground storage tanks or regulated contaminants. Unanticipated environmental problems have led to numerous project failures. If you have not yet obtained your own geoenvironmental information, ask your geotechnical consultant for risk management guidance. Do not rely on an environmental report prepared for someone else.

From: Fred J. Doran, P.E., SAIC

Subject: AET Report of Supplemental Geotechnical Evaluation and Anchor Trench Stability Calculations

Date: November 2, 2012

Attached is a copy of the Supplemental Geotechnical Evaluation prepared by American Engineering Testing, Inc. (AET), dated August 3, 2012. The report was developed to supplement the original report titled "Report of Waste Mass Stability, McCombs Landfill Expansion, El Paso, Texas". Furthermore, this report includes the following analyses and results (some results taken verbatim from the report):

- Perform a waste mass stability analysis that includes the proposed C&D waste and the existing municipal solid waste;
  - Minimum factor of safety utilizing peak strength values is greater than 1.5. Additionally, a limited sensitivity analysis was completed by varying the strength parameters. Results indicate a factor of safety ranging from 1.47 to 2.78 (acceptable).
- Perform a waste mass stability of interim slopes;
  - Waste mass stability was completed for interim slopes at a 3H:1V slope at a maximum length of 270 feet. The factor of safety using peak strength parameters was 2.64 (circular failure) and 2.42 (block failure). The factor of safety assuming large displacement strength parameters was 1.60 (circular failure) and 1.76 (block failure).
- Evaluate stability and settlement of the final cover (both prescriptive and alternative);
  - Veneer Stability for Prescriptive Cover: 1.33 with parallel seepage and 1.61 for gravity conditions only.
    - The calculations for veneer stability with a factor of safety of 1.33 were calculated using a 28° internal friction angle of the erosion layer (drainage layer consisting of sand) and a saturated depth of 0.49 feet (Appendix 3I, Attachment 2, Page 104: peak daily value for maximum head on top of layer 3 equals 5.85 inches, or 0.49 feet).
    - In order to obtain a factor of safety of 1.5, the internal friction angle of the erosion layer (drainage layer consisting of sand) needs to be 31°. Published values for the internal friction angle of sand are 26° - 40° and should be readily obtainable from the material onsite. As shown on the drawings provided in Appendix 3F – Landfill Cross Sections, the boring logs for the area consist predominately of sand. The sand onsite will be tested prior to use to ensure that the internal friction angle is 31°. In the event that the

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

friction angle is unobtainable with onsite soil, alternative off-site sources will be located to provide for an erosion layer soil with the required internal friction angle.

- Veneer Stability for Alternative Cover: 1.41 for no water flow.
  - An internal friction angle of 25° was utilized to calculate the factor of safety of 1.41.
  - An internal friction angle of 27° for the sand is required to increase the factor of safety to 1.5 for the no flow conditions. Soils testing will be completed prior to construction to ensure that the internal friction angle of the sand is at least 27° to ensure the 1.5 factor of safety (which should be readily obtainable as described above). Furthermore, it should be noted that the parallel seepage analysis completed by AET does not apply to the alternative cover system as there is no saturation depth for the alternative cover. The alternative cover is designed so that a zone of saturation will never be established as the water entering will be countered by evapotranspiration.

- Evaluate final cover settlement and strain;
  - Analyses completed in initial report. In summary, the maximum tensile strain calculated in the final cover is less than 0.01%, with most values less than zero (compression). Published information indicates that LLDPE can generally be assumed to have a yield strain on the order of 12% or more. The calculated tensile strain should not adversely affect the final cover material.
- Evaluate piggyback liner settlement and strain;
  - Analyses completed in initial report. In summary, the maximum tensile strain calculated is 0.206%. Published information indicates that HDPE can generally be assumed to have a yield strain in excess of 12% and GCL can generally be assumed to have a yield strain of 1% to 10%. The geogrid will have an allowable strain of 5%. The calculated tensile strain should not adversely affect the piggyback liner materials.
- Evaluate settlement of the foundation soils; and
  - The foundation settlement is estimated to be less than one foot, and the strain is estimated to be 0.03% or less. This amount of settlement and strain should not adversely affect the existing HDPE liner.
- Perform a preliminary review of our stability analyses with respect to seismic stability.
  - Although not required for a vertical expansion of Landfills, AET performed a preliminary review of the stability analyses with respect to seismic stability. Results are included here within.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Additionally, anchor trench stability calculations with regards to pullout and the interface liner system stability for gravity and equipment conditions were completed by SAIC and are included in Appendix 3G, Attachment 3. Results indicate the following factors of safety:

- Anchor trench pullout versus tear: 1.10
  - The anchor trench was designed with both constructability and strength in mind. The anchor trench should fail and pullout rather than the sideslope geomembrane liner failing and tearing, since it will be easier to observe and repair an anchor trench failure. However, the anchor trench also has to aid in construction, and providing a shallower anchor trench may have issues with wind and water migration under the liner edge. The calculated factor of safety of 1.1 is considered adequate as it shows that anchor trench pullout will be the governing failure mode. Also note that the configuration is temporary as the slope will be filled against after phase construction.
- Interface liner system stability (gravity): 1.37
  - The interface liner system stability calculations are also most critical during and immediately after phase construction (until waste filling begins within the phase) and are a temporary condition. As waste is filled against the slope, the waste creates a buttress to provide more strength against failure. The calculated 1.37 factor of safety is considered adequate for temporary conditions.
- Interface liner system stability (equipment): 1.31 and 1.36
  - As described above, the calculated factors of safety are for temporary conditions during phase construction and are considered adequate.

It should be noted that all construction materials should be tested prior to use to ensure compliance with these calculations. If materials do not meet the requirements specified, analysis should be recompleted for the actual material properties.

All recommendations within the AET Report dated August 3, 2012 will be implemented in full upon permit amendment approval.

Attn: Mr. Fred Doran, PE

RE: Supplemental Geotechnical Evaluation
McCombs Landfill Expansion
El Paso, Texas
AET Report No. 01-05106

Dear Mr. Doran:

This report presents the results of our supplemental geotechnical evaluation for the referenced project. We are submitting an electronic copy and three hard copies of the report to you. This work was performed in accordance with our proposal to you dated May 2, 2012, which was authorized by your Purchase Order No. P500115201, dated May 12, 2012. This report is a supplement to our original report to you titled *Report of Waste Mass Stability, McCombs Landfill Expansion, El Paso, Texas*, dated June 1, 2011, and addresses comments you received from the Texas Commission on Environmental Quality (TCEQ).

1.0 Scope of Supplemental Services

Our scope of services for this supplemental evaluation consists of the following items:

1. Perform a waste mass stability analysis that includes the proposed C&D waste and the existing municipal solid waste
2. Perform a waste mass stability of interim slopes
3. Evaluate stability and settlement of the final and alternate covers
4. Evaluate settlement of the foundation soils
5. Perform a preliminary review of our stability analyses with respect to seismic stability

2.0 Supplemental Waste Mass Stability Analyses

2.1 Discussion

We evaluated the deep-seated stability by performing two-dimensional, effective stress slope stability analyses for the final, closed geometry, using the computer program *GSLOPE Version 5.10*. This program performs a limit equilibrium analysis for potential mass failure along assumed failure surfaces. We assumed that the failure surfaces extend through the new waste, and into the underlying C&D waste and existing MSW waste. For our analyses, we used the geometry from the cross-sections presented on the following SAIC drawings:

550 Cleveland Avenue North | St. Paul, MN 55114
Phone 651-659-9001 | Toll Free 800-972-6364 | Fax 651-659-1379 | www.amengtest.com | AA/EEO
This document shall not be reproduced, except in full, without written approval from American Engineering Testing, Inc.

- Drawing Number P3-20.0, "Typical Landfill Section B" dated 11/22/2011
- Drawing Number P3-23.0, "Typical Landfill Section E" dated 11/22/2011

Copies of these sections are attached in Appendix A. We understand that the final cover for the existing MSW landfill, below the new C&D waste, will consist of 3 feet of soil with no geosynthetics. We assume that this soil will be sand. We also assumed that there is a textured HDPE liner beneath the existing MSW landfill.

Due to the high variability of municipal waste, conventional *in situ* testing or laboratory testing to evaluate the engineering properties of the waste is not practical. There is no data available concerning the engineering properties of the new MSW waste, the C&D waste, the asbestos fill, and the existing MSW waste. Therefore, for our analyses we used published and assumed estimated effective stress values of shear strength, cohesion, and unit weight for municipal solid waste (Eid, et al, 2000, Singh and Murphy 1990), and we also used these same values for the C&D waste, asbestos fill, and the existing MSW waste. Please contact us if specific shear strength and unit weight data become available, and we can then re-evaluate our analyses. In addition, because specific laboratory test results are not available, we have assumed engineering properties for the drainage sand ("Protective Soil Layer") and the interface friction angle between the sand the geomembrane. The engineering properties used in our analyses are presented in Table 2-1.

TABLE 2-1 ASSUMED ENGINEERING PROPERTIES FOR ANALYSES

Material	Effective Friction Angle, peak ϕ'(degrees)	Effective Friction Angle, L.D.[1] ϕ'(degrees)	Unit Weight, γ (pcf)	Effective Cohesion (peak), c' (psf)	Effective Cohesion (L.D.[1]), c' (psf)
New and Existing MSW, New C&D Waste, Asbestos Fill	35°	28°	65	525	0
Drainage Sand	29°	29°	110	0	0
Interface between Sand/textured HDPE or LLDPE	30°	25°	N/A	0	0

1: Large Displacement

2.2 Waste Mass Stability

We analyzed potential circular failure surfaces and potential block (sliding) failure surfaces at Sections B and E. We assume that excess pore pressure will not develop within the waste either through hydrostatic pressure or gas pressure. The development of excess pore pressure would substantially reduce the factor of safety for stability. The results of our stability analyses using

peak strength values are presented in Appendix B. In summary, the minimum factor of safety is greater than 1.5, and in our judgment, is acceptable.

Due to the potential for variability of the engineering properties of the waste, we also performed a limited sensitivity analysis by evaluating the effect on the factor of safety by varying the strength parameters. The shear strength parameters used are presented in Table C-3 of our original report. The results of this limited sensitivity analysis are presented in attached Appendix B. The results indicate a factor of safety ranging from 1.47 to 2.78. In our judgment, these are acceptable.

To address the potential for progressive failure, we also performed an additional stability analysis using the assumed large displacement interface shear strengths presented in Table 2-1. The results of this analysis are presented in attached Appendix B. The calculated factor of safeties are in excess of 1.5, and in our judgment, are acceptable.

2.3 Interim Slopes

We understand that interim slopes will be constructed no steeper than 3H:1V. We evaluated the interim slope waste mass stability assuming a cross section from Section E for the apparent tallest interim slope height of about 270 feet, with the waste placed on the maximum 1% sloping foundation grade. We assume that the interim waste will not be placed on slopes steeper than 1%, nor will they be constructed with a slope face steeper than 3H:1V. The results are presented in Appendix C. For the assumed peak strength parameters, the calculated factor of safety was 2.64 for a theoretical circular failure surface, and 2.42 for a theoretical block failure surface. The factor of safety assuming large displacement strength parameters was 1.60 and 1.76, respectively. In our judgment, these factor of safeties are acceptable.

3.0 Stability Analysis of Final and Alternate Cover Systems

We performed an "infinite" slope stability analysis to evaluate the stability of the final and alternate cover system following procedures described by Qian, et al (2002). The final cover profile consists of a 6-inch thick topsoil or 4-inch thick rock layer, a 12-inch thick erosion layer, a 40 mil textured LLDPE liner, an 18-inch thick infiltration layer, a 6-inch thick intermediate cover layer, and a 6-inch thick daily cover layer overlying the refuse. We understand that the maximum calculated head on top of the LLDPE liner within the erosion layer along the 3H:1V side slopes is 5.825 inches (0.49 feet). We assume that the erosion layer will consist of sand having less than 10% passing the No. 200 sieve.

For our analyses, we assumed a maximum slope grade of 3H:1V. We also assumed that the LLDPE liner is appropriately anchored such that there will be no slippage between this and the underlying materials. The scope of our analyses does not include an evaluation of the anchored trench design nor the adequacy of the strength of the geomembrane to prevent material rupture or creep failure. We understand that the landfill will incorporate an adequate landfill gas collection system; therefore, landfill gas pressures have not been included in the calculations. Landfill gas

pressure can substantially reduce the factor of safety. We assumed a peak interface friction angle of 28° between the LLDPE and the sand ("erosion layer") cover. We also assumed a friction angle of 29° for the sand cover soils.

The results are presented in Appendix E. The results indicate that for a no water flow condition, the calculated factor of safety is 1.61. Assuming a saturated depth of 0.49 feet within the cover soil above the LLDPE, with seepage parallel to the liner, the calculated factor of safety is 1.33 for the assumed interface friction angle between the LLDPE and the cover soil of 28°. To achieve a factor of safety of 1.5 for this seepage condition, both the interface friction angle and the internal friction angle of the sand cover soils needs to be at least 31°.

