[A] – Net Volume less 60-inches (36-inches for prescriptive final cover and 24-inches for protective cover). Sector A volume only less 36-inches for prescriptive final cover.

[B] – Net Volume less 52-inches (24-inches for alternative final cover and 28-inches for protective cover). Sector A volume only less 28-inches for alternative final cover.

[C] – Volumes include intermediate cover.

SAIC®

Appendix 3H
SITE LIFE PROJECTIONS

3H.1 Solid Waste Generation

The McCombs Landfill accepts waste generated in El Paso County, Texas. The Clint Landfill also accepts waste generated in El Paso County. The estimated rate of disposal was calculated assuming an annual population increase of 2% in growth, and assuming a disposal rate of 497,309 tons per year (in 2014 tonnage) until Clint Landfill closes in 2030. 3,000 tons per year are assumed from 2011 through 2013. After Clint Landfill closes, McCombs Landfill will receive all of the waste that would have previously gone to Clint Landfill, therefore the disposal rate at McCombs will raise from 45% of the county waste allocation to 100%. The 1990 base population for central, northeastern and northwestern areas of El Paso (areas where solid waste is planned to go to the McCombs Landfill) was used for the growth rate estimation. The population for the above mentioned areas in 1990 was 322,842 people.

The disposal rate for C&D waste was calculated assuming a disposal rate of 60,000 tons per year (this is the approximate tonnage of C&D disposed of at Clint Landfill 2284 in FY 2010), also with an annual increase of 2% growth.

3H.2 Airspace utilization

An airspace utilization factor (AUF) of 0.60 tons per cubic yard (1200 pounds per cubic yard) of landfill airspace was utilized to calculate the site life projections for the volume available at the McCombs Landfill.

3H.3 Landfill Capacity

The total landfill capacity represents a total volume available for disposal of solid waste, daily cover material and intermediate cover material. AutoCAD Civil 3D 2011 computer software was utilized to estimate the total capacity. The total capacity is defined as the volume between the top of the geomembrane on the cell liner system and top of the final cover system. Sector A is currently being filled with waste so the existing capacity in that sector was evaluated between the existing contours in that sector and the top of the final cover system of that sector.

The total remaining landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including waste and daily, intermediate and final cover), which provides capacity through 2014 based on Table 3H-1. The total remaining landfill volume available for waste disposal, protective soil and daily, intermediate and final cover (including the remainder of Sector A) and all subsequent planned sectors (B through K) is ~~62,853,182~~ ***63,469,470*** CY. The total remaining volume for waste disposal including intermediate cover using the prescriptive final cover profile is ~~60,675,743~~ ***61,292,030*** CY. The total volume remaining for waste disposal including intermediate cover utilizing the alternative final cover profile is

~~60,973,535~~ ***61,589,822*** CY. The sector development plan can be seen in Appendix 3E - Site Layout Plans, Drawing P3-16 - Landfill Completion Plan.

3H.4 Site Life Calculations

Using the rate of 2% growth per year, an AUF of 1200 lb/cy for MSW and 1800 lb/cy for C&D, an increase in waste received after 2030, and the remaining capacity above, the remaining estimated life of the Landfill is until 2059 for both prescriptive and alternative final cover profiles. See Table 3H-1 and Table 3H-2 for MSW Prescriptive and Alternative Site Life Calculations and Table 3H-3 for C&D Site Life Calculations. See Table 3H-4 for Sector Volume Calculations.

Total C&D	2,930,931.26	67.28	2,072,752		NA		NA	

[A] – Net Volume less 60-inches (36-inches for prescriptive final cover and 24-inches for protective cover). Sector A volume only less 36-inches for prescriptive final cover.

[B] – Net Volume less 52-inches (24-inches for alternative final cover and 28-inches for protective cover). Sector A volume only less 28-inches for alternative final cover.

[C] – Volumes include intermediate cover.

Appendix 3H
SITE LIFE PROJECTIONS

3H.1 Solid Waste Generation

The McCombs Landfill accepts waste generated in El Paso County, Texas. The Clint Landfill also accepts waste generated in El Paso County. The estimated rate of disposal was calculated assuming an annual population increase of 2% in growth, and assuming a disposal rate of 497,309 tons per year (in 2014 tonnage) until Clint Landfill closes in 2030. 3,000 tons per year are assumed from 2011 through 2013. After Clint Landfill closes, McCombs Landfill will receive all of the waste that would have previously gone to Clint Landfill, therefore the disposal rate at McCombs will raise from 45% of the county waste allocation to 100%. The 1990 base population for central, northeastern and northwestern areas of El Paso (areas where solid waste is planned to go to the McCombs Landfill) was used for the growth rate estimation. The population for the above mentioned areas in 1990 was 322,842 people.

The disposal rate for C&D waste was calculated assuming a disposal rate of 60,000 tons per year (this is the approximate tonnage of C&D disposed of at Clint Landfill 2284 in FY 2010), also with an annual increase of 2% growth.

3H.2 Air Apace utilization

An airspace utilization factor (AUF) of 0.60 tons per cubic yard (1200 pounds per cubic yard) of landfill airspace was utilized to calculate the site life projections for the volume available at the McCombs Landfill.

3H.3 Landfill Capacity

The total landfill capacity represents a total volume available for disposal of solid waste, daily cover material and intermediate cover material. AutoCAD Civil 3D 2011 computer software was utilized to estimate the total capacity. The total capacity is defined as the volume between the top of the geomembrane on the cell liner system and top of the final cover system. Sector A is currently being filled with waste so the existing capacity in that sector was evaluated between the existing contours in that sector and the top of the final cover system of that sector.

The total remaining landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including ~~both~~ waste and daily, intermediate and final cover), which provides capacity through 2014 based on Table 3H-1. The total remaining landfill volume available for waste disposal, protective soil and daily, intermediate and final cover (including the remainder of Sector A) and all subsequent planned sectors (B through K) is ~~62,532,764~~***62,853,182*** CY. The total remaining volume for waste disposal including intermediate cover using the prescriptive final cover profile is ~~60,355,32~~***60,675,743*** CY. The total volume remaining for waste disposal including intermediate cover utilizing the alternative final cover profile is

~~60,653,116~~***60,973,535*** CY. The sector development plan can be seen in Appendix 3E - Site Layout Plans, Drawing P3-16 - Landfill Completion Plan.

3H.4 Site Life Calculations

Using the rate of 2% growth per year, an AUF of 1200 lb/cy for MSW and 1800 lb/cy for C&D, an increase in waste received after 2030, and the remaining capacity above, the remaining estimated life of the Landfill is until 2059 for both prescriptive and alternative final cover profiles. See Table 3H-1 and Table 3H-2 for MSW Prescriptive and Alternative Site Life Calculations and Table 3H-3 for C&D Site Life Calculations. See Table 3H-4 for Sector Volume Calculations.

Total A-K	12,060,576	276.87	~~62,532,764~~*62,853,182*	~~60,355,324~~*60,675,743*	~~60,653,116~~*60,973,535*
Total C&D	2,930,931.26	67.28	~~2,581,306~~*2,072,752*	NA	NA

[A] – Net Volume less 60-inches (36-inches for prescriptive final cover and 24-inches for protective cover). Sector A volume only less 36-inches for prescriptive final cover.

[B] – Net Volume less 52-inches (24-inches for alternative final cover and 28-inches for protective cover). Sector A volume only less 28-inches for alternative final cover.

[C] – *Volumes include intermediate cover.*

Appendix 3H
SITE LIFE PROJECTIONS

3H.1 Solid Waste Generation

The McCombs Landfill accepts waste generated in El Paso County, Texas. The Clint Landfill also accepts waste generated in El Paso County. The estimated rate of disposal was calculated assuming an annual population increase of 2% in growth, and assuming a disposal rate of 497,309 tons per year (in 2014 tonnage) until Clint Landfill closes in 2030. 3,000 tons per year are assumed from 2011 through 2013. After Clint Landfill closes, McCombs Landfill will receive all of the waste that would have previously gone to Clint Landfill, therefore the disposal rate at McCombs will raise from 45% of the county waste allocation to 100%. The 1990 base population for central, northeastern and northwestern areas of El Paso (areas where solid waste is planned to go to the McCombs Landfill) was used for the growth rate estimation. The population for the above mentioned areas in 1990 was 322,842 people.

The disposal rate for C&D waste was calculated assuming a disposal rate of 60,000 tons per year (this is the approximate tonnage of C&D disposed of at Clint Landfill 2284 in FY 2010), also with an annual increase of 2% growth.

3H.2 Air Apace utilization

An airspace utilization factor (AUF) of 0.60 tons per cubic yard (1200 pounds per cubic yard) of landfill airspace was utilized to calculate the site life projections for the volume available at the McCombs Landfill.

3H.3 Landfill Capacity

The total landfill capacity represents a total volume available for disposal of solid waste, daily cover material and intermediate cover material. AutoCAD Civil 3D 2011 computer software was utilized to estimate the total capacity. The total capacity is defined as the volume between the top of the ***geomembrane*** ~~protective soil layer~~ on the cell liner system and ***top*** ~~bottom~~ of the final cover system. Sector A is currently being filled with waste so the existing capacity in that sector was evaluated between the existing contours in that sector and the ***top*** ~~bottom~~ of the final cover system of that sector.

The total remaining landfill volume available for waste disposal in Sector A is approximately 640,890 cubic yards (including ~~both~~ waste and daily***, intermediate and final*** cover), which provides capacity through 2014 based on Table 3H-1. The total remaining landfill volume available for waste disposal***, protective soil and daily, intermediate and final cover (***including the remainder of Sector A***)*** and all subsequent planned sectors (B through K) is 62,532,764 CY. ***The total remaining volume for waste disposal using the prescriptive final cover profile is 60,355,324 CY. The total volume remaining for waste disposal utilizing the alternative final cover profile is***

60,653,116 CY. The sector development plan can be seen in Appendix 3E - Site Layout Plans, Drawing P3-16 - Landfill Completion Plan.

3H.4 Site Life Calculations

Using the rate of 2% growth per year, an AUF of 1200 lb/cy ***for MSW and 1800 lb/cy for C&D***, an increase in waste received after 2030, and the remaining capacity above, the remaining estimated life of the Landfill is ***until 2059 for both prescriptive and alternative final cover profiles*** ~~49 years~~. See Table 3H-1 and Table 3H-2 for MSW ***Prescriptive and Alternative*** ~~and C&D~~ Site Life Calculations ***and Table 3H-3 for C&D Site Life Calculations***. See Table 3H-~~3~~***4*** for Sector Volume Calculations.

3I.1 Introduction

This Leachate and Contaminated Water Plan has been developed in accordance with 30 TAC §330.65(c), §330.177, §330.207, §330.331(a)(2), and §330.333 for the McCombs Landfill (Landfill) located in El Paso, TX. This plan provides details of the collection, storage, and disposal of contaminated water, leachate, and gas condensate from the leachate collection system, gas monitoring and collection systems, and site operations.

3I.1.1 Definitions

Definitions for the following have been defined by TAC §330.3.

- (36) Contaminated Water – "Leachate, gas condensate, or water that has come into contact with waste."
- (57) Gas Condensate – "The liquid generated as a result of any gas recovery process at a municipal solid waste facility."
- (78) Leachate – "A liquid that has passed through or emerged from solid waste and contains soluble, suspended, or miscible materials removed from such waste."

3I.2 Leachate Management

The Leachate Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) was used to assist in the development of the following section and is provided in partial form as Appendix 3I, Attachment 3. Sections, Figures and Appendices not provided have been updated within.

3I.2.1 Leachate Generation

Leachate generation was estimated by running the Hydrologic Evaluation of Landfill Performance (HELP) Model, Version 3.07. The HELP model is a program that computes the water balance for municipal landfills based on weather, soil, and design data and uses solution techniques that account for the effects of surface storage, runoff, infiltration, evapotranspiration, vegetation, soil moisture storage, subsurface drainage, recirculation, and leakage.