The alternate cover will consist of a 4-inch thickness of "rock armor," 18 inches of sand compacted to 90% Standard Proctor maximum dry density, and 6 inches of sand compacted to 80% Standard Proctor maximum dry density, overlying the refuse. Laboratory test results provided to us indicate that this sand has 13.7% passing the No. 200 sieve. The sand compacted to 90% has a friction angle of 25° as tested by the direct shear test. The results of our calculations are presented in Appendix E. Assuming a friction angle of 25° for both the "90% density" sand and the "80% density" sand, the results indicate that for a no water flow condition, the calculated factor of safety is 1.41. Seepage flow within the sand will lower the factor of safety. We have included a graph showing factor of safety versus saturation depth for parallel seepage, which indicates that the factor of safety drops below 1.0 for a saturation depth of about 1.25 feet.

4.0 Settlement Evaluation

4.1 Final Cover Settlement and Strain

Our settlement evaluation for the final cover followed procedures and assumptions stated in our original report. As part of our settlement calculations we also evaluated the strain in the liner cover system, and also the anticipated change in surface grade between evaluation points. We evaluated the settlement at two cross sections; Sections B and E, as referenced in Section 2.0 of this report. The results are attached in Appendix D. In summary, the maximum tensile strain calculated is less than 0.01%, with most values less than zero (compression). Published information indicates that LLDPE can generally be assumed to have a yield strain on the order of 12%, or more; therefore, in our judgment, the calculated tensile strain should not adversely affect the LLDPE liner.

4.2 Piggyback Liner Settlement and Strain

Our settlement evaluation for the piggyback liner followed procedures and assumptions stated in our original report. As part of our settlement calculations we also evaluated the strain in the piggyback liner cover system, and also the anticipated change in grade between evaluation points. We evaluated the settlement at two cross sections; Sections B and E, as referenced in Section 2.0 of this report. The results are attached in Appendix D. In summary, the maximum tensile strain calculated is 0.206%. Published information indicates that HDPE can generally be assumed to have a yield strain on the order of 12%, or more, and GCL can generally be assumed

to have a yield strain of 1% to 10%. The geogrid will have an allowable strain of 5%. Based on our results, in our judgment, the calculated tensile strain should not adversely affect these geosynthetic materials.

4.3 Foundation Settlement, Heave, and Strain

Previous borings performed in the area were used to evaluate the subsurface conditions needed for estimation of foundation settlement and excavation-induced heave evaluation (see *SAIC Appendix 3K – Attachment 3, Borings*). The foundation is defined in this report as the base of the existing MSW landfill. No new borings or laboratory testing were performed for this evaluation.

The settlement analyses were made using the computer program *FoSSA 2.0*, which utilizes conventional Boussinesq stress theory. The program assesses stresses and settlements under embankments. The landfill was modeled as a two-dimensional embankment. We used elastic theory for the foundation soils and conventional consolidation theory for the different waste materials (i.e. the existing MSW, the C&D fill, and the asbestos fill).

The estimated heave of the foundation soils due excavation is plotted as estimated elastic rebound and are presented on the attached graphs in Appendix E. The amount of excavation-induced heave calculated is, in our opinion, small, generally less than about 0.25 feet.

The estimated foundation settlement due to the full MSW height are presented on the attached graphs in Appendix E. The foundation settlement is estimated to be less than one foot, and the strain is estimated to be 0.03%, or less. Published information indicates that HDPE can generally be assumed to have a yield strain on the order of 12%, or more. In our judgment, the estimated amount of settlement and strain should not adversely affect the existing HDPE liner.

5.0 Preliminary Seismic Stability Analyses

You indicated that originally the landfill was located outside any designated seismic impact zones at the time of the original construction; however, based on current USGS seismic maps the facility is now within a seismic impact zone that exceeds the 30 TAC §330.557 standard. A seismic impact zone is defined as an area with a 10% or greater probability that the maximum horizontal acceleration in rock will exceed 0.10g in 250 years. You explained; however, that this standard only applies to new MSW facilities and not vertical expansions as proposed. Although not specifically required, we have, however, performed a preliminary review of our stability analyses with respect to seismic stability.

According to the USGS Ground Motion Parameter Calculator, the site specific maximum seismic horizontal acceleration with a 2% probability of exceedance in 50 years (equivalent to 10% probability in 250 years) is 0.116g for a one second period. We performed a pseudo-static screening analysis following procedures described by Bray, et al (1998), and Duncan and Wright (2005). Our analysis assumed an acceleration multiplier of 0.75. The results are attached. In summary, the screening analysis for the interim slope, and waste mass stability through Section

E, resulted in a factor of safety of in excess of 1.2. The screening analysis for the final cover, assuming a large displacement interface friction angle of 25° between the LLDPE and the cover soils, and a dry condition, resulted in a factor of safety of 1.08. The calculated factor of safety for these screening analyses are greater than 1.0, and as such, permanent seismic displacements are estimated to be less than one foot.

6.0 Concluding Comments

No new laboratory testing has been authorized as part of this supplemental work. It is important; however, that our assumed engineering properties are confirmed by specific testing prior to construction. Apart from the typical testing required, such as Proctor tests and gradation analyses, additional testing to address the assumed parameters in this report should include, but not be limited to, the following items:

1. Final Cover System
    a. Direct shear test on the Final Cover "Erosion Layer" soil.
    b. Large-scale direct shear test to determine the interface friction angle between the "Erosion Layer" soil and the 40 mil LLDPE.
2. Alternate Cover System
    a. Direct shear test on the sand compacted to 80% of the maximum Standard Proctor dry density.
3. Piggyback Liner System
    a. Large-scale direct shear test to determine the interface friction angle between the "Protective Soil Layer" and the 60 mil HDPE.
4. Basal Permitted and Alternate Liner Systems
    a. Direct shear test on the "Protective Soil Layer."
    b. Large-scale direct shear test to determine the interface friction angle between the "Protective Soil Layer" and the 60 mil HDPE.

The geosynthetic manufacturers should also provide the allowable yield strain for all of their proposed materials.

7.0 Limitations

Within the limitations of scope, budget, and schedule, we have endeavored to provide our services according to generally accepted geotechnical engineering practices at this time and location. Other than this, no warranty, either express or implied, is intended.

PREDICTED SETTLEMENT AND STRAIN OF PIGGYBACK LINER DUE TO COMPRESSION OF THE EXISTING MSW AND NEW C&D WASTE

McCombs Landfill
American Engineering Testing, Inc.
AET No. 01-05106

Settlement of Existing Landfill

Ref. Qian, X., et. al., "Geotechnical Aspects of Landfill Design and Construction," Prentice Hall, 2002, pg. 548

Project: McCombs Landfill **AET No.** 01-05106
Section: Section B **Date:** July 2012

Compression of Existing MSW and New C-D

Primary Settlement

$\Delta Z_c = C_c' \times H_o \times \log (\sigma_o + \Delta\sigma / \sigma_o)$

ΔZ_c = primary settlement of existing landfill
H_o = initial thickness of the waste layer of the existing landfill
C_c' = modified primary compression index. Cc'= 0.17~0.36
σ_o = existing overburden pressure acting at the mid level of the waste layer
$\Delta\sigma$ = increment of overburden pressure due to vertical expansion

Secondary Settlement

$\Delta Z_\alpha = C_\alpha' \times H_o \times \log (t2 / t1)$

ΔZ_α = secondary settlement of existing landfill
H_o = initial thickness of the waste layer before starting secondary settlement
C_α' = modified secondary compression index. C_α' = 0.03~0.1
t1 = starting time of the secondary settlement. It is assumed to be equal to the age of existing landfill
t2 = ending time of the secondary settlement

Enter Assumed Parameters

Cc' =	0.17	t1 =	9
Ca' =	0.03	t2 =	59
Unit Weight of existing waste (pcf) =	65		
Unit Weight of new waste (pcf) =	65

Settlement of Existing Landfill

Ref. Qian, X., et. al., "Geotechnical Aspects of Landfill Design and Construction," Prentice Hall, 2002, pg. 548

Project: McCombs Landfill **AET No.** 01-05106
Section: Section B **Date:** July 2012

Final Cover Settlement

Primary Settlement

$\Delta Z_c = C_c' \times H_o \times \log (\sigma_o + \Delta\sigma / \sigma_o)$

ΔZ_c = primary settlement of existing landfill
H_o = initial thickness of the waste layer of the existing landfill
C_c' = modified primary compression index. Cc'= 0.17~0.36
σ_o = existing overburden pressure acting at the mid level of the waste layer
$\Delta\sigma$ = increment of overburden pressure due to vertical expansion

Secondary Settlement

$\Delta Z_\alpha = C_\alpha' \times H_o \times \log (t2 / t1)$

ΔZ_α = secondary settlement of existing landfill
H_o = initial thickness of the waste layer before starting secondary settlement
C_α' = modified secondary compression index. C_α' = 0.03~0.1
t1 = starting time of the secondary settlement. It is assumed to be equal to the age of existing landfill
t2 = ending time of the secondary settlement

Enter Assumed Parameters

Cc' =	0.36	t1 =	9
Ca' =	0.1	t2 =	59
Unit Weight of existing waste (pcf) =	65		
Unit Weight of new cover soils (pcf) =	125

Anchor Trench Calculations

SAIC®

Memorandum

To: TCEQ

From: Fred J. Doran, P.E., SAIC

Subject: Anchor Trench Design for Pullout and Interface Liner System Stability Calculations

Date: November 2, 2012

Attached is the anchor trench design for pullout and interface liner system stability calculations completed by SAIC on July 17, 2012. The calculations were completed using the references identified here within. Results indicate the following factors of safety:

- Anchor trench pullout versus tear: 1.10

The anchor trench was designed with both constructability and strength in mind. The anchor trench should fail and pullout rather than the sideslope geomembrane liner failing and tearing, since it will be easier to observe and repair an anchor trench failure. However, the anchor trench also has to aid in construction, and providing a shallower anchor trench may have issues with wind and water migration under the liner edge. The calculated factor of safety of 1.1 is considered adequate as it shows that anchor trench pullout will be the governing failure mode. Also note that the configuration is temporary as the slope will be filled against after phase construction.

- Interface liner system stability (gravity): 1.37

The interface liner system stability calculations are also most critical during and immediately after phase construction (until waste filling begins within the phase) and are a temporary condition. As waste is filled against the slope, the waste creates a buttress to provide more strength against failure. The calculated 1.37 factor of safety is considered adequate for temporary conditions.

- Interface liner system stability (equipment): 1.31 and 1.36

As described above, the calculated factors of safety are for temporary conditions during phase construction and are considered adequate.

Problem Statement:

PROBLEM: The anchor trench is designed to prevent wind and water migration under the geosynthetics, but is not designed to allow the geosynthetics to be in tension. In failure this design allows the geosynthetics to pull out of the anchor trench rather than tear.

OBJECTIVE: Determine if the designed anchor trench is adequate.

Equation:

Anchor Trench Capacity = $F_U + F_L + F_{AT1} + F_{AT2} + F_{BU} + F_{BL}$

Where:

F_U =	**0**	**lb/ft**	Frictional force above geomembrane (assumed to be negligible since cover soil likely moves with geomembrane)
$F_L = d_{cs} * \gamma_{cs} * L_{ro} * \tan\phi_2$			
d_{cs} =	2	ft	Depth of protective cover on the liner runout, design value
γ_{cs} =	110	pcf	Unit weight of protective cover of anchor trench, assumed value
L_{RO} =	4	ft	Runout length with soil cover, design value
ϕ_2 =	24	°	Most critical friction angle below geomembrane (woven geotextile to soil, assumed value)
	0.42	radians	
F_L =	**391.58**	**lb/ft**	Calculated
$F_{AT1} = K_A([0.5d_{AT} * \gamma_{cc} + d_{cs} * \gamma_{cs}]d_{AT})*\tan\phi_1$			
$K_a = \tan(45° - \phi_0/2)^2$			Active coefficient of earth pressure
ϕ_0 =	30	°	Internal friction angle of backfill soil, assumed value
	0.52	radians	
K_a =	0.33		Calculated
d_{AT} =	2	ft	Depth of ancor trench, design value
γ_{cc} =	110	pcf	Unit weight of anchor trench backfill, assumed value
d_{cs} =	2	ft	Depth of protective cover on the liner runout, design value
γ_{cs} =	110	pcf	Unit weight of protective cover of anchor trench, assumed value
ϕ_1 =	25	°	Most critical friction angle above geomembrane (sand to textured geomembrane, assumed value)
	0.44	radians	
F_{AT1} =	**102.4**	**lb/ft**	Calculated
$F_{AT2} = K_p([0.5d_{AT} * \gamma_{cc} + d_{cs} * \gamma_{cs}]d_{AT})*\tan\phi_2$			
$K_p = \tan(45° + \phi_0/2)^2$			Passive coefficient of earth pressure
ϕ_0 =	30	°	Internal friction angle of backfill soil, assumed value
	0.52	radians	
K_p =	2.99		Calculated
d_{AT} =	2	ft	Depth of ancor trench, design value
γ_{cc} =	110	pcf	Unit weight of anchor trench backfill, assumed value
d_{cs} =	2	ft	Depth of protective cover on the liner runout, design value
γ_{cs} =	110	pcf	Unit weight of protective cover of anchor trench, assumed value
ϕ_2 =	24	°	Most critical friction angle below geomembrane (woven geotextile to soil, assumed value)
	0.42	radians	
F_{AT2} =	**878.9**	**lb/ft**	Calculated