The climate data for the simulations was synthetically generated using coefficients for El Paso, Texas. The various conditions modeled were as follows:

Table 3I-1
HELP Modeling Methodology/Assumptions

Scenario	Open Condition (Daily Cover)	Intermediate Cover Condition	Final Cover Condition (Crown)	Final Cover Condition (Side-Slopes)	Final Cover Condition (Crown) – Alt. Cap	Final Cover Condition (Side-Slopes) – Alt. Cap
Subgrade	6-Inch Compacted Native Soil	6-Inch Compacted Native Soil	6-Inch Compacted Native Soil	6-Inch Compacted Native Soil	6-Inch Compacted Native Soil	6-Inch Compacted Native Soil
Low Perm Layer	GCL or 6-inch Barrier Soil[1]	GCL	GCL	GCL	GCL	GCL
Base Geomembrane	60-mil HDPE	60-mil HDPE	60-mil HDPE	60-mil HDPE	60-mil HDPE	60-mil HDPE
Protective Soil Layer	2-Feet Drainage Sand ($1.0x10^{-3}$ cm/sec)	2-Feet Drainage Sand ($1.0x10^{-3}$ cm/sec)	2-Feet Drainage Sand ($1.0x10^{-3}$ cm/sec)	2-Feet Drainage Sand ($1.0x10^{-3}$ cm/sec)	2-Feet Drainage Sand ($5.8x10^{-3}$ cm/sec)	2-Feet Drainage Sand ($5.8x10^{-3}$ cm/sec)
Waste Depth	10-Feet	264-Feet	264-Feet	214-Feet	264-Feet	214-Feet
Cover Soil	6-Inches Daily	12-Inches Intermediate	12-Inches Intermediate	12-Inches Intermediate	12-Inches Intermediate	12-Inches Intermediate
Infiltration (Support) Layer	None	None	18-Inch Layer ($1x10^{-5}$ cm/sec)	18-Inch Layer ($1x10^{-5}$ cm/sec)	6-Inch Layer	6-Inch Layer
Final Cover Geomembrane	None	None	40-mil LLDPE	40-mil LLDPE	None	None
Erosion Layer	None	None	12-Inches	12-Inches	18-Inches	18-Inches
Topsoil	None	None	6-Inches	6-Inches	4-Inches Rock	4-Inches Rock
Ground Cover	Bare	Poor Grass	Poor Grass	Poor Grass	Bare	Bare
Recirculation	Yes – 100%	Yes – 100%	Yes – 100%	Yes – 100%	Yes – 100%	Yes – 100%
Liner Defects (Base and Final Cover, If Applicable)	1.0 Pinhole/ Acre, 2 Defects/Acre, "Good" Placement	1.0 Pinhole/ Acre, 2 Defects/Acre, "Good" Placement	1.0 Pinhole/ Acre, 2 Defects/Acre, "Good" Placement	1.0 Pinhole/ Acre, 2 Defects/Acre, "Good" Placement	1.0 Pinhole/ Acre, 2 Defects/Acre, "Good" Placement	1.0 Pinhole/ Acre, 2 Defects/Acre, "Good" Placement
Leaf Index	0	0	0	0	0	0
SCS Runoff Curve Number	84.2	77.5	85.3	86.1	68.7	60.9
Evaporative Zone Depth	24-Inches	24-Inches	18-Inches	18-Inches	24-Inches	24-Inches
Allowable Runoff	0%	0%	100%	100%	100%	100%
Simulation Period	4-Years	20-Years	30-Years	30-Years	30-Years	30-Years

1. Barrier soil (clay) utilized in original prescriptive liner and replaced by caliche in the 2002 Major Permit Amendment. A HELP model demonstration of the effectiveness of the GCL as compared to the barrier soil has been included in this analysis. Modeling for both caliche and GCL alternative liners is provided in Appendix 3J.

Each scenario was evaluated over a simulation period ranging from 4 years to 30 years, as noted in Table 3I-1. Scenarios were modeled to determine the peak daily value for hydraulic head over the liner, liner/cover system efficiency, and leachate generation. Detailed HELP model outputs for each scenario are included in Attachment 1 in Appendix 3I and Peak Daily Hydraulic Head Over Liner values are listed in Table 3I-2.

Table 3I-2
Peak Daily Hydraulic Head Over Base Liner

Scenario[1]	Average Head (inches)	Maximum Head (inches)
Open Condition –Scenario 1 Liner System[1]	2.216	3.677
Open Condition –Scenario 2 Liner System[1]	3.517	5.504
Intermediate Cover Condition	0.406	0.765
Final Cover Condition (Crown)	0.011	0.021
Final Cover Condition (Side Slopes)	0.003	0.008
Final Cover Condition (Crown) – Alternative Cap	0.032	0.032
Final Cover Condition (Side Slopes) – Alternative Cap	0.032	0.064

[1] – Scenario profiles are detailed in Section 3.4.
[2] – All scenarios shown with 100 percent recirculation of leachate collected from the liner.

3I.2.2 Leachate Collection

Leachate Collection System Design

The leachate collection system was designed in accordance with 30 TAC §330.331(a)(2) and §330.333. The leachate collection system and piping must be:

- Designed to maintain less than 30-centimeters (12-inches) of leachate depth over the liner;
- Made of materials that are chemically resistant. The leachate collection system materials shall be constructed of high density poly-ethylene (HDPE);
- Of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, cover materials, and any equipment; and
- Designed and operated to function through the scheduled closure and post-closure care period.

The system design shall consist of the following components:

- Estimated rate of leachate removal from the sump;
- Capacity of the sump;
- Pipe material and strength;
- Pipe network spacing and grading;
- Collection sump materials and strength;

- Drainage media specifications and performance; and,
- Demonstrate that pipes and perforations will be resistant to clogging and can be cleaned.

These design requirements are discussed in further detail in the sections below. Leachate collection system details are provided on Drawing P3-31 in Appendix 3G.

Leachate Collection Layer

30 TAC §330.333(3)(D) and (F)

The leachate collection layer consist of a 24-inch sand protective layer (drainage material) overlying the geomembrane liner. The drainage material will have a minimum coefficient of permeability of 1.0×10^{-3} cm/sec. The effectiveness of this drainage layer is demonstrated in the HELP model analyses completed in Attachment 1 in Appendix 3I. The leachate collection layer will slope at a minimum of one-percent to the leachate collection trench and pipe (maximum of 600-feet).

Existing Sector K sand was also constructed to have a minimum coefficient of permeability of 1.0×10^{-3}cm/sec.

Leachate Aggregate

As outlined in the drawings, the leachate aggregate shall consist of 12-inches of 1 ½-inch washed aggregate and 12-inches of pea-gravel. The aggregate gradation change is implemented to substitute using a geotextile to encase the aggregate, which can be a clogging potential long-term.

The 1 ½-inch washed aggregate backfill shall meet the following specifications:

- Clean, washed, non-carbonate, sub-angular to rounded material, bank run gravel with no organic matter. Crushed aggregate, concrete, bituminous, or limestone not allowed. Soil Classification of GW or GP;
- Meeting the following Gradation (ASTM D422):
  1. 100% passing 1 ½-inch sieve
  2. 0% passing ¾-inch sieve

The pea-gravel backfill shall meet the following specifications:

- Durable washed, non-carbonate, coarse-rounded to sub-angular gravel exhibiting the following relationship to the drainage sand layer:
  1. D15 (Pea-gravel)/D85 (Drainage Sand) < 4 to 5
  2. D15 (Pea-gravel)/D15 (Drainage Sand) < 20
     - Where D_{15} and D_{85} are the diameters which 15% and 85% by weight (respectively) are finer.

Leachate Collection Trenches and Piping

30 TAC §330.333(2) and §330.333(3)(C), (E) and (G)

The leachate collection trenches will slope at a minimum of one-percent to the leachate collection sumps. The leachate collection piping will be placed at the center of the leachate collection trench and will be required to meet the following specifications:

- HDPE pipe designated as PE 3408;
- SDR 9 for perforated leachate collection pipe in trenches (8-inch), cleanout riser pipes (8-inch), and for side-slope riser (SSR) pipes (18-inch);
- Maximum deflection of five percent;
- Pipe perforations for leachate collection piping: ½-inch in diameter, 90-degrees apart symmetrical around the pipe, 5-inch linear spacing (Drawing P3-31 in Appendix 3G); and
- Pipe perforations for sump collection piping: ½-inch in diameter, 45-degrees apart symmetrical around the pipe, 3-inch linear spacing (Drawing P3-32 in Appendix 3G).

Calculations for wall crushing, wall buckling, and ring deflection based on the above design parameters are provided in Attachment 2 in Appendix 3I. Calculations show that the leachate collection systems are of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, waste cover materials, and by any equipment used at the landfill.

Pipe strength calculations were performed separately for the existing lined Phase I/II area (Sector K) to check the pipe strength of the existing pipe in place (6" SDR 11 HDPE pipe). The Sector K pipe calculations are also provided in Appendix 3I, Attachment 2. Calculations show that the existing pipe meets or exceeds the wall crushing, wall buckling and ring deflection requirements for all but the Watkins-Gaube ring deflection. The Watkins-Gaube ring deflection was calculated at 5.15% deflection, which is slightly over the recommended maximum deflection (5%) but under the allowable deflection (7.5%). The pipe is considered to be of sufficient strength and thickness to prevent collapse under the pressures exerted by the additional overlying wastes and waste cover materials for Sector K. Equipment calculations were not provided for Sector K as the critical time for equipment operations over pipe is during the initial lifts of waste being placed in the cell and Sector K already has approximately 50-feet of waste in place to help prevent collapse from equipment.

All leachate piping will have an attached pipe that leads to a reachable point so that the pipe is able to be accessed for cleaning (detail provided on Drawing P3-31 in Appendix 3G).

Geotextile Cushion

Cushion geotextile will be placed between the geomembrane and the leachate collection backfill (and piping) for puncture protection. The geotextile cushion layer shall be a non-woven polypropylene or polyester fabric required to meet the following specifications:

- Fabric Weight: 16 oz per square yard minimum;
- Puncture Resistance: 240 lbs (ASTM D-4833);

Geotextiles will be required to have a sewn seam or an 18-inch minimum sheet overlap.

Leachate Sump and Pump

30 TAC §330.333(3)(A) and (B)

The leachate sump will consist of a 3-foot deep rectangular area. The sump will have a minimum nominal dimension of 8-foot by 8-foot at the base and 26-foot by 26-foot at the top; for a minimum volume of 948 cubic feet (CF). The capacity of the sump has been selected to limit the maximum head on the liner. The media within the sump is to meet the same specifications as that of the 1½-inch aggregate specified for leachate collection aggregate. The average porosity for this aggregate is assumed to be 30%. Based on the porosity, 284 CF (2,124 gallons) in the sump will be available for leachate storage.

Based on the HELP model, the average yearly leachate generation rate for the open condition (maximum leachate generation) is 418 CF/acre/year (or 0.2 gallons per minute (gpm) based on the largest designed sector of 39-acres). Therefore, the recommended pumping size is from 5 gpm to 10 gpm to allow for periodic increases in precipitation.

The pumps will be operated by level transducers to ensure that leachate head does not exceed 12-inches over the liner (or approximately 48-inches in the sump, dependent on actual construction). Transducers will cycle on at approximately 36-inches of head within the sump (or 0-inches of head on the liner) and cycle off at approximately 6-inches of head within the sump. The pump hour reading will be recorded on a quarterly basis and kept in the Site Operating Record.

The leachate sump for Sector K was designed to have a nominal dimension of 7-foot by 7-foot at the base and 21-foot by 21-foot at the top; for a minimum volume of 735 cubic feet (CF). The average porosity for the aggregate is assumed to be 30%. Based on the porosity, 221 CF (1,653 gallons) in the sump are available for leachate storage. Based on the HELP model, the average yearly leachate generation rate for the open condition is 418 CF/acre/year (or 0.1 gpm based on Sector K size of 16.95 acres).

3I.2.3 Leachate Storage

Leachate will be stored within the leachate sump and within the waste mass on site.

3I.2.4 Leachate Disposal

Leachate will be disposed of within the waste mass on site.

3I.2.5 Leachate Recirculation

Leachate removed from the sumps will be recirculated within the waste mass. As shown in the HELP model results in Attachment 1 in Appendix 3I, 100% of the leachate can be recirculated back into the waste mass, while still maintaining less than 12-inches of leachate head on the liner.