$F_{BU} = \gamma_{cs}(d_{AT} + d_{cs})d_{BT} * \tan\phi_1$

γ_{cs} =	110	pcf	Unit weight of protective cover of anchor trench, assumed value
d_{AT} =	2	ft	Depth of ancor trench, design value
d_{cs} =	2	ft	Depth of protective cover on the liner runout, design value
d_{BT} =	0	ft	Runout length at base of anchor trench, design value
ϕ_1 =	25	°	Most critical friction angle above geomembrane (sand to textured geomembrane, assumed value)
	0.44	radians	
F_{BU} =	**0**	**lb/ft**	Calculated

$F_{BL} = \gamma_{cs}(d_{AT} + d_{cs})d_{BT} * \tan\phi_2$

γ_{cs} =	110	pcf	Unit weight of protective cover of anchor trench, assumed value
d_{AT} =	2	ft	Depth of ancor trench, design value
d_{cs} =	2	ft	Depth of protective cover on the liner runout, design value
d_{BT} =	0	ft	Runout length at base of anchor trench, design value
ϕ_2 =	24	°	Most critical friction angle below geomembrane (woven geotextile to soil, assumed value)
	0.42	radians	
F_{BL} =	**0**	**lb/ft**	Calculated

Anchor Trench Capacity = $F_U + F_L + F_{AT1} + F_{AT2} + F_{BU} + F_{BL}$

Anchor Trench Capacity = 1,373 lb/ft

The yield strength for textured 60 mil HDPE geomembrane is: **1,512 lb/ft**

Factor of Safety = HDPE Strength/Anchor Trench Capacity **FS = 1.10**

Interface Liner System Stability
McCombs Landfill MSW Permit 729B
Koerner and Soong Analysis of Liner System

Completed By:	TLK	7/17/2012
Checked By:	FJD	7/17/2012

Problem Statement:

In order to determine the required tensile strength of the geosynthetics to be placed as the liner beneath the protective soil, it is necessary to calculate the tensile forces placed on the liner system. After determining the tensile forces present in the cover liner system, it would be possible to define the requirements for an anchor trench. Tensile forces have been calculated by Koerner methodologies.

n	Variable	Value	Units	Source
Slope Length	L		75.2 Meters	Design (ft)
Protective Soil Density (Saturated)	$Dens_{ps(sat)}$		1762 kg/m^3	Assumed (pcf)

Interface Liner System Stability - D6N LGP Dozer on Slope
McCombs Landfill MSW Permit 729B
Koerner and Soong Analysis of Liner System

Completed By:	TLK	7/17/2012
Checked By:	FJD	7/17/2012

Problem Statement:

Further analysis was performed using Koerner and Soong's methodologies for analysis and design of veneer soils. This analysis included examination of the impact on that factor of safety by construction equipment.

NOTES

1. CONTOURS SHOWN REPRESENT TOP OF COMPACTED NATIVE SUBGRADE SOIL IN FUTURE CELLS OR INTERIM COVER SOIL IN EXISTING CELLS.
2. BASE CONTOUR INTERVAL FOR SOLID CONTOURS IS FIVE FEET. BASE CONTOUR INTERVAL FOR DASHED CONTOURS IS ONE FOOT. ELEVATIONS ARE CITY OF EL PASO VERTICAL DATUM.
3. INTERIOR SECTOR BOUNDARY LOCATIONS FOR SECTORS B, D, E, AND F ARE CONSIDERED TO BE A MOVING TARGET AND MAY VARY DEPENDING ON THE AMOUNT OF FILL ON THE EXISTING UNLINED LANDFILL AT THE TIME OF CELL DEVELOPMENT. CURRENT INTERIOR SECTOR BOUNDARIES ARE BASED ON EXISTING CONDITIONS AS OF FEBRUARY 2011.
4. SEE DRAWING P3-28B FOR PIGGYBACK LINER LOCATIONS.

PROJECT NUMBER: 9631500115
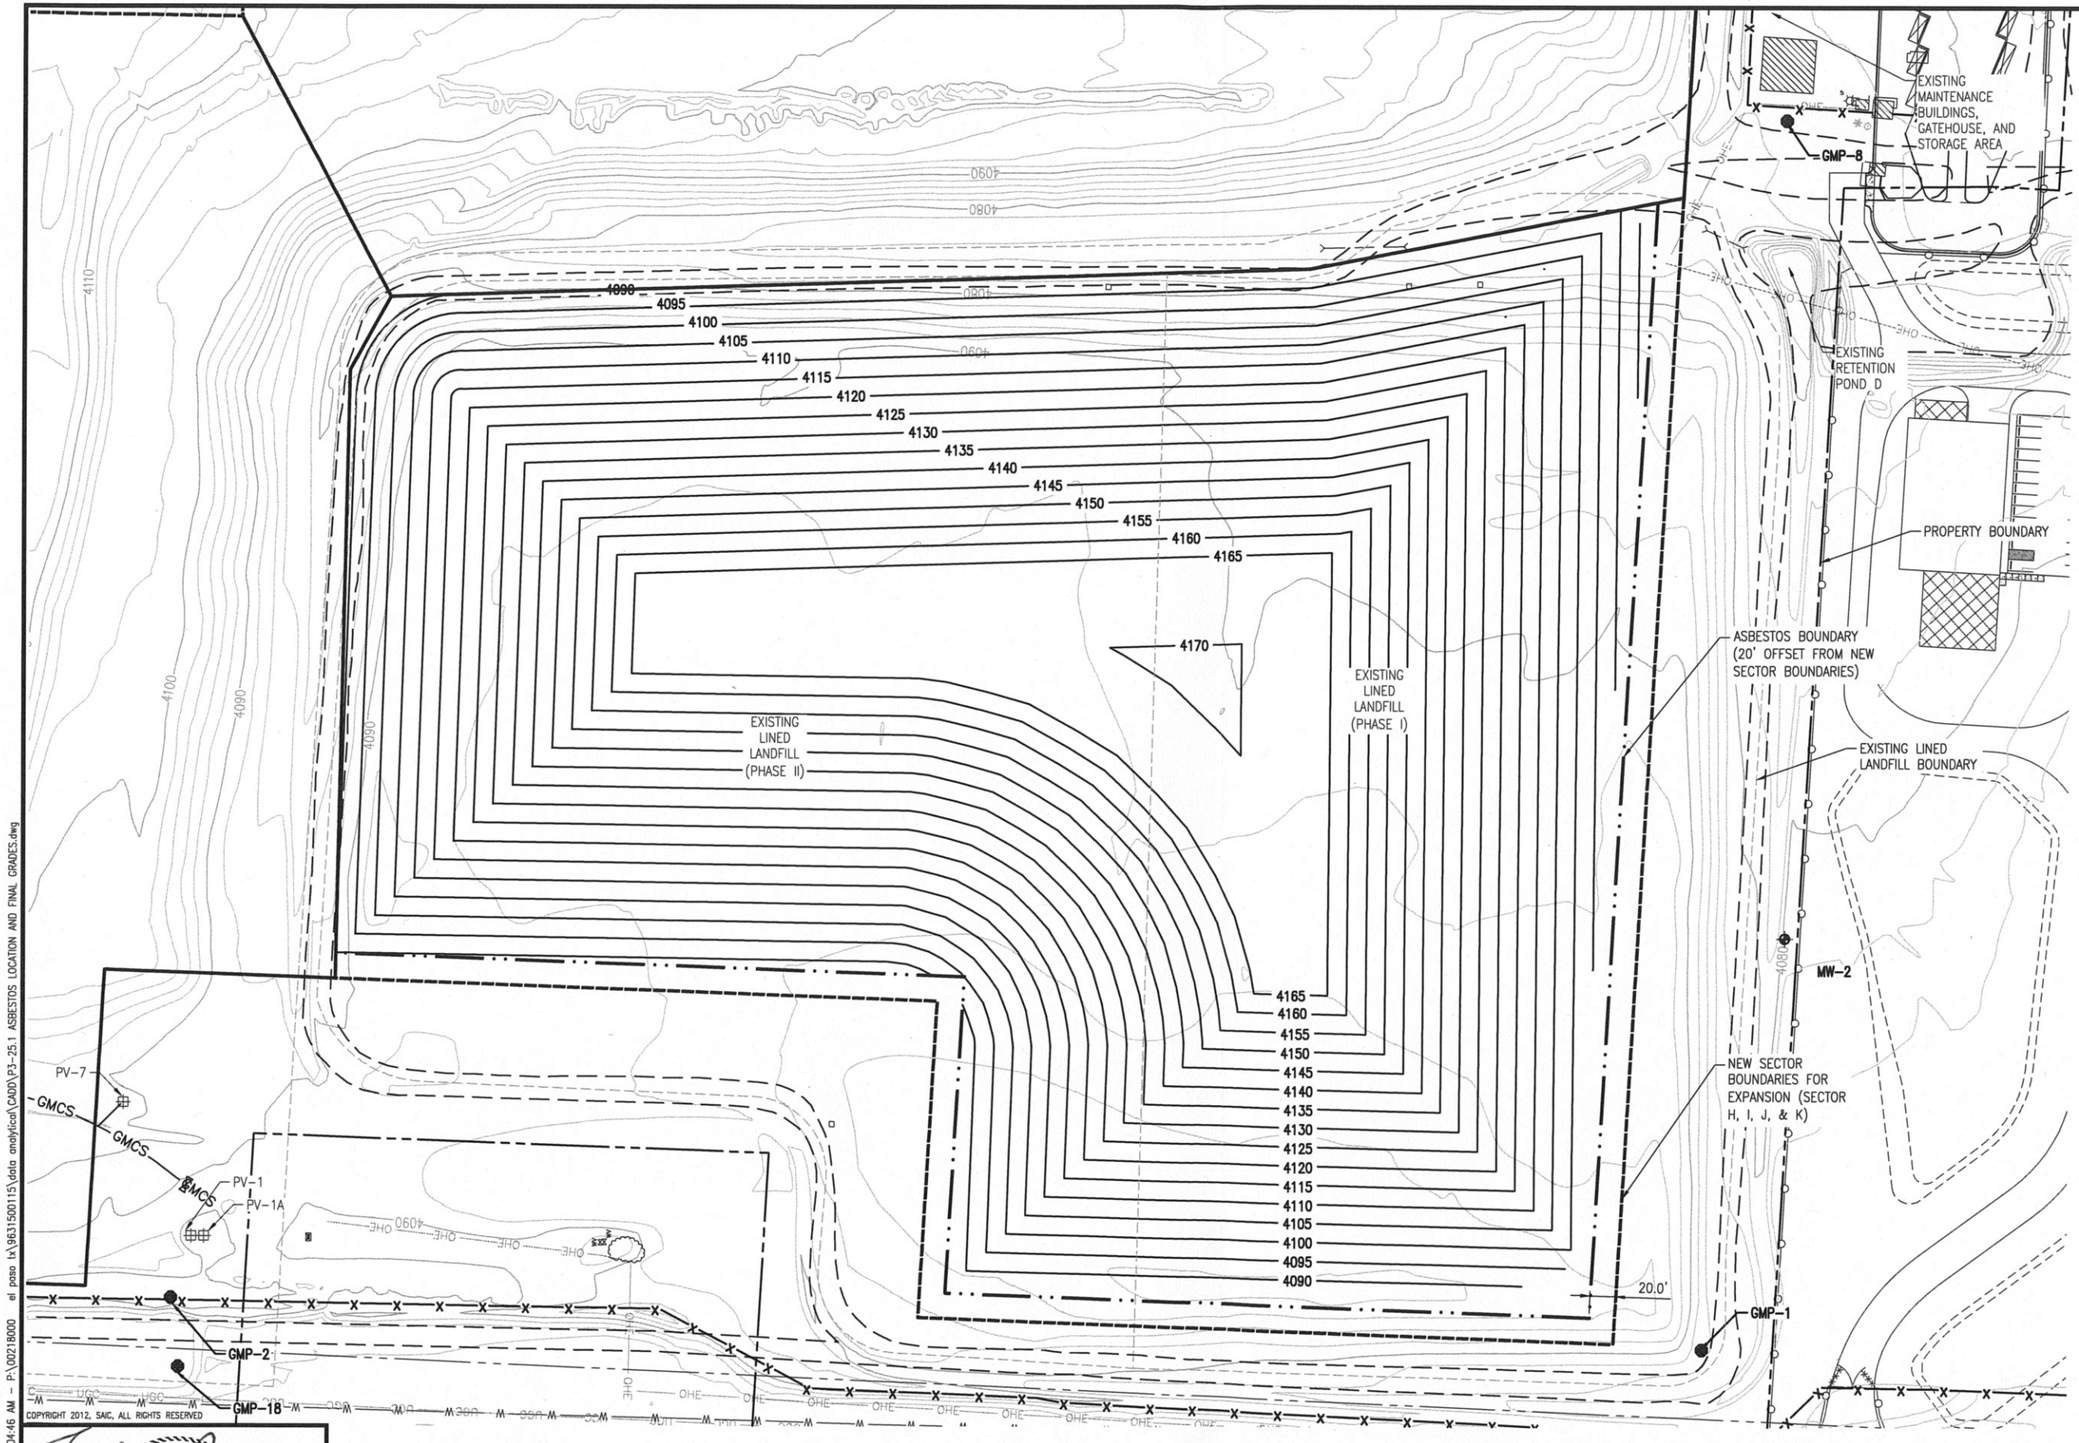
SHT. 58 OF: 78
DRAWING NUMBER: P3–25