The volume of leachate removed and recirculated, based on the sump pump hour meter reading, will be recorded quarterly in the Site Operating Record. Periodic analysis of leachate quality will also be placed in the Site Operating Record.

3I.3 Contaminated Water Management

The Contaminated Water Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) is included in partial form for compliance with 30 TAC §330.305 (b) and (c) Attachment 3 in Appendix 3I. No changes are recommended from this design.

Stormwater that comes into contact with the active working face and is not contained within the site run-on/runoff berms will be managed in the following manner:

- Contaminated water will be contained as best possible within site sedimentation basins or other low-lying areas onsite;
- Testing will be completed on the contaminated water in accordance with the site SWPPP; and
- If testing indicates that the water is contaminated, it will be pumped out of the containment area into a tanker truck and transferred to the El Paso Waste Water Treatment Plant.

Any water that infiltrates or evaporates prior to being transferred offsite shall be considered mitigated or controlled and no further action will be taken.

3I.4 Gas Condensate Management

If gas condensate is produced, it will be stored and disposed of as leachate.

SAIC®

3I.1 Introduction

This Leachate and Contaminated Water Plan has been developed in accordance with 30 TAC §330.65(c), §330.177, §330.207, §330.331(a)(2), and §330.333 for the McCombs Landfill (Landfill) located in El Paso, TX. This plan provides details of the collection, storage, and disposal of contaminated water, leachate, and gas condensate from the leachate collection system, gas monitoring and collection systems, and site operations.

3I.1.1 Definitions

Definitions for the following have been defined by TAC §330.3.

- (36) Contaminated Water – "Leachate, gas condensate, or water that has come into contact with waste."
- (57) Gas Condensate – "The liquid generated as a result of any gas recovery process at a municipal solid waste facility."
- (78) Leachate – "A liquid that has passed through or emerged from solid waste and contains soluble, suspended, or miscible materials removed from such waste."

3I.2 Leachate Management

The Leachate Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) was used to assist in the development of the following section and is provided in partial form as Appendix 3I, Attachment 3. Sections, Figures and Appendices not provided have been updated within.

3I.2.1 Leachate Generation

Leachate generation was estimated by running the Hydrologic Evaluation of Landfill Performance (HELP) Model, Version 3.07. The HELP model is a program that computes the water balance for municipal landfills based on weather, soil, and design data and uses solution techniques that account for the effects of surface storage, runoff, infiltration, evapotranspiration, vegetation, soil moisture storage, subsurface drainage, recirculation, and leakage.

The climate data for the simulations was synthetically generated using coefficients for El Paso, Texas. The various conditions modeled were as follows:

Table 3I-1
HELP Modeling Methodology/Assumptions

Scenario	Open Condition (Daily Cover)	Intermediate Cover Condition	Final Cover Condition (Crown)	Final Cover Condition (Side-Slopes)	Final Cover Condition (Crown) – Alt. Cap	Final Cover Condition (Side-Slopes) – Alt. Cap

1. Barrier soil (clay) utilized in original prescriptive liner and replaced by caliche in the 2002 Major Permit Amendment. A HELP model demonstration of the effectiveness of the GCL as compared to the barrier soil has been included in this analysis. Modeling for both caliche and GCL alternative liners is provided in Appendix 3J.

Each scenario was evaluated over a simulation period ranging from 4 years to 30 years, as noted in Table 3I-1. Scenarios were modeled to determine the peak daily value for hydraulic head over the liner, liner/cover system efficiency, and leachate generation. Detailed HELP model outputs for each scenario are included in Attachment 1 in Appendix 3I and Peak Daily Hydraulic Head Over Liner values are listed in Table 3I-2.

Table 3I-2
Peak Daily Hydraulic Head Over Base Liner

Scenario[1]	Average Head (inches)	Maximum Head (inches)

[1] – Scenario profiles are detailed in Section 3.4.
[2] – All scenarios shown with 100 percent recirculation of leachate collected from the liner.

3I.2.2 Leachate Collection

Leachate Collection System Design

The leachate collection system was designed in accordance with 30 TAC §330.331(a)(2) and §330.333. The leachate collection system and piping must be:

- Designed to maintain less than 30-centimeters (12-inches) of leachate depth over the liner;
- Made of materials that are chemically resistant. The leachate collection system materials shall be constructed of high density poly-ethylene (HDPE);
- Of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, cover materials, and any equipment; and
- Designed and operated to function through the scheduled closure and post-closure care period.

The system design shall consist of the following components:

- Estimated rate of leachate removal from the sump;
- Capacity of the sump;
- Pipe material and strength;
- Pipe network spacing and grading;

- Collection sump materials and strength;
- Drainage media specifications and performance; and,
- Demonstrate that pipes and perforations will be resistant to clogging and can be cleaned.

These design requirements are discussed in further detail in the sections below. Leachate collection system details are provided on Drawing P3-31 in Appendix 3G.

Leachate Collection Layer

30 TAC §330.333(3)(D) and (F)

The leachate collection layer consist of a 24-inch sand protective layer (drainage material) overlying the geomembrane liner. The drainage material will have a minimum coefficient of permeability of 1.0×10^{-3} cm/sec. The effectiveness of this drainage layer is demonstrated in the HELP model analyses completed in Attachment 1 in Appendix 3I. The leachate collection layer will slope at a minimum of one-percent to the leachate collection trench and pipe (maximum of 600-feet).

Existing Sector K sand was also constructed to have a minimum coefficient of permeability of 1.0×10^{-3}cm/sec.

Leachate Aggregate

As outlined in the drawings, the leachate aggregate shall consist of 12-inches of 1 ½-inch washed aggregate and 12-inches of pea-gravel. The aggregate gradation change is implemented to substitute using a geotextile to encase the aggregate, which can be a clogging potential long-term.

The 1 ½-inch washed aggregate backfill shall meet the following specifications:

- Clean, washed, non-carbonate, sub-angular to rounded material, bank run gravel with no organic matter. Crushed aggregate, concrete, bituminous, or limestone not allowed. Soil Classification of GW or GP;
- Meeting the following Gradation (ASTM D422):
  1. 100% passing 1 ½-inch sieve
  2. 0% passing ¾-inch sieve

The pea-gravel backfill shall meet the following specifications:

- Durable washed, non-carbonate, coarse-rounded to sub-angular gravel exhibiting the following relationship to the drainage sand layer:
  1. D15 (Pea-gravel)/D85 (Drainage Sand) < 4 to 5
  2. D15 (Pea-gravel)/D15 (Drainage Sand) < 20
     - Where D_{15} and D_{85} are the diameters which 15% and 85% by weight (respectively) are finer.

Leachate Collection Trenches and Piping

30 TAC §330.333(2) and §330.333(3)(C), (E) and (G)

The leachate collection trenches will slope at a minimum of one-percent to the leachate collection sumps. The leachate collection piping will be placed at the center of the leachate collection trench and will be required to meet the following specifications:

- HDPE pipe designated as PE 3408;
- SDR 9 for perforated leachate collection pipe in trenches (8-inch), cleanout riser pipes (8-inch), and for side-slope riser (SSR) pipes (18-inch);
- Maximum deflection of five percent;
- Pipe perforations for leachate collection piping: ½-inch in diameter, 90-degrees apart symmetrical around the pipe, 5-inch linear spacing (Drawing P3-31 in Appendix 3G); and
- Pipe perforations for sump collection piping: ½-inch in diameter, 45-degrees apart symmetrical around the pipe, 3-inch linear spacing (Drawing P3-32 in Appendix 3G).

Calculations for wall crushing, wall buckling, and ring deflection based on the above design parameters are provided in Attachment 2 in Appendix 3I. Calculations show that the leachate collection systems are of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, waste cover materials, and by any equipment used at the landfill.

Pipe strength calculations were performed separately for the existing lined Phase I/II area (Sector K) to check the pipe strength of the existing pipe in place (6" SDR 11 HDPE pipe). The Sector K pipe calculations are also provided in Appendix 3I, Attachment 2. Calculations show that the existing pipe meets or exceeds the wall crushing, wall buckling and ring deflection requirements for all but the Watkins-Gaube ring deflection. The Watkins-Gaube ring deflection was calculated at 5.15% deflection, which is slightly over the recommended maximum deflection (5%) but under the allowable deflection (7.5%). The pipe is considered to be of sufficient strength and thickness to prevent collapse under the pressures exerted by the additional overlying wastes and waste cover materials for Sector K. Equipment calculations were not provided for Sector K as the critical time for equipment operations over pipe is during the initial lifts of waste being placed in the cell and Sector K already has approximately 50-feet of waste in place to help prevent collapse from equipment.

All leachate piping will have an attached pipe that leads to a reachable point so that the pipe is able to be accessed for cleaning (detail provided on Drawing P3-31 in Appendix 3G).

Geotextile Cushion

Cushion geotextile will be placed between the geomembrane and the leachate collection backfill (and piping) for puncture protection. The geotextile cushion layer shall be a non-woven polypropylene or polyester fabric required to meet the following specifications:

- Fabric Weight: 16 oz per square yard minimum;
- Puncture Resistance: 240 lbs (ASTM D-4833);

Geotextiles will be required to have a sewn seam or an 18-inch minimum sheet overlap.

Leachate Sump and Pump

30 TAC §330.333(3)(A) and (B)

The leachate sump will consist of a 3-foot deep rectangular area. The sump will have a minimum nominal dimension of 8-foot by 8-foot at the base and 26-foot by 26-foot at the top; for a minimum volume of 948 cubic feet (CF). The capacity of the sump has been selected to limit the maximum head on the liner. The media within the sump is to meet the same specifications as that of the 1½-inch aggregate specified for leachate collection aggregate. The average porosity for this aggregate is assumed to be 30%. Based on the porosity, 284 CF (2,124 gallons) in the sump will be available for leachate storage.

Based on the HELP model, the average yearly leachate generation rate for the open condition (maximum leachate generation) is 418 CF/acre/year (or 0.2 gallons per minute (gpm) based on the largest designed sector of 39-acres). Therefore, the recommended pumping size is from 5 gpm to 10 gpm to allow for periodic increases in precipitation.

The pumps will be operated by level transducers to ensure that leachate head does not exceed 12-inches over the liner (or approximately 48-inches in the sump, dependent on actual construction). Transducers will cycle on at approximately 36-inches of head within the sump (or 0-inches of head on the liner) and cycle off at approximately 6-inches of head within the sump. The pump hour reading will be recorded on a quarterly basis and kept in the Site Operating Record.

The leachate sump for Sector K was designed to have a nominal dimension of 7-foot by 7-foot at the base and 21-foot by 21-foot at the top; for a minimum volume of 735 cubic feet (CF). The average porosity for the aggregate is assumed to be 30%. Based on the porosity, 221 CF (1,653 gallons) in the sump are available for leachate storage. Based on the HELP model, the average yearly leachate generation rate for the open condition is 418 CF/acre/year (or 0.1 gpm based on Sector K size of 16.95 acres).

3I.2.3 Leachate Storage

Leachate will be stored within the leachate sump and within the waste mass on site.

3I.2.4 Leachate Disposal

Leachate will be disposed of within the waste mass on site.

3I.2.5 Leachate Recirculation

Leachate removed from the sumps will be recirculated within the waste mass. As shown in the HELP model results in Attachment 1 in Appendix 3I, 100% of the leachate can be recirculated back into the waste mass, while still maintaining less than 12-inches of leachate head on the liner.

The volume of leachate removed and recirculated, based on the sump pump hour meter reading, will be recorded quarterly in the Site Operating Record. Periodic analysis of leachate quality will also be placed in the Site Operating Record.

3I.3 Contaminated Water Management

The Contaminated Water Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) is included in partial form for compliance with 30 TAC §330.305 (b) and (c) Attachment 3 in Appendix 3I. No changes are recommended from this design.

Stormwater that comes into contact with the active working face and is not contained within the site run-on/runoff berms will be managed in the following manner:

- Contaminated water will be contained as best possible within site sedimentation basins or other low-lying areas onsite;
- Testing will be completed on the contaminated water in accordance with the site SWPPP; and
- If testing indicates that the water is contaminated, it will be pumped out of the containment area into a tanker truck and transferred to the El Paso Waste Water Treatment Plant.

Any water that infiltrates or evaporates prior to being transferred offsite shall be considered mitigated or controlled and no further action will be taken.

3I.4 Gas Condensate Management

If gas condensate is produced, it will be stored and disposed of as leachate.

3I.1 Introduction

This Leachate and Contaminated Water Plan has been developed in accordance with 30 TAC §330.65(c), §330.177, §330.207, §330.331(a)(2), and §330.333 for the McCombs Landfill (Landfill) located in El Paso, TX. This plan provides details of the collection, storage, and disposal of contaminated water, leachate, and gas condensate from the leachate collection system, gas monitoring and collection systems, and site operations.

3I.1.1 Definitions

Definitions for the following have been defined by TAC §330.3.

- (36) Contaminated Water – "Leachate, gas condensate, or water that has come into contact with waste."
- (57) Gas Condensate – "The liquid generated as a result of any gas recovery process at a municipal solid waste facility."
- (78) Leachate – "A liquid that has passed through or emerged from solid waste and contains soluble, suspended, or miscible materials removed from such waste"

3I.2 Leachate Management

The Leachate Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) was used to assist in the development of the following section and is provided in partial form as Appendix 3I, Attachment 3. Sections, Figures and Appendices not provided have been updated within.

3I.2.1 Leachate Generation

Leachate generation was estimated by running the Hydrologic Evaluation of Landfill Performance (HELP) Model, Version 3.07. The HELP model is a program that computes the water balance for municipal landfills based on weather, soil, and design data and uses solution techniques that account for the effects of surface storage, runoff, infiltration, evapotranspiration, vegetation, soil moisture storage, subsurface drainage, recirculation, and leakage.

The climate data for the simulations was synthetically generated using coefficients for El Paso, Texas. The various conditions modeled were as follows:

1. Barrier soil (clay) utilized in original prescriptive liner and replaced by caliche in the 2002 Major Permit Amendment. A HELP model demonstration of the effectiveness of the GCL as compared to the barrier soil has been included in this analysis. *Modeling for both caliche and GCL alternative liners is provided in Appendix 3J.*

Each scenario was evaluated over a simulation period ranging from 4 years to 30 years, as noted in Table 3I-1. Scenarios were modeled to determine the peak daily value for hydraulic head over the liner, liner/cover system efficiency, and leachate generation. Detailed HELP model outputs for each scenario are included in Attachment 1 in Appendix 3I and Peak Daily Hydraulic Head Over Liner values are listed in Table 3I-2.

Table 3I-2
Peak Daily Hydraulic Head Over Base Liner

Scenario[1]	Average Head (inches)	Maximum Head (inches)
Open Condition – Prescriptive Liner with Barrier Soil	2.216	3.677
Open Condition – Alternative Liner with GCL	3.594	5.607
Intermediate Cover Condition	0.407	0.765
Final Cover Condition (Crown)	0.011	0.021
Final Cover Condition (Side Slopes)	0.003	0.007
Final Cover Condition (Crown) – Alternative Cap	0.016	0.031
Final Cover Condition (Side Slopes) – Alternative Cap	0.032	0.064

1. All scenarios shown with 100 percent recirculation of leachate collected from the liner.

3I.2.2 Leachate Collection

Leachate Collection System Design

The leachate collection system was designed in accordance with 30 TAC §330.331(a)(2) and §330.333. The leachate collection system and piping must be:

- Designed to maintain less than 30-centimeters (12-inches) of leachate depth over the liner;
- Made of materials that are chemically resistant. The leachate collection system materials shall be constructed of high density poly-ethylene (HDPE);
- Of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, cover materials, and any equipment; and
- Designed and operated to function through the scheduled closure and post-closure care period.

The system design shall consist of the following components:

- Estimated rate of leachate removal from the sump;
- Capacity of the sump;
- Pipe material and strength;
- Pipe network spacing and grading;
- Collection sump materials and strength;

- Drainage media specifications and performance; and,
- Demonstrate that pipes and perforations will be resistant to clogging and can be cleaned.

These design requirements are discussed in further detail in the sections below. Leachate collection system details are provided on Drawing P3-31 in Appendix 3G.

Leachate Collection Layer

30 TAC §330.333(3)(D) and (F)

The leachate collection layer consist of ~~2 feet of~~ ***a 24-inch sand protective layer (***drainage material***)*** overlying the geomembrane liner. The drainage material will have a minimum coefficient of permeability of 1.0×10^{-3} cm/sec. The effectiveness of this drainage layer is demonstrated in the HELP model analyses completed in Attachment 1 in Appendix 3I. The leachate collection layer will slope at a minimum of one-percent to the leachate collection trench and pipe (maximum of 600-feet).

Existing Sector K sand was also constructed to have a minimum coefficient of permeability of 1.0×10^{-3}cm/sec.

Leachate Aggregate

As outlined in the drawings, the leachate aggregate shall consist of 12-inches of 1 ½-inch washed aggregate and 12-inches of pea-gravel. The aggregate gradation change is implemented to substitute using a geotextile to encase the aggregate, which can be a clogging potential long-term.

The 1 ½-inch washed aggregate backfill shall meet the following specifications:

- Clean, washed, non-carbonate, sub-angular to rounded material, bank run gravel with no organic matter. Crushed aggregate, concrete, bituminous, or limestone not allowed. Soil Classification of GW or GP;
- Meeting the following Gradation (ASTM D422):
  1. 100% passing 1 ½-inch sieve
  2. 0% passing ¾-inch sieve

The pea-gravel backfill shall meet the following specifications:

- Durable washed, non-carbonate, coarse-rounded to sub-angular gravel exhibiting the following relationship to the drainage sand layer:
  1. D15 (Pea-gravel)/D85 (Drainage Sand) < 4 to 5
  2. D15 (Pea-gravel)/D15 (Drainage Sand) < 20
     - Where D_{15} and D_{85} are the diameters which 15% and 85% by weight (respectively) are finer.

Leachate Collection Trenches and Piping

30 TAC §330.333(2) and §330.333(3)(C), (E) and (G)

The leachate collection trenches will slope at a minimum of one-percent to the leachate collection sumps. The leachate collection piping will be placed at the center of the leachate collection trench and will be required to meet the following specifications:

- HDPE pipe designated as PE 3408;
- SDR 9 for perforated leachate collection pipe in trenches (8-inch), cleanout riser pipes (8-inch), and for side-slope riser (SSR) pipes (18-inch);
- Maximum deflection of five percent;
- Pipe perforations for leachate collection piping: ½-inch in diameter, 90-degrees apart symmetrical around the pipe, 5-inch linear spacing (Drawing P3-31 in Appendix 3G); and
- Pipe perforations for sump collection piping: ½-inch in diameter, 45-degrees apart symmetrical around the pipe, 3-inch linear spacing (Drawing P3-32 in Appendix 3G).

Calculations for wall crushing, wall buckling, and ring deflection based on the above design parameters are provided in Attachment 2 in Appendix 3I. Calculations show that the ~~proposed~~ leachate collection systems are of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, waste cover materials, and by any equipment used at the landfill.

Pipe strength calculations were performed separately for the existing lined Phase I/II area (Sector K) to check the pipe strength of the existing pipe in place (6" SDR 11 HDPE pipe). The Sector K pipe calculations are also provided in Appendix 3I, Attachment 2. Calculations show that the existing pipe meets or exceeds the wall crushing, wall buckling and ring deflection requirements for all but the Watkins-Gaube ring deflection. The Watkins-Gaube ring deflection was calculated at 5.15% deflection, which is slightly over the recommended maximum deflection (5%) but under the allowable deflection (7.5%). The pipe is considered to be of sufficient strength and thickness to prevent collapse under the pressures exerted by the additional overlying wastes and waste cover materials for Sector K. Equipment calculations were not provided for Sector K as the critical time for equipment operations over pipe is during the initial lifts of waste being placed in the cell and Sector K already has approximately 50-feet of waste in place to help prevent collapse from equipment.

All leachate piping will have an attached pipe that leads to a reachable point so that the pipe is able to be accessed for cleaning (detail provided on Drawing P3-31 in Appendix 3G).

Geotextile Cushion

Cushion geotextile will be placed between the geomembrane and the leachate collection backfill (and piping) for puncture protection. The geotextile cushion layer shall be a non-woven polypropylene or polyester fabric required to meet the following specifications:

- Fabric Weight: 16 oz per square yard minimum;
- Puncture Resistance: 240 lbs (ASTM D-4833);

Geotextiles will be required to have a sewn seam or an 18-inch minimum sheet overlap.

Leachate Sump and Pump

30 TAC §330.333(3)(A) and (B)

The leachate sump will consist of a 3-foot deep rectangular area. The sump will have a minimum nominal dimension of 8-foot by 8-foot at the base and 26-foot by 26-foot at the top; for a minimum volume of 948 cubic feet (CF). The capacity of the sump has been selected to limit the maximum head on the liner. The media within the sump is to meet the same specifications as that of the 1½-inch aggregate specified for leachate collection aggregate. The average porosity for this aggregate is assumed to be 30%. Based on the porosity, 284 CF (2,124 gallons) in the sump will be available for leachate storage.

Based on the HELP model, the average yearly leachate generation rate for the open condition (maximum leachate generation) is 418 CF/acre/year (or 0.2 gallons per minute (gpm) based on the largest designed sector of 39-acres). Therefore, the recommended pumping size is from 5 gpm to 10 gpm to allow for periodic increases in precipitation.

The pumps will be operated by level transducers to ensure that leachate head does not exceed 12-inches over the liner (or approximately 48-inches in the sump, dependent on actual construction). Transducers will cycle on at approximately 36-inches of head within the sump (or 0-inches of head on the liner) and cycle off at approximately 6-inches of head within the sump. The pump hour reading will be recorded on a quarterly basis and kept in the Site Operating Record.

The leachate sump for Sector K was designed to have a nominal dimension of 7-foot by 7-foot at the base and 21-foot by 21-foot at the top; for a minimum volume of 735 cubic feet (CF). The average porosity for the aggregate is assumed to be 30%. Based on the porosity, 221 CF (1,653 gallons) in the sump are available for leachate storage. Based on the HELP model, the average yearly leachate generation rate for the open condition is 418 CF/acre/year (or 0.1 gpm based on Sector K size of 16.95 acres).

3I.2.3 Leachate Storage

Leachate will be stored within the leachate sump and within the waste mass on site.

3I.2.4 Leachate Disposal

Leachate will be disposed of within the waste mass on site.

3I.2.5 Leachate Recirculation

Leachate removed from the sumps will be recirculated within the waste mass. As shown in the HELP model results in Attachment 1 in Appendix 3I, 100% of the leachate can be recirculated back into the waste mass, while still maintaining less than 12-inches of leachate head on the liner.

The volume of leachate removed and recirculated, based on the sump pump hour meter reading, will be recorded quarterly in the Site Operating Record. Periodic analysis of leachate quality will also be placed in the Site Operating Record.

3I.3 Contaminated Water Management

The Contaminated Water Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) is included in partial form for compliance with 30 TAC §330.305 (b) and (c) Attachment 3 in Appendix 3I. No changes are recommended from this design.

Stormwater that comes into contact with the active working face and is not contained within the site run-on/runoff berms will be managed in the following manner:

- Contaminated water will be contained as best possible within site sedimentation basins or other low-lying areas onsite;
- Testing will be completed on the contaminated water in accordance with the site SWPPP; and
- If testing indicates that the water is contaminated, it will be pumped out of the containment area into a tanker truck and transferred to the El Paso Waste Water Treatment Plant.

Any water that infiltrates or evaporates prior to being transferred offsite shall be considered mitigated or controlled and no further action will be taken.

3I.4 Gas Condensate Management

If gas condensate is produced, it will be stored and disposed of as leachate.

3I.1 Introduction

This Leachate and Contaminated Water Plan has been developed in accordance with 30 TAC §330.65(c), §330.177, §330.207, §330.331(a)(2), and §330.333 for the McCombs Landfill (Landfill) located in El Paso, TX. This plan provides details of the collection, storage, and disposal of contaminated water, leachate, and gas condensate from the leachate collection system, gas monitoring and collection systems, and site operations.