Koller, Tonya L. 11/1/2012 11:36:57 AM – P:\60218000 el paso tx\9631500115\data analysis\CAD\P3–25 ASBESTOS LOCATION AND FINAL GRADES.dwg



NOTES

1. DIGITIZED TOPOGRAPHY FROM AERIAL SURVEY COMPLETED IN FEBRUARY 2011 BY COOPER AERIAL SURVEYS COMPANY, TUCSON, AZ. TOPOGRAPHY PROVIDED BY FRANK X. SPENSER & ASSOCIATES, INC., EL PASO, TEXAS.
2. COORDINATES ARE BASED ON THE TEXAS STATE PLANE COORDINATE SYSTEM, CENTRAL ZONE, NAD 83. ELEVATIONS ARE ~~NAVD 88~~ CITY OF EL PASO VERTICAL DATUM. NAVD 88 DATUM TO NGVD 29 DATUM, SUBTRACT 1.99–FEET. NGVD 29 DATUM TO CITY OF EL PASO DATUM, ADD 27.65–FEET.
3. EXISTING CONTOUR INTERVAL IS TWO FEET.
4. SITE TOPOGRAPHY MAY VARY DUE TO OWNER'S OPERATIONS.
5. DESIGN CONTOURS SHOWN REPRESENT TOP OF ASBESTOS FILL AREA. CONTOUR INTERVAL IS FIVE FEET.
6. TOP OF ASBESTOS CONTOURS ARE A MINIMUM OF 20–FEET FROM FINAL SIDESLOPE CONTOURS (SOUTH AND WEST SIDES) AND A MINIMUM OF 10–FEET FROM THE FINAL SURFACE OF THE AREA.

DETAIL 2 P3–20 2 P3–21 2 P3–22 2 P3–23 2 P3–26
FUTURE C&D LANDFILL
SCALE: 1/4"=1'-0"

NOTES

1. THE PIGGYBACK DESIGN ILLUSTRATES THE SEQUENCING FOR THE FILLING OF CONSTRUCTION AND DEMOLITION DEBRIS (C&D) AND SOILS OVER THE EXISTING UNLINED AND LINED AREAS OF THE LANDFILL. AFTER THE SURCHARGE OF C&D, SOIL WILL BE PLACED TO ACT AS THE SUBGRADE FOR THE VERTICAL EXPANSION.
2. ADDITIONAL SOIL MAY BE NECESSARY TO ACHIEVE BASE GRADES FOR THE MSW AREA. IN THE EVENT THAT MORE THAN 3–FEET OF SOIL IS ADDED ON TOP OF THE C&D FILL, ONLY THE TOP 3–FEET SHALL BE COMPACTED.

Appendix 3H
Site Life Projections

SAIC®

SAIC®

Appendix 3H
SITE LIFE PROJECTIONS

3H.1 Solid Waste Generation

The McCombs Landfill accepts waste generated in El Paso County, Texas. The Clint Landfill also accepts waste generated in El Paso County. The estimated rate of disposal was calculated assuming an annual population increase of 2% in growth, and assuming a disposal rate of 497,309 tons per year (in 2014 tonnage) until Clint Landfill closes in 2030. 3,000 tons per year are assumed from 2011 through 2013. After Clint Landfill closes, McCombs Landfill will receive all of the waste that would have previously gone to Clint Landfill, therefore the disposal rate at McCombs will raise from 45% of the county waste allocation to 100%. The 1990 base population for central, northeastern and northwestern areas of El Paso (areas where solid waste is planned to go to the McCombs Landfill) was used for the growth rate estimation. The population for the above mentioned areas in 1990 was 322,842 people.

The disposal rate for C&D waste was calculated assuming a disposal rate of 60,000 tons per year (this is the approximate tonnage of C&D disposed of at Clint Landfill 2284 in FY 2010), also with an annual increase of 2% growth.

3H.2 Air Apace utilization

An airspace utilization factor (AUF) of 0.60 tons per cubic yard (1200 pounds per cubic yard) of landfill airspace was utilized to calculate the site life projections for the volume available at the McCombs Landfill.

3H.3 Landfill Capacity

The total landfill capacity represents a total volume available for disposal of solid waste, daily cover material and intermediate cover material. AutoCAD Civil 3D 2011 computer software was utilized to estimate the total capacity. The total capacity is defined as the volume between the top of the geomembrane on the cell liner system and top of the final cover system. Sector A is currently being filled with waste so the existing capacity in that sector was evaluated between the existing contours in that sector and the top of the final cover system of that sector.

The total remaining landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including waste and daily, intermediate and final cover), which provides capacity through 2014 based on Table 3H-1. The total remaining landfill volume available for waste disposal, protective soil and daily, intermediate and final cover (including the remainder of Sector A) and all subsequent planned sectors (B through K) is 62,853,182 CY. The total remaining volume for waste disposal including intermediate cover using the prescriptive final cover profile is 60,675,743 CY. The total volume remaining for waste disposal including intermediate cover utilizing the alternative final cover profile is 60,973,535 CY. The sector

development plan can be seen in Appendix 3E - Site Layout Plans, Drawing P3-16 - Landfill Completion Plan.

3H.4 Site Life Calculations

Using the rate of 2% growth per year, an AUF of 1200 lb/cy for MSW and 1800 lb/cy for C&D, an increase in waste received after 2030, and the remaining capacity above, the remaining estimated life of the Landfill is until 2059 for both prescriptive and alternative final cover profiles. See Table 3H-1 and Table 3H-2 for MSW Prescriptive and Alternative Site Life Calculations and Table 3H-3 for C&D Site Life Calculations. See Table 3H-4 for Sector Volume Calculations.

Table 3H-1
Site Life Calculations for MSW (Prescriptive)

Growth Rate	2%	
In Place Tons	0	
AUF (tons/cy lb/cy)	0.6	1200
Beginning Tons per Year (in 2014 tons)		497,309
Remaining Sector A Capacity (Including Final Cover)		640,890
Waste Allocation:	45% McCombs	55% Clint

Total A-K	12,060,576	276.87	62,853,182	60,675,743	60,973,535
Total C&D	2,930,931.26	67.28	2,072,752	NA	NA

[A] – Net Volume less 60-inches (36-inches for prescriptive final cover and 24-inches for protective cover). Sector A volume only less 36-inches for prescriptive final cover.

[B] – Net Volume less 52-inches (24-inches for alternative final cover and 28-inches for protective cover). Sector A volume only less 28-inches for alternative final cover.

[C] – Volumes include intermediate cover.

SAIC®

Appendix 3H
SITE LIFE PROJECTIONS

3H.1 Solid Waste Generation

The McCombs Landfill accepts waste generated in El Paso County, Texas. The Clint Landfill also accepts waste generated in El Paso County. The estimated rate of disposal was calculated assuming an annual population increase of 2% in growth, and assuming a disposal rate of 497,309 tons per year (in 2014 tonnage) until Clint Landfill closes in 2030. 3,000 tons per year are assumed from 2011 through 2013. After Clint Landfill closes, McCombs Landfill will receive all of the waste that would have previously gone to Clint Landfill, therefore the disposal rate at McCombs will raise from 45% of the county waste allocation to 100%. The 1990 base population for central, northeastern and northwestern areas of El Paso (areas where solid waste is planned to go to the McCombs Landfill) was used for the growth rate estimation. The population for the above mentioned areas in 1990 was 322,842 people.

The disposal rate for C&D waste was calculated assuming a disposal rate of 60,000 tons per year (this is the approximate tonnage of C&D disposed of at Clint Landfill 2284 in FY 2010), also with an annual increase of 2% growth.

3H.2 Air Apace utilization

An airspace utilization factor (AUF) of 0.60 tons per cubic yard (1200 pounds per cubic yard) of landfill airspace was utilized to calculate the site life projections for the volume available at the McCombs Landfill.

3H.3 Landfill Capacity

The total landfill capacity represents a total volume available for disposal of solid waste, daily cover material and intermediate cover material. AutoCAD Civil 3D 2011 computer software was utilized to estimate the total capacity. The total capacity is defined as the volume between the top of the geomembrane on the cell liner system and top of the final cover system. Sector A is currently being filled with waste so the existing capacity in that sector was evaluated between the existing contours in that sector and the top of the final cover system of that sector.

The total remaining landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including ~~both~~ waste and daily, intermediate and final cover), which provides capacity through 2014 based on Table 3H-1. The total remaining landfill volume available for waste disposal, protective soil and daily, intermediate and final cover (including the remainder of Sector A) and all subsequent planned sectors (B through K) is ~~62,532,764~~***62,853,182*** CY. The total remaining volume for waste disposal including intermediate cover using the prescriptive final cover profile is ~~60,355,32~~***60,675,743*** CY. The total volume remaining for waste disposal including intermediate cover utilizing the alternative final cover profile is

~~60,653,116~~***60,973,535*** CY. The sector development plan can be seen in Appendix 3E - Site Layout Plans, Drawing P3-16 - Landfill Completion Plan.

3H.4 Site Life Calculations

Using the rate of 2% growth per year, an AUF of 1200 lb/cy for MSW and 1800 lb/cy for C&D, an increase in waste received after 2030, and the remaining capacity above, the remaining estimated life of the Landfill is until 2059 for both prescriptive and alternative final cover profiles. See Table 3H-1 and Table 3H-2 for MSW Prescriptive and Alternative Site Life Calculations and Table 3H-3 for C&D Site Life Calculations. See Table 3H-4 for Sector Volume Calculations.

[A] – Net Volume less 60-inches (36-inches for prescriptive final cover and 24-inches for protective cover). Sector A volume only less 36-inches for prescriptive final cover.

[B] – Net Volume less 52-inches (24-inches for alternative final cover and 28-inches for protective cover). Sector A volume only less 28-inches for alternative final cover.

[C] – *Volumes include intermediate cover.*

Appendix 3H
SITE LIFE PROJECTIONS

3H.1 Solid Waste Generation

The McCombs Landfill accepts waste generated in El Paso County, Texas. The Clint Landfill also accepts waste generated in El Paso County. The estimated rate of disposal was calculated assuming an annual population increase of 2% in growth, and assuming a disposal rate of 497,309 tons per year (in 2014 tonnage) until Clint Landfill closes in 2030. 3,000 tons per year are assumed from 2011 through 2013. After Clint Landfill closes, McCombs Landfill will receive all of the waste that would have previously gone to Clint Landfill, therefore the disposal rate at McCombs will raise from 45% of the county waste allocation to 100%. The 1990 base population for central, northeastern and northwestern areas of El Paso (areas where solid waste is planned to go to the McCombs Landfill) was used for the growth rate estimation. The population for the above mentioned areas in 1990 was 322,842 people.

The disposal rate for C&D waste was calculated assuming a disposal rate of 60,000 tons per year (this is the approximate tonnage of C&D disposed of at Clint Landfill 2284 in FY 2010), also with an annual increase of 2% growth.

3H.2 Air Apace utilization

An airspace utilization factor (AUF) of 0.60 tons per cubic yard (1200 pounds per cubic yard) of landfill airspace was utilized to calculate the site life projections for the volume available at the McCombs Landfill.

3H.3 Landfill Capacity

The total landfill capacity represents a total volume available for disposal of solid waste, daily cover material and intermediate cover material. AutoCAD Civil 3D 2011 computer software was utilized to estimate the total capacity. The total capacity is defined as the volume between the top of the ***geomembrane*** ~~protective soil layer~~ on the cell liner system and ***top*** ~~bottom~~ of the final cover system. Sector A is currently being filled with waste so the existing capacity in that sector was evaluated between the existing contours in that sector and the ***top*** ~~bottom~~ of the final cover system of that sector.

The total remaining landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including ~~both~~ waste and daily***, intermediate and final*** cover), which provides capacity through 2014 based on Table 3H-1. The total remaining landfill volume available for waste disposal***, protective soil and daily, intermediate and final cover (***including the remainder of Sector A***)*** and all subsequent planned sectors (B through K) is 62,532,764 CY. ***The total remaining volume for waste disposal using the prescriptive final cover profile is 60,355,324 CY. The total volume remaining for waste disposal utilizing the alternative final cover profile is***

60,653,116 CY. The sector development plan can be seen in Appendix 3E - Site Layout Plans, Drawing P3-16 - Landfill Completion Plan.

3H.4 Site Life Calculations

Using the rate of 2% growth per year, an AUF of 1200 lb/cy ***for MSW and 1800 lb/cy for C&D***, an increase in waste received after 2030, and the remaining capacity above, the remaining estimated life of the Landfill is ***until 2059 for both prescriptive and alternative final cover profiles*** ~~49 years~~. See Table 3H-1 and Table 3H-2 for MSW ***Prescriptive and Alternative*** ~~and C&D~~ Site Life Calculations ***and Table 3H-3 for C&D Site Life Calculations***. See Table 3H-~~3~~***4*** for Sector Volume Calculations.

3I.1 Introduction

This Leachate and Contaminated Water Plan has been developed in accordance with 30 TAC §330.65(c), §330.177, §330.207, §330.331(a)(2), and §330.333 for the McCombs Landfill (Landfill) located in El Paso, TX. This plan provides details of the collection, storage, and disposal of contaminated water, leachate, and gas condensate from the leachate collection system, gas monitoring and collection systems, and site operations.

3I.1.1 Definitions

Definitions for the following have been defined by TAC §330.3.

- (36) Contaminated Water – "Leachate, gas condensate, or water that has come into contact with waste."
- (57) Gas Condensate – "The liquid generated as a result of any gas recovery process at a municipal solid waste facility."
- (78) Leachate – "A liquid that has passed through or emerged from solid waste and contains soluble, suspended, or miscible materials removed from such waste."

3I.2 Leachate Management

The Leachate Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) was used to assist in the development of the following section and is provided in partial form as Appendix 3I, Attachment 3. Sections, Figures and Appendices not provided have been updated within.

3I.2.1 Leachate Generation

Leachate generation was estimated by running the Hydrologic Evaluation of Landfill Performance (HELP) Model, Version 3.07. The HELP model is a program that computes the water balance for municipal landfills based on weather, soil, and design data and uses solution techniques that account for the effects of surface storage, runoff, infiltration, evapotranspiration, vegetation, soil moisture storage, subsurface drainage, recirculation, and leakage.

The climate data for the simulations was synthetically generated using coefficients for El Paso, Texas. The various conditions modeled were as follows:

Table 3I-1
HELP Modeling Methodology/Assumptions

Scenario	Open Condition (Daily Cover)	Intermediate Cover Condition	Final Cover Condition (Crown)	Final Cover Condition (Side-Slopes)	Final Cover Condition (Crown) – Alt. Cap	Final Cover Condition (Side-Slopes) – Alt. Cap

1. Barrier soil (clay) utilized in original prescriptive liner and replaced by caliche in the 2002 Major Permit Amendment. A HELP model demonstration of the effectiveness of the GCL as compared to the barrier soil has been included in this analysis. Modeling for both caliche and GCL alternative liners is provided in Appendix 3J.

Each scenario was evaluated over a simulation period ranging from 4 years to 30 years, as noted in Table 3I-1. Scenarios were modeled to determine the peak daily value for hydraulic head over the liner, liner/cover system efficiency, and leachate generation. Detailed HELP model outputs for each scenario are included in Attachment 1 in Appendix 3I and Peak Daily Hydraulic Head Over Liner values are listed in Table 3I-2.

Table 3I-2
Peak Daily Hydraulic Head Over Base Liner

Scenario[1]	Average Head (inches)	Maximum Head (inches)
Open Condition –Scenario 1 Liner System[1]	2.216	3.677
Open Condition –Scenario 2 Liner System[1]	3.517	5.504
Intermediate Cover Condition	0.406	0.765
Final Cover Condition (Crown)	0.011	0.021
Final Cover Condition (Side Slopes)	0.003	0.008
Final Cover Condition (Crown) – Alternative Cap	0.032	0.032
Final Cover Condition (Side Slopes) – Alternative Cap	0.032	0.064

[1] – Scenario profiles are detailed in Section 3.4.
[2] – All scenarios shown with 100 percent recirculation of leachate collected from the liner.

3I.2.2 Leachate Collection

Leachate Collection System Design

The leachate collection system was designed in accordance with 30 TAC §330.331(a)(2) and §330.333. The leachate collection system and piping must be:

- Designed to maintain less than 30-centimeters (12-inches) of leachate depth over the liner;
- Made of materials that are chemically resistant. The leachate collection system materials shall be constructed of high density poly-ethylene (HDPE);
- Of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, cover materials, and any equipment; and
- Designed and operated to function through the scheduled closure and post-closure care period.

The system design shall consist of the following components:

- Estimated rate of leachate removal from the sump;
- Capacity of the sump;
- Pipe material and strength;
- Pipe network spacing and grading;
- Collection sump materials and strength;

- Drainage media specifications and performance; and,
- Demonstrate that pipes and perforations will be resistant to clogging and can be cleaned.

These design requirements are discussed in further detail in the sections below. Leachate collection system details are provided on Drawing P3-31 in Appendix 3G.

Leachate Collection Layer

30 TAC §330.333(3)(D) and (F)

The leachate collection layer consist of a 24-inch sand protective layer (drainage material) overlying the geomembrane liner. The drainage material will have a minimum coefficient of permeability of 1.0×10^{-3} cm/sec. The effectiveness of this drainage layer is demonstrated in the HELP model analyses completed in Attachment 1 in Appendix 3I. The leachate collection layer will slope at a minimum of one-percent to the leachate collection trench and pipe (maximum of 600-feet).

Existing Sector K sand was also constructed to have a minimum coefficient of permeability of 1.0×10^{-3}cm/sec.

Leachate Aggregate

As outlined in the drawings, the leachate aggregate shall consist of 12-inches of 1 ½-inch washed aggregate and 12-inches of pea-gravel. The aggregate gradation change is implemented to substitute using a geotextile to encase the aggregate, which can be a clogging potential long-term.

The 1 ½-inch washed aggregate backfill shall meet the following specifications:

- Clean, washed, non-carbonate, sub-angular to rounded material, bank run gravel with no organic matter. Crushed aggregate, concrete, bituminous, or limestone not allowed. Soil Classification of GW or GP;
- Meeting the following Gradation (ASTM D422):
  1. 100% passing 1 ½-inch sieve
  2. 0% passing ¾-inch sieve

The pea-gravel backfill shall meet the following specifications:

- Durable washed, non-carbonate, coarse-rounded to sub-angular gravel exhibiting the following relationship to the drainage sand layer:
  1. D15 (Pea-gravel)/D85 (Drainage Sand) < 4 to 5
  2. D15 (Pea-gravel)/D15 (Drainage Sand) < 20
     - Where D_{15} and D_{85} are the diameters which 15% and 85% by weight (respectively) are finer.

Leachate Collection Trenches and Piping

30 TAC §330.333(2) and §330.333(3)(C), (E) and (G)

The leachate collection trenches will slope at a minimum of one-percent to the leachate collection sumps. The leachate collection piping will be placed at the center of the leachate collection trench and will be required to meet the following specifications:

- HDPE pipe designated as PE 3408;
- SDR 9 for perforated leachate collection pipe in trenches (8-inch), cleanout riser pipes (8-inch), and for side-slope riser (SSR) pipes (18-inch);
- Maximum deflection of five percent;
- Pipe perforations for leachate collection piping: ½-inch in diameter, 90-degrees apart symmetrical around the pipe, 5-inch linear spacing (Drawing P3-31 in Appendix 3G); and
- Pipe perforations for sump collection piping: ½-inch in diameter, 45-degrees apart symmetrical around the pipe, 3-inch linear spacing (Drawing P3-32 in Appendix 3G).

Calculations for wall crushing, wall buckling, and ring deflection based on the above design parameters are provided in Attachment 2 in Appendix 3I. Calculations show that the leachate collection systems are of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, waste cover materials, and by any equipment used at the landfill.

Pipe strength calculations were performed separately for the existing lined Phase I/II area (Sector K) to check the pipe strength of the existing pipe in place (6" SDR 11 HDPE pipe). The Sector K pipe calculations are also provided in Appendix 3I, Attachment 2. Calculations show that the existing pipe meets or exceeds the wall crushing, wall buckling and ring deflection requirements for all but the Watkins-Gaube ring deflection. The Watkins-Gaube ring deflection was calculated at 5.15% deflection, which is slightly over the recommended maximum deflection (5%) but under the allowable deflection (7.5%). The pipe is considered to be of sufficient strength and thickness to prevent collapse under the pressures exerted by the additional overlying wastes and waste cover materials for Sector K. Equipment calculations were not provided for Sector K as the critical time for equipment operations over pipe is during the initial lifts of waste being placed in the cell and Sector K already has approximately 50-feet of waste in place to help prevent collapse from equipment.

All leachate piping will have an attached pipe that leads to a reachable point so that the pipe is able to be accessed for cleaning (detail provided on Drawing P3-31 in Appendix 3G).

Geotextile Cushion

Cushion geotextile will be placed between the geomembrane and the leachate collection backfill (and piping) for puncture protection. The geotextile cushion layer shall be a non-woven polypropylene or polyester fabric required to meet the following specifications:

- Fabric Weight: 16 oz per square yard minimum;
- Puncture Resistance: 240 lbs (ASTM D-4833);

Geotextiles will be required to have a sewn seam or an 18-inch minimum sheet overlap.

Leachate Sump and Pump

30 TAC §330.333(3)(A) and (B)

The leachate sump will consist of a 3-foot deep rectangular area. The sump will have a minimum nominal dimension of 8-foot by 8-foot at the base and 26-foot by 26-foot at the top; for a minimum volume of 948 cubic feet (CF). The capacity of the sump has been selected to limit the maximum head on the liner. The media within the sump is to meet the same specifications as that of the 1½-inch aggregate specified for leachate collection aggregate. The average porosity for this aggregate is assumed to be 30%. Based on the porosity, 284 CF (2,124 gallons) in the sump will be available for leachate storage.

Based on the HELP model, the average yearly leachate generation rate for the open condition (maximum leachate generation) is 418 CF/acre/year (or 0.2 gallons per minute (gpm) based on the largest designed sector of 39-acres). Therefore, the recommended pumping size is from 5 gpm to 10 gpm to allow for periodic increases in precipitation.

The pumps will be operated by level transducers to ensure that leachate head does not exceed 12-inches over the liner (or approximately 48-inches in the sump, dependent on actual construction). Transducers will cycle on at approximately 36-inches of head within the sump (or 0-inches of head on the liner) and cycle off at approximately 6-inches of head within the sump. The pump hour reading will be recorded on a quarterly basis and kept in the Site Operating Record.

The leachate sump for Sector K was designed to have a nominal dimension of 7-foot by 7-foot at the base and 21-foot by 21-foot at the top; for a minimum volume of 735 cubic feet (CF). The average porosity for the aggregate is assumed to be 30%. Based on the porosity, 221 CF (1,653 gallons) in the sump are available for leachate storage. Based on the HELP model, the average yearly leachate generation rate for the open condition is 418 CF/acre/year (or 0.1 gpm based on Sector K size of 16.95 acres).

3I.2.3 Leachate Storage

Leachate will be stored within the leachate sump and within the waste mass on site.

3I.2.4 Leachate Disposal

Leachate will be disposed of within the waste mass on site.

3I.2.5 Leachate Recirculation

Leachate removed from the sumps will be recirculated within the waste mass. As shown in the HELP model results in Attachment 1 in Appendix 3I, 100% of the leachate can be recirculated back into the waste mass, while still maintaining less than 12-inches of leachate head on the liner.

The volume of leachate removed and recirculated, based on the sump pump hour meter reading, will be recorded quarterly in the Site Operating Record. Periodic analysis of leachate quality will also be placed in the Site Operating Record.

3I.3 Contaminated Water Management

The Contaminated Water Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) is included in partial form for compliance with 30 TAC §330.305 (b) and (c) Attachment 3 in Appendix 3I. No changes are recommended from this design.

Stormwater that comes into contact with the active working face and is not contained within the site run-on/runoff berms will be managed in the following manner:

- Contaminated water will be contained as best possible within site sedimentation basins or other low-lying areas onsite;
- Testing will be completed on the contaminated water in accordance with the site SWPPP; and
- If testing indicates that the water is contaminated, it will be pumped out of the containment area into a tanker truck and transferred to the El Paso Waste Water Treatment Plant.

Any water that infiltrates or evaporates prior to being transferred offsite shall be considered mitigated or controlled and no further action will be taken.

3I.4 Gas Condensate Management

If gas condensate is produced, it will be stored and disposed of as leachate.

SAIC®

3I.1 Introduction

This Leachate and Contaminated Water Plan has been developed in accordance with 30 TAC §330.65(c), §330.177, §330.207, §330.331(a)(2), and §330.333 for the McCombs Landfill (Landfill) located in El Paso, TX. This plan provides details of the collection, storage, and disposal of contaminated water, leachate, and gas condensate from the leachate collection system, gas monitoring and collection systems, and site operations.

3I.1.1 Definitions

Definitions for the following have been defined by TAC §330.3.