3I.1.1 Definitions

Definitions for the following have been defined by TAC §330.3.

- (36) Contaminated Water – "Leachate, gas condensate, or water that has come into contact with waste."
- (57) Gas Condensate – "The liquid generated as a result of any gas recovery process at a municipal solid waste facility."
- (78) Leachate – "A liquid that has passed through or emerged from solid waste and contains soluble, suspended, or miscible materials removed from such waste"

3I.2 Leachate Management

The Leachate Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) was used to assist in the development of the following section ***and is provided in partial form as Appendix 3I, Attachment 3. Sections, Figures and Appendices not provided have been updated within***.

3I.2.1 Leachate Generation

Leachate generation was estimated by running the Hydrologic Evaluation of Landfill Performance (HELP) Model, Version 3.07. The HELP model is a program that computes the water balance for municipal landfills based on weather, soil, and design data and uses solution techniques that account for the effects of surface storage, runoff, infiltration, evapotranspiration, vegetation, soil moisture storage, subsurface drainage, recirculation, and leakage.

The climate data for the simulations was synthetically generated using coefficients for El Paso, Texas. The various conditions modeled were as follows:

Table 3I-1

1. All scenarios shown with 100 percent recirculation of leachate collected from the liner.

3I.2.2 Leachate Collection

Leachate Collection System Design

The leachate collection system was designed in accordance with 30 TAC §330.331(a)(2) and §330.333. The leachate collection system and piping must be:

- Designed to maintain ~~a minimum of~~ ***less than*** 30-centimeters (12-inches) of leachate depth over the liner;
- Made of materials that are chemically resistant. The leachate collection system materials shall be constructed of high density poly-ethylene (HDPE);
- Of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, cover materials, and any equipment; and
- Designed and operated to function through the scheduled closure and post-closure care period.

The system design shall consist of the following components:

- Estimated rate of leachate removal from the sump;
- Capacity of the sump;
- Pipe material and strength;
- Pipe network spacing and grading;
- Collection sump materials and strength;
- Drainage media specifications and performance; and,

- Demonstrate that pipes and perforations will be resistant to clogging and can be cleaned.

These design requirements are discussed in further detail in the sections below. Leachate collection system details are provided on Drawing P3-31 in Appendix 3G.

Leachate Collection Layer

30 TAC §330.333(3)(D) and (F)

The leachate collection layer consist of 2-feet of drainage material overlying the geomembrane liner. The drainage material will have a minimum coefficient of permeability of 1.0 x 10^{-3} cm/sec. The effectiveness of this drainage layer is demonstrated in the HELP model analyses completed in Attachment 1 in Appendix 3I. The leachate collection layer will slope at a minimum of one-percent to the leachate collection trench and pipe (maximum of 600-feet).

Existing Sector K sand was also constructed to have a minimum coefficient of permeability of 1.0 x 10^{-3} cm/sec.

Leachate Aggregate

As outlined in the drawings, the leachate aggregate shall consist of 12-inches of 1 ½-inch washed aggregate and 12-inches of pea-gravel. The aggregate gradation change is implemented to substitute using a geotextile to encase the aggregate, which can be a clogging potential long-term.

The 1 ½-inch washed aggregate backfill shall meet the following specifications:

- Clean, washed, non-carbonate, sub-angular to rounded material, bank run gravel with no organic matter. Crushed aggregate, concrete, bituminous, or limestone not allowed. Soil Classification of GW or GP;
- Meeting the following Gradation (ASTM D422):
  1. 100% passing 1 ½-inch sieve
  2. 0% passing ¾-inch sieve

The pea-gravel backfill shall meet the following specifications:

- Durable washed, non-carbonate, coarse-rounded to sub-angular gravel exhibiting the following relationship to the drainage sand layer:
  1. D15 (Pea-gravel)/D85 (Drainage Sand) < 4 to 5
  2. D15 (Pea-gravel)/D15 (Drainage Sand) < 20
     - Where D_{15} and D_{85} are the diameters which 15% and 85% by weight (respectively) are finer.

Leachate Collection Trenches and Piping

30 TAC §330.333(2) and §330.333(3)(C), (E) and (G)

The leachate collection trenches will slope at a minimum of one-percent to the leachate collection sumps. The leachate collection piping will be placed at the center of the leachate collection trench and will be required to meet the following specifications:

- HDPE pipe designated as PE 3408;
- SDR 9 for perforated leachate collection pipe in trenches (8-inch), cleanout riser pipes (8-inch), and for side-slope riser (SSR) pipes (18-inch);
- Maximum deflection of five percent;
- Pipe perforations for leachate collection piping: ½-inch in diameter, 90-degrees apart symmetrical around the pipe, 5-inch linear spacing (Drawing P3-31 in Appendix 3G); and
- Pipe perforations for sump collection piping: ½-inch in diameter, 45-degrees apart symmetrical around the pipe, 3-inch linear spacing (Drawing P3-32 in Appendix 3G).

Calculations for wall crushing, wall buckling, and ring deflection based on the above design parameters are provided in Attachment 2 in Appendix 3I. ***Calculations show that the proposed leachate collection systems are of sufficient strength and thickness to prevent collapse under the pressures exerted by overlying wastes, waste cover materials, and by any equipment used at the landfill.***

Pipe strength calculations were performed separately for the existing lined Phase I/II area (Sector K) to check the pipe strength of the existing pipe in place (6" SDR 11 HDPE pipe). The Sector K pipe calculations are also provided in Appendix 3I, Attachment 2. Calculations show that the existing pipe meets or exceeds the wall crushing, wall buckling and ring deflection requirements for all but the Watkins-Gaube ring deflection. The Watkins-Gaube ring deflection was calculated at 5.15% deflection, which is slightly over the recommended maximum deflection (5%) but under the allowable deflection (7.5%). The pipe is considered to be of sufficient strength and thickness to prevent collapse under the pressures exerted by the additional overlying wastes and waste cover materials for Sector K. Equipment calculations were not provided for Sector K as the critical time for equipment operations over pipe is during the initial lifts of waste being placed in the cell and Sector K already has approximately 50-feet of waste in place to help prevent collapse from equipment.

All leachate piping will have an attached pipe that leads to a reachable point so that the pipe is able to be accessed for cleaning (detail provided on Drawing P3-31 in Appendix 3G).

Geotextile Cushion

Cushion geotextile will be placed between the geomembrane and the leachate collection backfill (and piping) for puncture protection. The geotextile cushion layer shall be a non-woven polypropylene or polyester fabric required to meet the following specifications:

- Fabric Weight: 16 oz per square yard minimum;
- Puncture Resistance: 240 lbs (ASTM D-4833);

Geotextiles will be required to have a sewn seam or an 18-inch minimum sheet overlap.

Leachate Sump and Pump

30 TAC §330.333(3)(A) and (B)

The leachate sump will consist of a 3-foot deep rectangular area. The sump will have a minimum nominal dimension of 8-foot by 8-foot at the base and 26-foot by 26-foot at the top; for a minimum volume of 948 cubic feet (CF). The capacity of the sump has been selected to limit the maximum head on the liner. The media within the sump is to meet the same specifications as that of the 1½-inch aggregate specified for leachate collection aggregate. The average porosity for this aggregate is assumed to be 30%. Based on the porosity, 284 CF (2,124 gallons) in the sump will be available for leachate storage.

Based on the HELP model, the average yearly leachate generation rate for the open condition (maximum leachate generation) is ***418*** ~~1,593~~ CF/acre/year (or ***0.2*** ~~1.0~~ gallons per minute (gpm) based on the largest designed sector of 39-acres). Therefore, the recommended pumping size is from 5 gpm to 10 gpm to allow for periodic increases in precipitation.

The pumps will be operated by level transducers to ensure that leachate head does not exceed 12-inches over the liner (or approximately 48-inches in the sump, dependent on actual construction). Transducers will cycle on at approximately 36-inches of head within the sump (or 0-inches of head on the liner) and cycle off at approximately 6-inches of head within the sump. The pump hour reading will be recorded on a quarterly basis and kept in the Site Operating Record.

The leachate sump for Sector K was designed to have a nominal dimension of 7-foot by 7-foot at the base and 21-foot by 21-foot at the top; for a minimum volume of 735 cubic feet (CF). The average porosity for the aggregate is assumed to be 30%. Based on the porosity, 221 CF (1,653 gallons) in the sump are available for leachate storage. Based on the HELP model, the average yearly leachate generation rate for the open condition is 418 CF/acre/year (or 0.1 gpm based on Sector K size of 16.95 acres).

3I.2.3 Leachate Storage

Leachate will be stored within the leachate sump and within the waste mass on site.

3I.2.4 Leachate Disposal

Leachate will be disposed of within the waste mass on site.

3I.2.5 Leachate Recirculation

Leachate removed from the sumps will be recirculated within the waste mass. As shown in the HELP model results in Attachment 1 in Appendix 3I, 100% of the leachate can be recirculated back into the waste mass, while still maintaining less than 12-inches of leachate head on the liner.

The volume of leachate removed and recirculated, based on the sump pump hour meter reading, will be recorded ***quarterly*** ~~monthly~~ in the Site Operating Record. Periodic analysis of leachate quality will also be placed in the Site Operating Record.

3I.3 Contaminated Water Management

The Contaminated Water Management Plan developed by Raba-Kistner Consultants, Inc., dated April 24, 2002 (Revision 1 – July 29, 2002) is included in ***partial form for compliance with 30 TAC §330.305 (b) and (c)*** Attachment 3 in Appendix 3I. No changes are recommended from this design.

Stormwater that comes into contact with the active working face and is not contained within the site run-on/runoff berms will be managed in the following manner:

- ***Contaminated water will be contained as best possible within site sedimentation basins or other low-lying areas onsite;***
- ***Testing will be completed on the contaminated water in accordance with the site SWPPP; and***
- ***If testing indicates that the water is contaminated, it will be pumped out of the containment area into a tanker truck and transferred to the El Paso Waste Water Treatment Plant.***

Any water that infiltrates or evaporates prior to being transferred offsite shall be considered mitigated or controlled and no further action will be taken.

3I.4 Gas Condensate Management

If gas condensate is produced, it will be stored and disposed of as leachate.

GENERAL DESIGN AND EVAPORATIVE ZONE DATA

NOTE: SCS RUNOFF CURVE NUMBER WAS COMPUTED FROM DEFAULT SOIL DATA BASE USING SOIL TEXTURE # 8 WITH A POOR STAND OF GRASS, A SURFACE SLOPE OF 7.% AND A SLOPE LENGTH OF 1019. FEET.

SCS RUNOFF CURVE NUMBER	=	85.30	
FRACTION OF AREA ALLOWING RUNOFF	=	100.0	PERCENT
AREA PROJECTED ON HORIZONTAL PLANE	=	1.000	ACRES
EVAPORATIVE ZONE DEPTH	=	18.0	INCHES
INITIAL WATER IN EVAPORATIVE ZONE	=	2.369	INCHES

UPPER LIMIT OF EVAPORATIVE STORAGE	=	8.022	INCHES
LOWER LIMIT OF EVAPORATIVE STORAGE	=	0.984	INCHES
INITIAL SNOW WATER	=	0.000	INCHES
INITIAL WATER IN LAYER MATERIALS	=	816.995	INCHES
TOTAL INITIAL WATER	=	816.995	INCHES
TOTAL SUBSURFACE INFLOW	=	0.00	INCHES/YEAR

EVAPOTRANSPIRATION AND WEATHER DATA

NOTE: EVAPOTRANSPIRATION DATA WAS OBTAINED FROM
EL PASO TEXAS

STATION LATITUDE	=	31.80	DEGREES
MAXIMUM LEAF AREA INDEX	=	0.00	
START OF GROWING SEASON (JULIAN DATE)	=	66	
END OF GROWING SEASON (JULIAN DATE)	=	315	
EVAPORATIVE ZONE DEPTH	=	18.0	INCHES
AVERAGE ANNUAL WIND SPEED	=	9.20	MPH
AVERAGE 1ST QUARTER RELATIVE HUMIDITY	=	40.00	%
AVERAGE 2ND QUARTER RELATIVE HUMIDITY	=	27.00	%
AVERAGE 3RD QUARTER RELATIVE HUMIDITY	=	46.00	%
AVERAGE 4TH QUARTER RELATIVE HUMIDITY	=	48.00	%

NOTE: PRECIPITATION DATA WAS SYNTHETICALLY GENERATED USING
COEFFICIENTS FOR EL PASO TEXAS

NORMAL MEAN MONTHLY PRECIPITATION (INCHES)

JAN/JUL	FEB/AUG	MAR/SEP	APR/OCT	MAY/NOV	JUN/DEC
0.38	0.45	0.32	0.19	0.24	0.56
1.60	1.21	1.42	0.73	0.33	0.39

NOTE: TEMPERATURE DATA WAS SYNTHETICALLY GENERATED USING
COEFFICIENTS FOR EL PASO TEXAS

NORMAL MEAN MONTHLY TEMPERATURE (DEGREES FAHRENHEIT)

JAN/JUL	FEB/AUG	MAR/SEP	APR/OCT	MAY/NOV	JUN/DEC
44.20	48.40	55.10	63.60	71.90	80.80
82.50	80.30	74.10	63.60	51.40	44.40

NOTE: SOLAR RADIATION DATA WAS SYNTHETICALLY GENERATED USING
COEFFICIENTS FOR EL PASO TEXAS
AND STATION LATITUDE = 31.80 DEGREES

TITLE: CLOSED CONDITIONS - PRESCRIBED FINAL COVER (SIDESLOPES)

****

NOTE: INITIAL MOISTURE CONTENT OF THE LAYERS AND SNOW WATER
WERE SPECIFIED BY THE USER.