- (36) Contaminated Water – "Leachate, gas condensate, or water that has come into contact with waste."
- (57) Gas Condensate – "The liquid generated as a result of any gas recovery process at a municipal solid waste facility."
- (78) Leachate – "A liquid that has passed through or emerged from solid waste and contains soluble, suspended, or miscible materials removed from such waste."

3I.2 Leachate Management

The Leachate Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) was used to assist in the development of the following section and is provided in partial form as Appendix 3I, Attachment 3. Sections, Figures and Appendices not provided have been updated within.

3I.2.1 Leachate Generation

Leachate generation was estimated by running the Hydrologic Evaluation of Landfill Performance (HELP) Model, Version 3.07. The HELP model is a program that computes the water balance for municipal landfills based on weather, soil, and design data and uses solution techniques that account for the effects of surface storage, runoff, infiltration, evapotranspiration, vegetation, soil moisture storage, subsurface drainage, recirculation, and leakage.

The climate data for the simulations was synthetically generated using coefficients for El Paso, Texas. The various conditions modeled were as follows:

A HELP model demonstration of the effectiveness of the GCL as compared to the barrier soil has been included in this analysis. Modeling for both caliche and GCL alternative liners is provided in Appendix 3J.

Each scenario was evaluated over a simulation period ranging from 4 years to 30 years, as noted in Table 3I-1. Scenarios were modeled to determine the peak daily value for hydraulic head over the liner, liner/cover system efficiency, and leachate generation. Detailed HELP model outputs for each scenario are included in Attachment 1 in Appendix 3I and Peak Daily Hydraulic Head Over Liner values are listed in Table 3I-2.

[1] – Scenario profiles are detailed in Section 3.4.
[2] – All scenarios shown with 100 percent recirculation of leachate collected from the liner.

3I.2.2 Leachate Collection

Leachate Collection System Design

The leachate collection system was designed in accordance with 30 TAC §330.331(a)(2) and §330.333. The leachate collection system and piping must be:

- Designed to maintain less than 30-centimeters (12-inches) of leachate depth over the liner;
- Made of materials that are chemically resistant. The leachate collection system materials shall be constructed of high density poly-ethylene (HDPE);
- Of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, cover materials, and any equipment; and
- Designed and operated to function through the scheduled closure and post-closure care period.

The system design shall consist of the following components:

- Estimated rate of leachate removal from the sump;
- Capacity of the sump;
- Pipe material and strength;
- Pipe network spacing and grading;

- Collection sump materials and strength;
- Drainage media specifications and performance; and,
- Demonstrate that pipes and perforations will be resistant to clogging and can be cleaned.

These design requirements are discussed in further detail in the sections below. Leachate collection system details are provided on Drawing P3-31 in Appendix 3G.

Leachate Collection Layer

30 TAC §330.333(3)(D) and (F)

The leachate collection layer consist of a 24-inch sand protective layer (drainage material) overlying the geomembrane liner. The drainage material will have a minimum coefficient of permeability of 1.0×10^{-3} cm/sec. The effectiveness of this drainage layer is demonstrated in the HELP model analyses completed in Attachment 1 in Appendix 3I. The leachate collection layer will slope at a minimum of one-percent to the leachate collection trench and pipe (maximum of 600-feet).

Existing Sector K sand was also constructed to have a minimum coefficient of permeability of 1.0×10^{-3}cm/sec.

Leachate Aggregate

As outlined in the drawings, the leachate aggregate shall consist of 12-inches of 1 ½-inch washed aggregate and 12-inches of pea-gravel. The aggregate gradation change is implemented to substitute using a geotextile to encase the aggregate, which can be a clogging potential long-term.

The 1 ½-inch washed aggregate backfill shall meet the following specifications:

- Clean, washed, non-carbonate, sub-angular to rounded material, bank run gravel with no organic matter. Crushed aggregate, concrete, bituminous, or limestone not allowed. Soil Classification of GW or GP;
- Meeting the following Gradation (ASTM D422):
  1. 100% passing 1 ½-inch sieve
  2. 0% passing ¾-inch sieve

The pea-gravel backfill shall meet the following specifications:

- Durable washed, non-carbonate, coarse-rounded to sub-angular gravel exhibiting the following relationship to the drainage sand layer:
  1. D15 (Pea-gravel)/D85 (Drainage Sand) < 4 to 5
  2. D15 (Pea-gravel)/D15 (Drainage Sand) < 20
     - Where D_{15} and D_{85} are the diameters which 15% and 85% by weight (respectively) are finer.

Leachate Collection Trenches and Piping

30 TAC §330.333(2) and §330.333(3)(C), (E) and (G)

The leachate collection trenches will slope at a minimum of one-percent to the leachate collection sumps. The leachate collection piping will be placed at the center of the leachate collection trench and will be required to meet the following specifications:

- HDPE pipe designated as PE 3408;
- SDR 9 for perforated leachate collection pipe in trenches (8-inch), cleanout riser pipes (8-inch), and for side-slope riser (SSR) pipes (18-inch);
- Maximum deflection of five percent;
- Pipe perforations for leachate collection piping: ½-inch in diameter, 90-degrees apart symmetrical around the pipe, 5-inch linear spacing (Drawing P3-31 in Appendix 3G); and
- Pipe perforations for sump collection piping: ½-inch in diameter, 45-degrees apart symmetrical around the pipe, 3-inch linear spacing (Drawing P3-32 in Appendix 3G).

Calculations for wall crushing, wall buckling, and ring deflection based on the above design parameters are provided in Attachment 2 in Appendix 3I. Calculations show that the leachate collection systems are of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, waste cover materials, and by any equipment used at the landfill.

Pipe strength calculations were performed separately for the existing lined Phase I/II area (Sector K) to check the pipe strength of the existing pipe in place (6" SDR 11 HDPE pipe). The Sector K pipe calculations are also provided in Appendix 3I, Attachment 2. Calculations show that the existing pipe meets or exceeds the wall crushing, wall buckling and ring deflection requirements for all but the Watkins-Gaube ring deflection. The Watkins-Gaube ring deflection was calculated at 5.15% deflection, which is slightly over the recommended maximum deflection (5%) but under the allowable deflection (7.5%). The pipe is considered to be of sufficient strength and thickness to prevent collapse under the pressures exerted by the additional overlying wastes and waste cover materials for Sector K. Equipment calculations were not provided for Sector K as the critical time for equipment operations over pipe is during the initial lifts of waste being placed in the cell and Sector K already has approximately 50-feet of waste in place to help prevent collapse from equipment.

All leachate piping will have an attached pipe that leads to a reachable point so that the pipe is able to be accessed for cleaning (detail provided on Drawing P3-31 in Appendix 3G).

Geotextile Cushion

Cushion geotextile will be placed between the geomembrane and the leachate collection backfill (and piping) for puncture protection. The geotextile cushion layer shall be a non-woven polypropylene or polyester fabric required to meet the following specifications:

- Fabric Weight: 16 oz per square yard minimum;
- Puncture Resistance: 240 lbs (ASTM D-4833);

Geotextiles will be required to have a sewn seam or an 18-inch minimum sheet overlap.

Leachate Sump and Pump

30 TAC §330.333(3)(A) and (B)

The leachate sump will consist of a 3-foot deep rectangular area. The sump will have a minimum nominal dimension of 8-foot by 8-foot at the base and 26-foot by 26-foot at the top; for a minimum volume of 948 cubic feet (CF). The capacity of the sump has been selected to limit the maximum head on the liner. The media within the sump is to meet the same specifications as that of the 1½-inch aggregate specified for leachate collection aggregate. The average porosity for this aggregate is assumed to be 30%. Based on the porosity, 284 CF (2,124 gallons) in the sump will be available for leachate storage.

Based on the HELP model, the average yearly leachate generation rate for the open condition (maximum leachate generation) is 418 CF/acre/year (or 0.2 gallons per minute (gpm) based on the largest designed sector of 39-acres). Therefore, the recommended pumping size is from 5 gpm to 10 gpm to allow for periodic increases in precipitation.

The pumps will be operated by level transducers to ensure that leachate head does not exceed 12-inches over the liner (or approximately 48-inches in the sump, dependent on actual construction). Transducers will cycle on at approximately 36-inches of head within the sump (or 0-inches of head on the liner) and cycle off at approximately 6-inches of head within the sump. The pump hour reading will be recorded on a quarterly basis and kept in the Site Operating Record.

The leachate sump for Sector K was designed to have a nominal dimension of 7-foot by 7-foot at the base and 21-foot by 21-foot at the top; for a minimum volume of 735 cubic feet (CF). The average porosity for the aggregate is assumed to be 30%. Based on the porosity, 221 CF (1,653 gallons) in the sump are available for leachate storage. Based on the HELP model, the average yearly leachate generation rate for the open condition is 418 CF/acre/year (or 0.1 gpm based on Sector K size of 16.95 acres).

3I.2.3 Leachate Storage

Leachate will be stored within the leachate sump and within the waste mass on site.

3I.2.4 Leachate Disposal

Leachate will be disposed of within the waste mass on site.

3I.2.5 Leachate Recirculation

Leachate removed from the sumps will be recirculated within the waste mass. As shown in the HELP model results in Attachment 1 in Appendix 3I, 100% of the leachate can be recirculated back into the waste mass, while still maintaining less than 12-inches of leachate head on the liner.

The volume of leachate removed and recirculated, based on the sump pump hour meter reading, will be recorded quarterly in the Site Operating Record. Periodic analysis of leachate quality will also be placed in the Site Operating Record.

3I.3 Contaminated Water Management

The Contaminated Water Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) is included in partial form for compliance with 30 TAC §330.305 (b) and (c) Attachment 3 in Appendix 3I. No changes are recommended from this design.

Stormwater that comes into contact with the active working face and is not contained within the site run-on/runoff berms will be managed in the following manner:

- Contaminated water will be contained as best possible within site sedimentation basins or other low-lying areas onsite;
- Testing will be completed on the contaminated water in accordance with the site SWPPP; and
- If testing indicates that the water is contaminated, it will be pumped out of the containment area into a tanker truck and transferred to the El Paso Waste Water Treatment Plant.

Any water that infiltrates or evaporates prior to being transferred offsite shall be considered mitigated or controlled and no further action will be taken.

3I.4 Gas Condensate Management

If gas condensate is produced, it will be stored and disposed of as leachate.

3I.1 Introduction

This Leachate and Contaminated Water Plan has been developed in accordance with 30 TAC §330.65(c), §330.177, §330.207, §330.331(a)(2), and §330.333 for the McCombs Landfill (Landfill) located in El Paso, TX. This plan provides details of the collection, storage, and disposal of contaminated water, leachate, and gas condensate from the leachate collection system, gas monitoring and collection systems, and site operations.

3I.1.1 Definitions

Definitions for the following have been defined by TAC §330.3.

- (36) Contaminated Water – "Leachate, gas condensate, or water that has come into contact with waste."
- (57) Gas Condensate – "The liquid generated as a result of any gas recovery process at a municipal solid waste facility."
- (78) Leachate – "A liquid that has passed through or emerged from solid waste and contains soluble, suspended, or miscible materials removed from such waste"

3I.2 Leachate Management

The Leachate Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) was used to assist in the development of the following section and is provided in partial form as Appendix 3I, Attachment 3. Sections, Figures and Appendices not provided have been updated within.

3I.2.1 Leachate Generation

Leachate generation was estimated by running the Hydrologic Evaluation of Landfill Performance (HELP) Model, Version 3.07. The HELP model is a program that computes the water balance for municipal landfills based on weather, soil, and design data and uses solution techniques that account for the effects of surface storage, runoff, infiltration, evapotranspiration, vegetation, soil moisture storage, subsurface drainage, recirculation, and leakage.

The climate data for the simulations was synthetically generated using coefficients for El Paso, Texas. The various conditions modeled were as follows:

Table 3I-1
HELP Modeling Methodology/Assumptions

Scenario	Open Condition (Daily Cover)	Intermediate Cover Condition	Final Cover Condition (Crown)	Final Cover Condition (Side-Slopes)	Final Cover Condition (Crown) – Alt. Cap	Final Cover Condition (Side-Slopes) – Alt. Cap

1. Barrier soil (clay) utilized in original prescriptive liner and replaced by caliche in the 2002 Major Permit Amendment. A HELP model demonstration of the effectiveness of the GCL as compared to the barrier soil has been included in this analysis. *Modeling for both caliche and GCL alternative liners is provided in Appendix 3J.*

Each scenario was evaluated over a simulation period ranging from 4 years to 30 years, as noted in Table 3I-1. Scenarios were modeled to determine the peak daily value for hydraulic head over the liner, liner/cover system efficiency, and leachate generation. Detailed HELP model outputs for each scenario are included in Attachment 1 in Appendix 3I and Peak Daily Hydraulic Head Over Liner values are listed in Table 3I-2.