LAYER 1

TYPE 1 - VERTICAL PERCOLATION LAYER
MATERIAL TEXTURE NUMBER 8

THICKNESS	=	6.00	INCHES
POROSITY	=	0.4630	VOL/VOL
FIELD CAPACITY	=	0.2320	VOL/VOL
WILTING POINT	=	0.1160	VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.2638	VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.369999994000E-03	CM/SEC

LAYER 2

TYPE 2 - LATERAL DRAINAGE LAYER

MATERIAL TEXTURE NUMBER 2

THICKNESS	=	12.00	INCHES
POROSITY	=	0.4370	VOL/VOL
FIELD CAPACITY	=	0.0620	VOL/VOL
WILTING POINT	=	0.0240	VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.0400	VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.579999993000E-02	CM/SEC
SLOPE	=	33.00	PERCENT
DRAINAGE LENGTH	=	475.0	FEET

LAYER 3

TYPE 4 - FLEXIBLE MEMBRANE LINER

MATERIAL TEXTURE NUMBER 36

THICKNESS	=	0.04	INCHES
POROSITY	=	0.0000	VOL/VOL
FIELD CAPACITY	=	0.0000	VOL/VOL
WILTING POINT	=	0.0000	VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.0000	VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.399999993000E-12	CM/SEC
FML PINHOLE DENSITY	=	1.00	HOLES/ACRE
FML INSTALLATION DEFECTS	=	2.00	HOLES/ACRE
FML PLACEMENT QUALITY	=	3 - GOOD	

LAYER 4

TYPE 3 - BARRIER SOIL LINER

MATERIAL TEXTURE NUMBER 0

THICKNESS	=	18.00	INCHES
POROSITY	=	0.4570	VOL/VOL
FIELD CAPACITY	=	0.1310	VOL/VOL
WILTING POINT	=	0.0580	VOL/VOL

EFFECTIVE SAT. HYD. COND.	=	0.100000005000E-02 CM/SEC

LAYER 8

TYPE 1 - VERTICAL PERCOLATION LAYER
MATERIAL TEXTURE NUMBER 0

THICKNESS	=	12.00 INCHES
POROSITY	=	0.4370 VOL/VOL
FIELD CAPACITY	=	0.0620 VOL/VOL
WILTING POINT	=	0.0240 VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.0621 VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.100000005000E-02 CM/SEC

LAYER 9

TYPE 2 - LATERAL DRAINAGE LAYER
MATERIAL TEXTURE NUMBER 0

THICKNESS	=	12.00 INCHES
POROSITY	=	0.4370 VOL/VOL
FIELD CAPACITY	=	0.0620 VOL/VOL
WILTING POINT	=	0.0240 VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.0620 VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.100000005000E-02 CM/SEC
SLOPE	=	1.00 PERCENT
DRAINAGE LENGTH	=	350.0 FEET

NOTE: 100.00 PERCENT OF THE DRAINAGE COLLECTED FROM THIS LAYER IS RECIRCULATED INTO LAYER # 6.

LAYER 10

TYPE 4 - FLEXIBLE MEMBRANE LINER
MATERIAL TEXTURE NUMBER 35

THICKNESS	=	0.06 INCHES
POROSITY	=	0.0000 VOL/VOL
FIELD CAPACITY	=	0.0000 VOL/VOL
WILTING POINT	=	0.0000 VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.0000 VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.199999996000E-12 CM/SEC
FML PINHOLE DENSITY	=	1.00 HOLES/ACRE
FML INSTALLATION DEFECTS	=	2.00 HOLES/ACRE
FML PLACEMENT QUALITY	=	3 - GOOD

LAYER 11

TYPE 3 - BARRIER SOIL LINER
MATERIAL TEXTURE NUMBER 0

THICKNESS	=	0.24 INCHES
POROSITY	=	0.7500 VOL/VOL
FIELD CAPACITY	=	0.7470 VOL/VOL
WILTING POINT	=	0.4000 VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.7500 VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.499999997000E-08 CM/SEC

LAYER 12

TYPE 1 - VERTICAL PERCOLATION LAYER
MATERIAL TEXTURE NUMBER 2

THICKNESS	=	6.00 INCHES
POROSITY	=	0.4370 VOL/VOL
FIELD CAPACITY	=	0.0620 VOL/VOL
WILTING POINT	=	0.0240 VOL/VOL
INITIAL SOIL WATER CONTENT	=	0.0610 VOL/VOL
EFFECTIVE SAT. HYD. COND.	=	0.579999993000E-02 CM/SEC

GENERAL DESIGN AND EVAPORATIVE ZONE DATA

NOTE: SCS RUNOFF CURVE NUMBER WAS COMPUTED FROM DEFAULT SOIL DATA BASE USING SOIL TEXTURE # 8 WITH A POOR STAND OF GRASS, A SURFACE SLOPE OF 33.% AND A SLOPE LENGTH OF 759. FEET.

SCS RUNOFF CURVE NUMBER	=	86.10	
FRACTION OF AREA ALLOWING RUNOFF	=	100.0	PERCENT
AREA PROJECTED ON HORIZONTAL PLANE	=	1.000	ACRES
EVAPORATIVE ZONE DEPTH	=	18.0	INCHES
INITIAL WATER IN EVAPORATIVE ZONE	=	2.063	INCHES

UPPER LIMIT OF EVAPORATIVE STORAGE	=	8.022	INCHES
LOWER LIMIT OF EVAPORATIVE STORAGE	=	0.984	INCHES
INITIAL SNOW WATER	=	0.000	INCHES
INITIAL WATER IN LAYER MATERIALS	=	663.660	INCHES
TOTAL INITIAL WATER	=	663.660	INCHES
TOTAL SUBSURFACE INFLOW	=	0.00	INCHES/YEAR

EVAPOTRANSPIRATION AND WEATHER DATA

NOTE: EVAPOTRANSPIRATION DATA WAS OBTAINED FROM
EL PASO TEXAS

STATION LATITUDE	=	31.80	DEGREES
MAXIMUM LEAF AREA INDEX	=	0.00	
START OF GROWING SEASON (JULIAN DATE)	=	66	
END OF GROWING SEASON (JULIAN DATE)	=	315	
EVAPORATIVE ZONE DEPTH	=	18.0	INCHES
AVERAGE ANNUAL WIND SPEED	=	9.20	MPH
AVERAGE 1ST QUARTER RELATIVE HUMIDITY	=	40.00	%
AVERAGE 2ND QUARTER RELATIVE HUMIDITY	=	27.00	%
AVERAGE 3RD QUARTER RELATIVE HUMIDITY	=	46.00	%
AVERAGE 4TH QUARTER RELATIVE HUMIDITY	=	48.00	%

NOTE: PRECIPITATION DATA WAS SYNTHETICALLY GENERATED USING
COEFFICIENTS FOR EL PASO TEXAS

NORMAL MEAN MONTHLY PRECIPITATION (INCHES)

JAN/JUL	FEB/AUG	MAR/SEP	APR/OCT	MAY/NOV	JUN/DEC
0.38	0.45	0.32	0.19	0.24	0.56
1.60	1.21	1.42	0.73	0.33	0.39

NOTE: TEMPERATURE DATA WAS SYNTHETICALLY GENERATED USING
COEFFICIENTS FOR EL PASO TEXAS

NORMAL MEAN MONTHLY TEMPERATURE (DEGREES FAHRENHEIT)

JAN/JUL	FEB/AUG	MAR/SEP	APR/OCT	MAY/NOV	JUN/DEC
44.20	48.40	55.10	63.60	71.90	80.80
82.50	80.30	74.10	63.60	51.40	44.40

NOTE: SOLAR RADIATION DATA WAS SYNTHETICALLY GENERATED USING
COEFFICIENTS FOR EL PASO TEXAS
AND STATION LATITUDE = 31.80 DEGREES

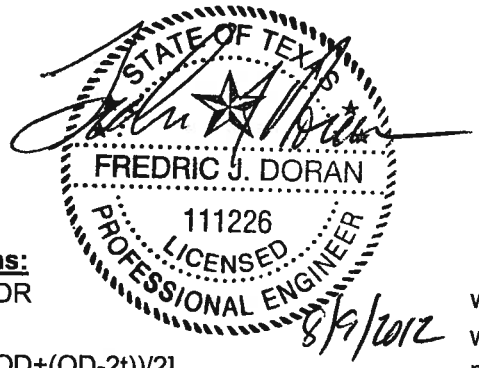
Appendix 3I - Attachment 2
Pipe Deflection Calculations

SAIC®

Pipe Deflection Calculations
McCombs Landfill - 4/15/11 (SSK)



6 inch pipe

Equations:

t = OD/SDR — wall thickness
$I = t^3/12$ — wall moment of inertia
R = 0.5[(OD+(OD-2t))/2] — mean radius
W = OD*[(6*120)+(120*66.7)]/144 — vertical stress
Wp = (W*12)/(12-(D_p*N)) — modified vertical stress
$x = (D*K*W*R^3) / [(E*I) + (0.061*E'*R^3)]$ — deflection
Deflection % = x/(2*R)

Input Variables

OD (in.) =	6.625	
K =	0.1	pipe bedding constant (0.1)
D =	1.0	deflection lag factor (1.0)
E (psi) =	133,000	Pipe Mod of Elasticity
E' (psi) =	3,000	Soil Mod of Reaction
Soil Cover Depth (ft.) =	8	
Waste Depth (ft.) =	264	
Soil Cover Dens. (pcf) =	120	
Waste Dens. (pcf) =	66.7	
D_p =	0.5	diameter of perforation (inches)
N =	2.4	number of perforations per foot

Design Criteria

Recommended Maximum Deflection	5.0%
Allowable Maximum Deflection	7.5%

Deflection Calculations

11/2/12

Pipe Design by Compressive Ring Thrust Stress and Ring Deflection
McCombs Landfill - 4/15/11 (SSK)

Compressive Ring Thrust Stress of 6" diameter perforated HDPE leachate collection pipe.