Table 3I-2
Peak Daily Hydraulic Head Over Base Liner

Scenario[1]	Average Head (inches)	Maximum Head (inches)
Open Condition – Prescriptive Liner with Barrier Soil	2.216	3.677
Open Condition – Alternative Liner with GCL	3.594	5.607
Intermediate Cover Condition	0.407	0.765
Final Cover Condition (Crown)	0.011	0.021
Final Cover Condition (Side Slopes)	0.003	0.007
Final Cover Condition (Crown) – Alternative Cap	0.016	0.031
Final Cover Condition (Side Slopes) – Alternative Cap	0.032	0.064

1. All scenarios shown with 100 percent recirculation of leachate collected from the liner.

3I.2.2 Leachate Collection

Leachate Collection System Design

The leachate collection system was designed in accordance with 30 TAC §330.331(a)(2) and §330.333. The leachate collection system and piping must be:

- Designed to maintain less than 30-centimeters (12-inches) of leachate depth over the liner;
- Made of materials that are chemically resistant. The leachate collection system materials shall be constructed of high density poly-ethylene (HDPE);
- Of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, cover materials, and any equipment; and
- Designed and operated to function through the scheduled closure and post-closure care period.

The system design shall consist of the following components:

- Estimated rate of leachate removal from the sump;
- Capacity of the sump;
- Pipe material and strength;
- Pipe network spacing and grading;
- Collection sump materials and strength;

- Drainage media specifications and performance; and,
- Demonstrate that pipes and perforations will be resistant to clogging and can be cleaned.

These design requirements are discussed in further detail in the sections below. Leachate collection system details are provided on Drawing P3-31 in Appendix 3G.

Leachate Collection Layer

30 TAC §330.333(3)(D) and (F)

The leachate collection layer consist of ~~2 feet of~~ ***a 24-inch sand protective layer (***drainage material***)*** overlying the geomembrane liner. The drainage material will have a minimum coefficient of permeability of 1.0×10^{-3} cm/sec. The effectiveness of this drainage layer is demonstrated in the HELP model analyses completed in Attachment 1 in Appendix 3I. The leachate collection layer will slope at a minimum of one-percent to the leachate collection trench and pipe (maximum of 600-feet).

Existing Sector K sand was also constructed to have a minimum coefficient of permeability of 1.0×10^{-3}cm/sec.

Leachate Aggregate

As outlined in the drawings, the leachate aggregate shall consist of 12-inches of 1 ½-inch washed aggregate and 12-inches of pea-gravel. The aggregate gradation change is implemented to substitute using a geotextile to encase the aggregate, which can be a clogging potential long-term.

The 1 ½-inch washed aggregate backfill shall meet the following specifications:

- Clean, washed, non-carbonate, sub-angular to rounded material, bank run gravel with no organic matter. Crushed aggregate, concrete, bituminous, or limestone not allowed. Soil Classification of GW or GP;
- Meeting the following Gradation (ASTM D422):
  1. 100% passing 1 ½-inch sieve
  2. 0% passing ¾-inch sieve

The pea-gravel backfill shall meet the following specifications:

- Durable washed, non-carbonate, coarse-rounded to sub-angular gravel exhibiting the following relationship to the drainage sand layer:
  1. D15 (Pea-gravel)/D85 (Drainage Sand) < 4 to 5
  2. D15 (Pea-gravel)/D15 (Drainage Sand) < 20
     - Where D_{15} and D_{85} are the diameters which 15% and 85% by weight (respectively) are finer.

Leachate Collection Trenches and Piping

30 TAC §330.333(2) and §330.333(3)(C), (E) and (G)

The leachate collection trenches will slope at a minimum of one-percent to the leachate collection sumps. The leachate collection piping will be placed at the center of the leachate collection trench and will be required to meet the following specifications:

- HDPE pipe designated as PE 3408;
- SDR 9 for perforated leachate collection pipe in trenches (8-inch), cleanout riser pipes (8-inch), and for side-slope riser (SSR) pipes (18-inch);
- Maximum deflection of five percent;
- Pipe perforations for leachate collection piping: ½-inch in diameter, 90-degrees apart symmetrical around the pipe, 5-inch linear spacing (Drawing P3-31 in Appendix 3G); and
- Pipe perforations for sump collection piping: ½-inch in diameter, 45-degrees apart symmetrical around the pipe, 3-inch linear spacing (Drawing P3-32 in Appendix 3G).

Calculations for wall crushing, wall buckling, and ring deflection based on the above design parameters are provided in Attachment 2 in Appendix 3I. Calculations show that the ~~proposed~~ leachate collection systems are of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, waste cover materials, and by any equipment used at the landfill.

Pipe strength calculations were performed separately for the existing lined Phase I/II area (Sector K) to check the pipe strength of the existing pipe in place (6" SDR 11 HDPE pipe). The Sector K pipe calculations are also provided in Appendix 3I, Attachment 2. Calculations show that the existing pipe meets or exceeds the wall crushing, wall buckling and ring deflection requirements for all but the Watkins-Gaube ring deflection. The Watkins-Gaube ring deflection was calculated at 5.15% deflection, which is slightly over the recommended maximum deflection (5%) but under the allowable deflection (7.5%). The pipe is considered to be of sufficient strength and thickness to prevent collapse under the pressures exerted by the additional overlying wastes and waste cover materials for Sector K. Equipment calculations were not provided for Sector K as the critical time for equipment operations over pipe is during the initial lifts of waste being placed in the cell and Sector K already has approximately 50-feet of waste in place to help prevent collapse from equipment.

All leachate piping will have an attached pipe that leads to a reachable point so that the pipe is able to be accessed for cleaning (detail provided on Drawing P3-31 in Appendix 3G).

Geotextile Cushion

Cushion geotextile will be placed between the geomembrane and the leachate collection backfill (and piping) for puncture protection. The geotextile cushion layer shall be a non-woven polypropylene or polyester fabric required to meet the following specifications:

- Fabric Weight: 16 oz per square yard minimum;
- Puncture Resistance: 240 lbs (ASTM D-4833);

Geotextiles will be required to have a sewn seam or an 18-inch minimum sheet overlap.

Leachate Sump and Pump

30 TAC §330.333(3)(A) and (B)

The leachate sump will consist of a 3-foot deep rectangular area. The sump will have a minimum nominal dimension of 8-foot by 8-foot at the base and 26-foot by 26-foot at the top; for a minimum volume of 948 cubic feet (CF). The capacity of the sump has been selected to limit the maximum head on the liner. The media within the sump is to meet the same specifications as that of the 1½-inch aggregate specified for leachate collection aggregate. The average porosity for this aggregate is assumed to be 30%. Based on the porosity, 284 CF (2,124 gallons) in the sump will be available for leachate storage.

Based on the HELP model, the average yearly leachate generation rate for the open condition (maximum leachate generation) is 418 CF/acre/year (or 0.2 gallons per minute (gpm) based on the largest designed sector of 39-acres). Therefore, the recommended pumping size is from 5 gpm to 10 gpm to allow for periodic increases in precipitation.

The pumps will be operated by level transducers to ensure that leachate head does not exceed 12-inches over the liner (or approximately 48-inches in the sump, dependent on actual construction). Transducers will cycle on at approximately 36-inches of head within the sump (or 0-inches of head on the liner) and cycle off at approximately 6-inches of head within the sump. The pump hour reading will be recorded on a quarterly basis and kept in the Site Operating Record.

The leachate sump for Sector K was designed to have a nominal dimension of 7-foot by 7-foot at the base and 21-foot by 21-foot at the top; for a minimum volume of 735 cubic feet (CF). The average porosity for the aggregate is assumed to be 30%. Based on the porosity, 221 CF (1,653 gallons) in the sump are available for leachate storage. Based on the HELP model, the average yearly leachate generation rate for the open condition is 418 CF/acre/year (or 0.1 gpm based on Sector K size of 16.95 acres).

3I.2.3 Leachate Storage

Leachate will be stored within the leachate sump and within the waste mass on site.

3I.2.4 Leachate Disposal

Leachate will be disposed of within the waste mass on site.

3I.2.5 Leachate Recirculation

Leachate removed from the sumps will be recirculated within the waste mass. As shown in the HELP model results in Attachment 1 in Appendix 3I, 100% of the leachate can be recirculated back into the waste mass, while still maintaining less than 12-inches of leachate head on the liner.

The volume of leachate removed and recirculated, based on the sump pump hour meter reading, will be recorded quarterly in the Site Operating Record. Periodic analysis of leachate quality will also be placed in the Site Operating Record.

3I.3 Contaminated Water Management

The Contaminated Water Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) is included in partial form for compliance with 30 TAC §330.305 (b) and (c) Attachment 3 in Appendix 3I. No changes are recommended from this design.

Stormwater that comes into contact with the active working face and is not contained within the site run-on/runoff berms will be managed in the following manner:

- Contaminated water will be contained as best possible within site sedimentation basins or other low-lying areas onsite;
- Testing will be completed on the contaminated water in accordance with the site SWPPP; and
- If testing indicates that the water is contaminated, it will be pumped out of the containment area into a tanker truck and transferred to the El Paso Waste Water Treatment Plant.

Any water that infiltrates or evaporates prior to being transferred offsite shall be considered mitigated or controlled and no further action will be taken.

3I.4 Gas Condensate Management

If gas condensate is produced, it will be stored and disposed of as leachate.

3I.1 Introduction

This Leachate and Contaminated Water Plan has been developed in accordance with 30 TAC §330.65(c), §330.177, §330.207, §330.331(a)(2), and §330.333 for the McCombs Landfill (Landfill) located in El Paso, TX. This plan provides details of the collection, storage, and disposal of contaminated water, leachate, and gas condensate from the leachate collection system, gas monitoring and collection systems, and site operations.

3I.1.1 Definitions

Definitions for the following have been defined by TAC §330.3.

- (36) Contaminated Water – "Leachate, gas condensate, or water that has come into contact with waste."
- (57) Gas Condensate – "The liquid generated as a result of any gas recovery process at a municipal solid waste facility."
- (78) Leachate – "A liquid that has passed through or emerged from solid waste and contains soluble, suspended, or miscible materials removed from such waste"

3I.2 Leachate Management

The Leachate Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) was used to assist in the development of the following section ***and is provided in partial form as Appendix 3I, Attachment 3. Sections, Figures and Appendices not provided have been updated within***.

3I.2.1 Leachate Generation

Leachate generation was estimated by running the Hydrologic Evaluation of Landfill Performance (HELP) Model, Version 3.07. The HELP model is a program that computes the water balance for municipal landfills based on weather, soil, and design data and uses solution techniques that account for the effects of surface storage, runoff, infiltration, evapotranspiration, vegetation, soil moisture storage, subsurface drainage, recirculation, and leakage.

The climate data for the simulations was synthetically generated using coefficients for El Paso, Texas. The various conditions modeled were as follows:

1. All scenarios shown with 100 percent recirculation of leachate collected from the liner.

3I.2.2 Leachate Collection

Leachate Collection System Design

The leachate collection system was designed in accordance with 30 TAC §330.331(a)(2) and §330.333. The leachate collection system and piping must be:

- Designed to maintain ~~a minimum of~~ ***less than*** 30-centimeters (12-inches) of leachate depth over the liner;
- Made of materials that are chemically resistant. The leachate collection system materials shall be constructed of high density poly-ethylene (HDPE);
- Of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, cover materials, and any equipment; and
- Designed and operated to function through the scheduled closure and post-closure care period.

The system design shall consist of the following components:

- Estimated rate of leachate removal from the sump;
- Capacity of the sump;
- Pipe material and strength;
- Pipe network spacing and grading;
- Collection sump materials and strength;
- Drainage media specifications and performance; and,

- Demonstrate that pipes and perforations will be resistant to clogging and can be cleaned.

These design requirements are discussed in further detail in the sections below. Leachate collection system details are provided on Drawing P3-31 in Appendix 3G.

Leachate Collection Layer

30 TAC §330.333(3)(D) and (F)

The leachate collection layer consist of 2-feet of drainage material overlying the geomembrane liner. The drainage material will have a minimum coefficient of permeability of 1.0 x 10^{-3} cm/sec. The effectiveness of this drainage layer is demonstrated in the HELP model analyses completed in Attachment 1 in Appendix 3I. The leachate collection layer will slope at a minimum of one-percent to the leachate collection trench and pipe (maximum of 600-feet).

Existing Sector K sand was also constructed to have a minimum coefficient of permeability of 1.0 x 10^{-3} cm/sec.

Leachate Aggregate

As outlined in the drawings, the leachate aggregate shall consist of 12-inches of 1 ½-inch washed aggregate and 12-inches of pea-gravel. The aggregate gradation change is implemented to substitute using a geotextile to encase the aggregate, which can be a clogging potential long-term.

The 1 ½-inch washed aggregate backfill shall meet the following specifications:

- Clean, washed, non-carbonate, sub-angular to rounded material, bank run gravel with no organic matter. Crushed aggregate, concrete, bituminous, or limestone not allowed. Soil Classification of GW or GP;
- Meeting the following Gradation (ASTM D422):
  1. 100% passing 1 ½-inch sieve
  2. 0% passing ¾-inch sieve

The pea-gravel backfill shall meet the following specifications:

- Durable washed, non-carbonate, coarse-rounded to sub-angular gravel exhibiting the following relationship to the drainage sand layer:
  1. D15 (Pea-gravel)/D85 (Drainage Sand) < 4 to 5
  2. D15 (Pea-gravel)/D15 (Drainage Sand) < 20
     - Where D_{15} and D_{85} are the diameters which 15% and 85% by weight (respectively) are finer.

Leachate Collection Trenches and Piping

30 TAC §330.333(2) and §330.333(3)(C), (E) and (G)

The leachate collection trenches will slope at a minimum of one-percent to the leachate collection sumps. The leachate collection piping will be placed at the center of the leachate collection trench and will be required to meet the following specifications:

- HDPE pipe designated as PE 3408;
- SDR 9 for perforated leachate collection pipe in trenches (8-inch), cleanout riser pipes (8-inch), and for side-slope riser (SSR) pipes (18-inch);
- Maximum deflection of five percent;
- Pipe perforations for leachate collection piping: ½-inch in diameter, 90-degrees apart symmetrical around the pipe, 5-inch linear spacing (Drawing P3-31 in Appendix 3G); and
- Pipe perforations for sump collection piping: ½-inch in diameter, 45-degrees apart symmetrical around the pipe, 3-inch linear spacing (Drawing P3-32 in Appendix 3G).

Calculations for wall crushing, wall buckling, and ring deflection based on the above design parameters are provided in Attachment 2 in Appendix 3I. ***Calculations show that the proposed leachate collection systems are of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, waste cover materials, and by any equipment used at the landfill.***

Pipe strength calculations were performed separately for the existing lined Phase I/II area (Sector K) to check the pipe strength of the existing pipe in place (6" SDR 11 HDPE pipe). The Sector K pipe calculations are also provided in Appendix 3I, Attachment 2. Calculations show that the existing pipe meets or exceeds the wall crushing, wall buckling and ring deflection requirements for all but the Watkins-Gaube ring deflection. The Watkins-Gaube ring deflection was calculated at 5.15% deflection, which is slightly over the recommended maximum deflection (5%) but under the allowable deflection (7.5%). The pipe is considered to be of sufficient strength and thickness to prevent collapse under the pressures exerted by the additional overlying wastes and waste cover materials for Sector K. Equipment calculations were not provided for Sector K as the critical time for equipment operations over pipe is during the initial lifts of waste being placed in the cell and Sector K already has approximately 50-feet of waste in place to help prevent collapse from equipment.

All leachate piping will have an attached pipe that leads to a reachable point so that the pipe is able to be accessed for cleaning (detail provided on Drawing P3-31 in Appendix 3G).

Geotextile Cushion

Cushion geotextile will be placed between the geomembrane and the leachate collection backfill (and piping) for puncture protection. The geotextile cushion layer shall be a non-woven polypropylene or polyester fabric required to meet the following specifications:

- Fabric Weight: 16 oz per square yard minimum;
- Puncture Resistance: 240 lbs (ASTM D-4833);

Geotextiles will be required to have a sewn seam or an 18-inch minimum sheet overlap.

Leachate Sump and Pump

30 TAC §330.333(3)(A) and (B)

The leachate sump will consist of a 3-foot deep rectangular area. The sump will have a minimum nominal dimension of 8-foot by 8-foot at the base and 26-foot by 26-foot at the top; for a minimum volume of 948 cubic feet (CF). The capacity of the sump has been selected to limit the maximum head on the liner. The media within the sump is to meet the same specifications as that of the 1½-inch aggregate specified for leachate collection aggregate. The average porosity for this aggregate is assumed to be 30%. Based on the porosity, 284 CF (2,124 gallons) in the sump will be available for leachate storage.

Based on the HELP model, the average yearly leachate generation rate for the open condition (maximum leachate generation) is ***418*** ~~1,593~~ CF/acre/year (or ***0.2*** ~~1.0~~ gallons per minute (gpm) based on the largest designed sector of 39-acres). Therefore, the recommended pumping size is from 5 gpm to 10 gpm to allow for periodic increases in precipitation.

The pumps will be operated by level transducers to ensure that leachate head does not exceed 12-inches over the liner (or approximately 48-inches in the sump, dependent on actual construction). Transducers will cycle on at approximately 36-inches of head within the sump (or 0-inches of head on the liner) and cycle off at approximately 6-inches of head within the sump. The pump hour reading will be recorded on a quarterly basis and kept in the Site Operating Record.

The leachate sump for Sector K was designed to have a nominal dimension of 7-foot by 7-foot at the base and 21-foot by 21-foot at the top; for a minimum volume of 735 cubic feet (CF). The average porosity for the aggregate is assumed to be 30%. Based on the porosity, 221 CF (1,653 gallons) in the sump are available for leachate storage. Based on the HELP model, the average yearly leachate generation rate for the open condition is 418 CF/acre/year (or 0.1 gpm based on Sector K size of 16.95 acres).

3I.2.3 Leachate Storage

Leachate will be stored within the leachate sump and within the waste mass on site.

3I.2.4 Leachate Disposal

Leachate will be disposed of within the waste mass on site.

3I.2.5 Leachate Recirculation

Leachate removed from the sumps will be recirculated within the waste mass. As shown in the HELP model results in Attachment 1 in Appendix 3I, 100% of the leachate can be recirculated back into the waste mass, while still maintaining less than 12-inches of leachate head on the liner.

The volume of leachate removed and recirculated, based on the sump pump hour meter reading, will be recorded ***quarterly*** ~~monthly~~ in the Site Operating Record. Periodic analysis of leachate quality will also be placed in the Site Operating Record.

3I.3 Contaminated Water Management

The Contaminated Water Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) is included in ***partial form for compliance with 30 TAC §330.305 (b) and (c)*** Attachment 3 in Appendix 3I. No changes are recommended from this design.

Stormwater that comes into contact with the active working face and is not contained within the site run-on/runoff berms will be managed in the following manner:

- ***Contaminated water will be contained as best possible within site sedimentation basins or other low-lying areas onsite;***
- ***Testing will be completed on the contaminated water in accordance with the site SWPPP; and***
- ***If testing indicates that the water is contaminated, it will be pumped out of the containment area into a tanker truck and transferred to the El Paso Waste Water Treatment Plant.***

Any water that infiltrates or evaporates prior to being transferred offsite shall be considered mitigated or controlled and no further action will be taken.

3I.4 Gas Condensate Management

If gas condensate is produced, it will be stored and disposed of as leachate.

TITLE: OPEN CONDITIONS - 10FT MSW 6" DAILY COVER_ALT LINER

****

NOTE: INITIAL MOISTURE CONTENT OF THE LAYERS AND SNOW WATER WERE
COMPUTED AS NEARLY STEADY-STATE VALUES BY THE PROGRAM.

LAYER 1

TYPE 1 - VERTICAL PERCOLATION LAYER
MATERIAL TEXTURE NUMBER 6

THICKNESS	=	6.00	INCHES
POROSITY	=	0.4530	VOL/VOL
FIELD CAPACITY	=	0.1900	VOL/VOL
WILTING POINT	=	0.0850	VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.2098	VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.720000011000E-03	CM/SEC

NOTE: 100.00 PERCENT OF THE DRAINAGE COLLECTED FROM LAYER # 4
IS RECIRCULATED INTO THIS LAYER.

LAYER 2

TYPE 1 - VERTICAL PERCOLATION LAYER
MATERIAL TEXTURE NUMBER 18

THICKNESS	=	120.00 INCHES
POROSITY	=	0.6710 VOL/VOL
FIELD CAPACITY	=	0.2920 VOL/VOL
WILTING POINT	=	0.0770 VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.2697 VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.100000005000E-02 CM/SEC

LAYER 3

TYPE 1 - VERTICAL PERCOLATION LAYER
MATERIAL TEXTURE NUMBER 0

THICKNESS	=	12.00 INCHES
POROSITY	=	0.4370 VOL/VOL
FIELD CAPACITY	=	0.0620 VOL/VOL
WILTING POINT	=	0.0240 VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.1074 VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.100000005000E-02 CM/SEC

LAYER 4

TYPE 2 - LATERAL DRAINAGE LAYER
MATERIAL TEXTURE NUMBER 0

THICKNESS	=	12.00 INCHES
POROSITY	=	0.4370 VOL/VOL
FIELD CAPACITY	=	0.0620 VOL/VOL
WILTING POINT	=	0.0240 VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.0932 VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.100000005000E-02 CM/SEC
SLOPE	=	1.00 PERCENT
DRAINAGE LENGTH	=	350.0 FEET

NOTE: 100.00 PERCENT OF THE DRAINAGE COLLECTED FROM THIS LAYER IS RECIRCULATED INTO LAYER # 1.

LAYER 5

TYPE 4 - FLEXIBLE MEMBRANE LINER
MATERIAL TEXTURE NUMBER 35

THICKNESS	=	0.06 INCHES
POROSITY	=	0.0000 VOL/VOL
FIELD CAPACITY	=	0.0000 VOL/VOL
WILTING POINT	=	0.0000 VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.0000 VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.199999996000E-12 CM/SEC
FML PINHOLE DENSITY	=	1.00 HOLES/ACRE
FML INSTALLATION DEFECTS	=	2.00 HOLES/ACRE
FML PLACEMENT QUALITY	=	3 - GOOD

LAYER 6

TYPE 3 - BARRIER SOIL LINER
MATERIAL TEXTURE NUMBER 0

THICKNESS	=	0.24	INCHES
POROSITY	=	0.7500	VOL/VOL
FIELD CAPACITY	=	0.7470	VOL/VOL
WILTING POINT	=	0.4000	VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.7500	VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.499999997000E-08	CM/SEC

LAYER 7

TYPE 1 - VERTICAL PERCOLATION LAYER
MATERIAL TEXTURE NUMBER 2

THICKNESS	=	6.00	INCHES
POROSITY	=	0.4370	VOL/VOL
FIELD CAPACITY	=	0.0620	VOL/VOL
WILTING POINT	=	0.0240	VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.0610	VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.579999993000E-02	CM/SEC

GENERAL DESIGN AND EVAPORATIVE ZONE DATA

NOTE: SCS RUNOFF CURVE NUMBER WAS COMPUTED FROM DEFAULT SOIL DATA BASE USING SOIL TEXTURE # 6 WITH BARE GROUND CONDITIONS, A SURFACE SLOPE OF 2.% AND A SLOPE LENGTH OF 2000. FEET.

SCS RUNOFF CURVE NUMBER	=	84.20	
FRACTION OF AREA ALLOWING RUNOFF	=	0.0	PERCENT
AREA PROJECTED ON HORIZONTAL PLANE	=	1.000	ACRES
EVAPORATIVE ZONE DEPTH	=	24.0	INCHES
INITIAL WATER IN EVAPORATIVE ZONE	=	3.839	INCHES
UPPER LIMIT OF EVAPORATIVE STORAGE	=	14.796	INCHES
LOWER LIMIT OF EVAPORATIVE STORAGE	=	1.896	INCHES
INITIAL SNOW WATER	=	0.000	INCHES
INITIAL WATER IN LAYER MATERIALS	=	36.576	INCHES
TOTAL INITIAL WATER	=	36.576	INCHES
TOTAL SUBSURFACE INFLOW	=	0.00	INCHES/YEAR

EVAPOTRANSPIRATION AND WEATHER DATA

NOTE: EVAPOTRANSPIRATION DATA WAS OBTAINED FROM
EL PASO TEXAS

STATION LATITUDE = 31.80 DEGREES

MAXIMUM LEAF AREA INDEX	=	0.00
START OF GROWING SEASON (JULIAN DATE)	=	66
END OF GROWING SEASON (JULIAN DATE)	=	315
EVAPORATIVE ZONE DEPTH	=	24.0 INCHES
AVERAGE ANNUAL WIND SPEED	=	9.20 MPH
AVERAGE 1ST QUARTER RELATIVE HUMIDITY	=	40.00 %
AVERAGE 2ND QUARTER RELATIVE HUMIDITY	=	27.00 %
AVERAGE 3RD QUARTER RELATIVE HUMIDITY	=	46.00 %
AVERAGE 4TH QUARTER RELATIVE HUMIDITY	=	48.00 %

NOTE: PRECIPITATION DATA WAS SYNTHETICALLY GENERATED USING
COEFFICIENTS FOR EL PASO TEXAS

NORMAL MEAN MONTHLY PRECIPITATION (INCHES)

JAN/JUL	FEB/AUG	MAR/SEP	APR/OCT	MAY/NOV	JUN/DEC
0.38	0.45	0.32	0.19	0.24	0.56
1.60	1.21	1.42	0.73	0.33	0.39

NOTE: TEMPERATURE DATA WAS SYNTHETICALLY GENERATED USING
COEFFICIENTS FOR EL PASO TEXAS

NORMAL MEAN MONTHLY TEMPERATURE (DEGREES FAHRENHEIT)

JAN/JUL	FEB/AUG	MAR/SEP	APR/OCT	MAY/NOV	JUN/DEC
44.20	48.40	55.10	63.60	71.90	80.80
82.50	80.30	74.10	63.60	51.40	44.40

NOTE: SOLAR RADIATION DATA WAS SYNTHETICALLY GENERATED USING
COEFFICIENTS FOR EL PASO TEXAS
AND STATION LATITUDE = 31.80 DEGREES