SDR = 9 Design Value

$$VAF = 0.88 - 0.71 * \frac{S_a - 1}{S_a + 2.5}$$

VAF = Vertical Arching Factor

S_a = Hoop Thrust Stiffness Ratio

$$S_a = \frac{1.43 * M_s * r_{CENT}}{EA}$$

r_{CENT} = radius to centroidal axis of pipe, in

M_s = one-dimensional modulus of soil, psi

E = apparent modulus of elasticity of pipe material, psi

A = profile wall average cross-sectional area, in2/in, or wall thickness (in) for DR pipe

Calculate Vertical Soil Stress = (depth * density)/144

Waste Depth (ft.) W_d =	264	ft	Design Value
Waste Dens. (pcf) =	66.7	pcf	Standard Parameter
Vertical Soil Stress =	122.283	psi	Calculated

Use Table 2-14 in PPI PE Handbook, Chapter 6, Page 226 to determine M_s

M_s =	3534.5	psi	(assuming a 90% compaction.)
r_{CENT} =	3.3125	in	
E =	28,250	psi	Standard Value for HDPE pipe, 50 year life (Table 2-6, Chapter 6, PE Handbook, p209)
A =	0.736	in	Minimum Wall thickness for SDR 9 pipe (Forrer Supply)
S_a =	**0.805**		Stiffness, Calculated
VAF =	**0.922**		Arching Factor, Calculated

Soil Cover Depth (ft.) S_d =	8	Design Value
Waste Depth (ft.) W_d =	264	Design Value
Soil Cover Dens. (pcf) =	120	Standard Parameter
Waste Dens. (pcf) =	66.7	Standard Parameter

$$P_{rd} = VAF * [(S_d * S_{Density}) + (W_d + W_{Density})]$$

P_{rd} =	17117.4105	psf	Radial Directed Eart Pressure, Calculated
P_{rd} =	**118.87**	**psi**	Radial Directed Eart Pressure, Calculated

$$S = \frac{P_{rd} * D_o}{288 * A}$$

S =	**535.00**	**psi**	Ring Compressive Stress, Calculated
	<		
	1000	psi	Max Compressive Yield Strength for PE 3408 HDPE pipe (Handbook of Polyethylene Pipe, Appendix 3, pg 102)

OK

Ring Deflection of Pipes Using Watkins-Gaube Graph

$$R_f = \frac{12 * E_s (SDR - 1)^3}{E}$$

$$E_s = M_S * \frac{(1+\mu)(1-2\mu)}{(1-\mu)}$$

SDR =	9		Design Factor
E_s =	2625.62857	psi	Secant modulus of the soil, Calculated
E =	28,250	psi	Standard Value for HDPE pipe, 50 year life (Table 2-6, Chapter 6, PE Handbook, p209)
D_m =	5.89	in	Mean Diameter (D_o -t), Calculated
D_o =	6.63	in	Standard Value for 6" HDPE pipe, outside diameter
t =	0.736	in	Standard Value for 6" SDR 9 HDPE pipe, min wall thickness
μ =	0.3		Assumed Poisson Ratio
R_f =	571.04		Rigidity Factor, Calculated
D_f =	1.1		Deformation Factor taken from Figure 2-6, PE Handbook, Chapter 6, p230

$$\varepsilon_s = \frac{w * H}{144 * E_s}$$

Pipe Design by Wall Crushing and Wall Buckling
McCombs Landfill, Sector K - 05/10/12 (TLK)

Compressive Stress of 6" diameter perforated HDPE leachate collection pipe.

SDR =	11	Design Value

Find P_t

Soil Cover Depth (ft.) S_d =	8	Design Value
Waste Depth (ft.) W_d =	210	Design Value
Soil Cover Dens. (pcf) =	120	Standard Parameter
Waste Dens. (pcf) =	66.7	Standard Parameter

$$P_t = [(S_d * S_{Density}) + (W_d + W_{Density})]$$

P_t =	14967 PSF	Calculated
P_t =	**103.94 PSI**	Calculated

Calculate S_a

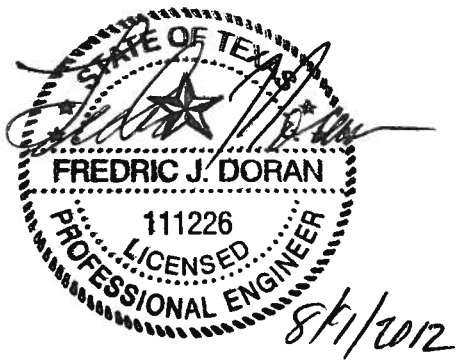
$$S_a = \frac{(SDR - 1)}{2} * P_t$$

S_a =	**519.69 PSI**	Calculated

Determine Buckling Capacity of the Pipe

$$P_{CB} = 0.8\sqrt{E' * P_C}$$

P_{CB} =	Critical Buckling Soil Pressure at Top of Pipe, PSI	
E' =	Soil Modulus. Value based on soil type (ASTM D2312) and degree of compaction.	
E' =	3000.00	Calculated
P_c =	Hydrostatic, Critical Collapse Differential Pressure (PSI)	
P_c (Driscopipe)=	$\frac{2.32 * E}{(SDR)^3}$	
E =	Stress and Time Dependent Tensile Modulus of Elasticity, PSI	
E =	35,000 PSI	Standard Value
P_c =	61.01	Calculated
P_{CB} =	**342.25**	Calculated
SF = Safety Factor		
SF = P_{CB} / P_t =	**3.29 > 2**	**OK**



Pipe Design by Compressive Ring Thrust Stress and Ring Deflection
McCombs Landfill, Sector K - 05/10/12 (TLK)

Compressive Ring Thrust Stress of 6" diameter perforated HDPE leachate collection pipe.

SDR = 11 Design Value

$$VAF = 0.88 - 0.71 * \frac{S_a - 1}{S_a + 2.5}$$

VAF = Vertical Arching Factor

S_a = Hoop Thrust Stiffness Ratio

$$S_a = \frac{1.43 * M_s * r_{CENT}}{EA}$$

r_{CENT} = radius to centroidal axis of pipe, in

M_s = one-dimensional modulus of soil, psi

E = apparent modulus of elasticity of pipe material, psi

A = profile wall average cross-sectional area, in2/in, or wall thickness (in) for DR pipe

Calculate Vertical Soil Stress = (depth * density)/144

Waste Depth (ft.) W_d =	210	ft	Design Value
Waste Dens. (pcf) =	66.7	pcf	Standard Parameter
Vertical Soil Stress =	97.271	psi	Calculated

Use Table 2-14 in PPI PE Handbook, Chapter 6, Page 226 to determine M_s

M_s =	3534.5	psi	(assuming a 90% compaction.)
r_{CENT} =	3.3125	in	
E =	28,250	psi	Standard Value for HDPE pipe, 50 year life (Table 2-6, Chapter 6, PE Handbook, p209)
A =	0.602	in	Minimum Wall thickness for SDR 11 pipe (Forrer Supply)
S_a =	**0.984**		Stiffness, Calculated
VAF =	**0.883**		Arching Factor, Calculated

Soil Cover Depth (ft.) S_d =	8		Design Value
Waste Depth (ft.) W_d =	210		Design Value
Soil Cover Dens. (pcf) =	120		Standard Parameter
Waste Dens. (pcf) =	66.7		Standard Parameter

$$P_{rd} = VAF * [(S_d * S_{Density}) + (W_d + W_{Density})]$$

P_{rd} =	13218.305	psf	Radial Directed Eart Pressure, Calculated
P_{rd} =	**91.79**	**psi**	Radial Directed Eart Pressure, Calculated

$$S = \frac{P_{rd} * D_o}{288 * A}$$

S =	**505.09**	**psi**	Ring Compressive Stress, Calculated
	<		
	1000	psi	Max Compressive Yield Strength for PE 3408 HDPE pipe (Handbook of Polyethylene Pipe, Appendix 3, pg 102)

OK

Calculated Pipe Deflection from Equipment

McCombs Landfill - Created by: TLK 7-3-12, Checked by: FJD 7-3-12

Assumptions: Critical Load occurs when:

Scenario 1) Construction equipment (CAT 770 off-road) driven over pipe trench (2-foot min cover)

Scenario 2) Compactor (CAT 826) driven over pipe with minimum 6-feet of waste in place

Input Variables for 6-inch Pipe

Scenario 1

OD (in.) =	6.625	
K =	0.1	pipe bedding constant (0.1)
D =	1.0	deflection lag factor (1.0)
E (psi) =	133,000	Pipe Mod of Elasticity
E' (psi) =	3,000	Soil Mod of Reaction
Soil Cover Depth (ft.) =	2	
Soil Cover Dens. (pcf) =	120	
Equipment Maximum Weight (psi) =	110	
D_p =	0.5	diameter of perforation (inches)
N =	2.4	number of perforations per foot

Equations:

t = OD/SDR	wall thickness
$I = t^3/12$	wall moment of inertia
R = 0.5[(OD+(OD-2t))/2]	mean radius
W = OD*[(Soil PSI)+(EQ PSI)]/14	vertical stress
$Wp = (W*12)/(12-(D_p*N))$	modified vertical stress
$x = (D*K*W*R^3) / [(E*I) + (0.061*E'*R^3)]$	deflection
Deflection % = x/(2*R)	

Design Criteria

Recommended Maximum Deflection	5.0%
Allowable Maximum Deflection	7.5%

Raba Kistner Leachate and Contaminated Water Plan

SAIC®

Memorandum

To: TCEQ

From: Cami Van Abel, P.E.

Subject: Raba Kistner Leachate and Contaminated Water Plan

Date: March 15, 2013

The Leachate and Contaminated Water Plan prepared by Raba Kistner Consultants, Inc. and dated April 24, 2002 (Revision 1 – July 29, 2002) is provided in partial form to provide details for contaminated water management for the updated leachate and contaminated water plan. The calculations prepared by Raba Kistner are still relevant to current conditions at the site and they comply with 30 TAC §330.305 (b) and (c). Sections 2 through 10, Figures Att15-2 through Att15-4, and Appendices Atta15-B through Att15-G have been removed from the Raba Kistner plan as they have been updated throughout Permit No. 729B.

Rainfall Frequency Maps Att15-A

LEACHATE AND CONTAMINATED WATER PLAN

1.0 CONTAMINATED WATER

Drainage and run-off from the active area that comes in direct contact with waste will be retained by temporary toe berms. These berms will be sized to hold the volume of water produced by the 24-hour, 25 year storm event assuming an active face of 250 ft x 250 ft (see Figure Att15-1). The assumed area of the active face is based on our experience for landfills with comparative waste disposal rates to the McCombs Landfill. The 24-hour, 25-year storm event maps from the Weather Bureau (NWS) Technical Paper 40, Rainfall Frequency Atlas of the United States can be found in Appendix Att15-A. Plate 1 of Appendix Att15-A displays a storm event map for the Central and Eastern United States, which includes the state of Texas. Plate 2 of Appendix Att15-A displays a storm event map with greater isopluvial detail for the area near the site. The two maps were compared with each other to obtain the 24-hour, 25-year storm event used in calculating the temporary toe berm and run-on berm sizes.

Calculations for sizing the temporary toe berms are as follows:

FOR PERMITTING ONLY,
NOT FOR CONSTRUCTION
Valerie Joosten 8/7/02

STATE OF TEXAS
VALERIE A. JOOSTEN
89118
LICENSED
PROFESSIONAL ENGINEER

Assumptions:

1. An active working face of 250 ft x 250 ft
2. Dikes/berms placed 50 ft down flow from active area
3. 24-hour, 25-year storm event = 3.0 inches = 0.25 ft
4. Active face 3:1 slope
5. Effective berm height = 2.0 ft (3.0 feet high minus 1.0 ft of freeboard)

Sample Calculation:

Maximum surface = 250 ft x (250 ft + 50 ft) = 75,000 ft²
Total rainfall volume = 75,000 ft² x .25 ft = 18,750 ft³
Volume retained by berm = 2 ft x (50 ft x 250 ft) + $\frac{2 \text{ ft} (3 \times 2 \text{ ft})}{2}$ x 250 ft = 26,500 ft³

26,500 ft³ retention volume/18,750 ft³ rainfall volume = 1.41 safety factor

Stormwater from areas with six (6) inches of daily cover and any area with alternate daily cover is considered contaminated. Inactive areas with six (6) inches of daily cover will be inspected weekly for erosion, ponded water, seeps, protruding waste or other conditions that may cause contaminated runoff from daily cover. After a period of 180 days, an additional six (6) inches of cover material will be placed over the daily cover for a total of not less than twelve (12) inches of cover. This 12-inch layer of cover material will be classified as "intermediate cover". Stormwater runoff from intermediate cover areas will be considered uncontaminated. Once the area becomes active again, the top six inches of intermediate cover material may be stripped off for use as daily cover in other areas.

Surface water run-on to the working face will be controlled with temporary run-on berms as shown on Figure Att15-1. Calculations for sizing the temporary run-on berms are as follows:

Assumptions:

1. 24-hour, 25 year storm event = 3.0 inches = 0.25 feet.
2. All surface water flow encountering run-on berms will be sheet flow.
3. Run-on berms are temporary with a maximum length of 300 ft centered on working face.
4. Berm height = 2.0 ft (24 in.)

Since flow to be handled by the run-on berm is sheet flow, the depth of water to be diverted will be 0.25 feet.

Sample calculation:

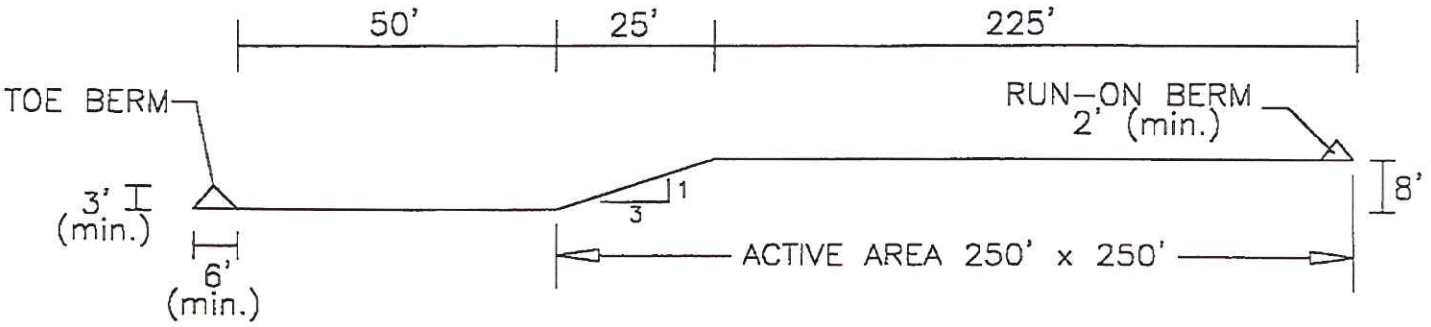
0.25 feet + 1.0 foot of freeboard = 1.25 feet (min.) berm height

2.0 feet (min.) constructed height/1.25 feet (min.) required height = 1.60 safety factor

Valerie Joosten 8/7/02

FOR PERMITTING ONLY,
NOT FOR CONSTRUCTION

FIGURES



TOE BERM CALCULATIONS

ASSUMPTIONS:

1. An active working face of 250' x 250'
2. Berms placed 50' download flow from active area
3. 24 hour–25 year storm event = 3" = 0.25 feet
4. Active face 3:1 slope
5. Effective berm height = 2' (24")
6. Berm height = 3' (36")(1.0' freeboard)

CALCULATIONS:

Max Surface = 250' x (250'+50') = 75,000 ft^2

Total rainfall volume = 75,000 ft^2 x .25' = 18,750 ft^3

Retention Volume

$$= 2'(50' \times 250') + \frac{2'(3' \times 2')}{2} \times 250' = 26{,}500\ ft^3$$

26,500 ft^3 retention volume/18,750 ft^3 rainfall volume = 1.41 Safety Factor

RUN–ON BERM CALCULATION

ASSUMPTIONS:

1. 24 hour–25 year storm event = 3" = 0.25 feet
2. All flows to run–on berms will be sheet flow
3. Run–on berms are temporary with a maximum length 300', centered on working face.
4. Berm 2.0' (24")

Since flows to be handled by the run–on berm are sheet flows, the depth of water to be diverted will be 0.25 feet.

CALCULATION:

0.25' + 1.0' freeboard = 1.25' (min) berm height

2' (min.) constructed height/1.25 (min.) required height = 1.60 Safety Factor

LINER QUALITY CONTROL PLAN
30 TAC §330.63(d)(4)(G), §330.331, §330.335, §330.337, §330.339, §330.341

This Liner Quality Control Plan (LQCP) has been prepared in accordance with 30 TAC §330.339 and details construction quality practices that will be undertaken to assure compliance with the Texas Commission on Environmental Quality (TCEQ) Municipal Solid Waste Rules (MSWR). This LQCP has been prepared using regulatory guidance documents, standard industry practices and testing methods current as of the issuance of this report. Quality assurance and quality control (QA/QC) practices for construction projects should follow the most up to date technical guidelines of the executive director. This LQCP provides QA/QC guidelines for the design, construction, testing parameters and frequency, and documentation of the landfill liner and leachate collection system construction.

3J.1 Scope

This LQCP is intended for construction of the sanitary landfill liner for the City of El Paso, Texas, McCombs Landfill (Landfill). The LQCP is intended to address 3 types of liner construction scenarios at the Landfill. The design structure of the liner system scenarios are described below.

Scenario 1 addresses a prescriptive (i.e., current permitted) liner system, consisting of (in ascending order):

- 6-inch scarified and compacted subgrade;
- 6-inch compacted caliche;
- 60-mil high density polyethylene (HDPE) geomembrane liner;
- 24-inch sand protective layer; and,
- Waste.

Scenario 2 describes an alternative liner system to Scenario 1 to be used in instances where caliche is not available for cell construction or is not cost effective to obtain. This scenario design system consists of (in ascending order):

- 6-inch scarified and compacted subgrade;
- Geosynthetic Clay Liner (GCL);
- 60-mil HDPE geomembrane liner;
- 24-inch sand protective layer; and,
- Waste.

Scenario 3 addresses a ”piggy-backed” liner system for portions of the Landfill where liner construction occurs over existing unlined municipal solid waste (MSW) fill areas. This scenario provides for a component of geotechnical stability where the

liner system is being constructed over waste fill areas with the potential for non-uniform settlement. This design system consists of (in ascending order, beginning with the waste material present at the time of "piggy-back" cell construction):

- Inert construction and demolition (C&D) waste;
- 12-inch intermediate cover;
- 36-inch compacted onsite soil;
- 6-inch bedding sand;
- Primary uniaxial geogrid;
- Secondary uniaxial geogrid;
- GCL;
- 60 mil HDPE geomembrane liner;
- 24-inch sand protective layer, and;
- Waste.

As stated previously, Scenario 1 and Scenario 2 liner systems are presented as interchangeable liner design systems and the use of either liner system will be determined based on the availability of caliche. Scenario 3 liner system is specific to the areas of the Landfill where waste material is considered in the foundation of the liner system for the "piggy-back" cell development.

The Landfill cell will be sloped to drain liquid to leachate collection trenches along the centerline of each cell. The leachate collection trenches will include a perforated HDPE pipe backfilled with aggregate. The leachate collection system is described further in Section 3J.5.1 and detailed in Appendix 3I.

3J.2 Construction Quality Assurance Personnel

All quality assurance personnel associated with Landfill cell construction will be properly trained and qualified to test and inspect the components of cell construction in their respective areas of expertise.

The Construction Quality Assurance (CQA) Professional of Record (POR) will be responsible for all CQA activities associated with liner system construction. The POR will be licensed as a Professional Engineer in Texas. The POR will be experienced in geotechnical engineering and/or engineering geology with relation to landfill cell construction.

The POR representative will be responsible for the implementation of field inspection and testing activities under the ~~direction~~ ***direct supervision*** of the POR. The POR representative is responsible for the CQA monitoring and must be an engineering technician with a minimum of 4 years relevant experience, or an engineer or geologist with at least 1 year of relevant experience.

Any references to surveying contained within this LQCP shall be required to be performed by a professional land surveyor registered in the State of Texas.

3J.3 Site Geology

Site geological information is described in Section 3.5 of the permit report. The liner system is designed with separation distance of over 300 feet from the highest observed groundwater elevation at the Landfill. Therefore, de-watering efforts or uplift analysis and ballast support is not required for landfill cell construction.

3J.4 Location

The landfill is located at 13600 McCombs Road, on the northeast side of the City of El Paso, Texas.

3J.5 Leachate Collection System Design

The leachate collection system shall be constructed according to construction drawings provided in Appendix 3G and consists of:

- Collection Trenches (ascending order):
  - 8-ounce geotextile filter fabric;
  - 8-inch diameter HDPE leachate collection perforated and non-perforated pipes;
  - 12-inch thick layer of washed aggregate (maximum of 5% of calcium carbonate content);
  - 12-inch thick layer of pea gravel backfill (maximum of 5% of calcium carbonate content); and,
  - 24-inch thick layer of protective sand.
- Leachate collection sump (ascending order):
  - 8-ounce geotextile filter fabric;
  - 18-inch diameter HDPE leachate transfer pipe;
  - 12-inch thick layer of washed aggregate (maximum of 5% of calcium carbonate content);
  - 12-inch thick layer of pea gravel backfill (maximum of 5% of calcium carbonate content); and,
  - 24-inch thick layer of protective sand.

3J.6 Site Preparation and Slopes

3J.6.1 Grading

The cell footprint should be prepared to the required grade prior to the construction of the liner system. All necessary grading and fill placement including side slopes shall be performed according to construction drawings. Anchor trenches shall be built as detailed in the construction drawings.

3J.6.2 Slopes

The slope of excavation faces shall be proportioned according to construction drawings and shall be in accordance with Occupational Safety and Health Administration (OSHA) excavation and trenching regulations.

A slope stability analysis is provided in Appendix 3-G, Attachment 3. The analysis is valid for the conditions and design set forth in the calculations.

Construction slopes shall not be steeper than the final slopes. No construction activities which may present concentrated loadings or stress, such as heavy equipment storage or soil stockpiles shall not be placed within 100 feet of slope crests unless additional slope stability analysis are performed.

3J.6.3 Excavation Faces Protective Layer

A 24-inch thick protective sand layer will be placed over the geomembrane as described in Section 3J.8.6. The protective layer will also act as a drainage media, allowing the transport of leachate to the low-lying leachate collection sump area. The intended sand to be used as protective layer will be sampled for material conformance as detailed in Table 3J.1. The POR representative will review the analytical results to ensure compliance with project specifications. The protective sand shall be placed directly on top of the geomembrane using a backhoe or belt conveyor. No construction equipment will be allowed to operate on the geomembrane without at least 12-inches of soil in place over the geomembrane. The remainder of the protective sand layer shall be placed using a low ground pressure dozer (see Table 3J-2).

3J.7 Material Field and Laboratory Testing

The ***P***OR will be responsible for the implementation of field inspection and testing activities. The Contractor, with oversight by the POR representative, will obtain soil and geosynthetic samples for third-party analysis. Laboratory and field tests are identified in Table 3J.1. The table presents testing requirements for pre-construction borrow source acceptance, placement requirements and post-placement requirements, where applicable. Additional tests may be required or recommended by the POR and/or POR representative prior to material acceptance. Other tests and services normally provided by inspection and testing agencies may also be conducted as the POR and/or POR representative directs.

Table 3J.1
Laboratory and Field QA/QC Testing

	Material	Test	Test Method	Minimum Test Frequency	Minimum Passing Requirements
1.	SUBGRADE (IN-SITU SOIL)			Prior to Grading	
		Particle Size Distribution	ASTM D 422 or ASTM D 1140	1 test/material type	≥ 30% passing 200 sieve; 100% passing 1 in. screen
		Standard Proctor Test	ASTM D 698	1 test/material type	NA

Laboratory and Field QA/QC Testing

Material	Test	Test Method	Minimum Test Frequency	Minimum Passing Requirements
		ASTM D 3042[10]		

Notes:

N/A – Not Applicable
MARV – Minimum Average Roll Value
[1] Permeability testing methodology described in 30 TAC §330.339 (c).
[2] Bentonite property tests performed at processing facility before shipment to GCL production facilities.
[3] Bentonite mass/area reported at 0% moisture content.
[4] All tensile testing shall be performed in the machine direction, with results as minimum average roll values unless otherwise indicated.
[5] Index flux and permeability testing with desired distilled/de-ionized water at 80 lb/in^2 (551 kPa) tailwater pressure.
[6] Peak value measured at 200 lb/ft^2 (30 kPa) normal stress.
[7] Interface friction angles shall be tested between the Subgrade/GCL, GCL/Geomembrane, and Geomembrane/Protective Sand to comply with calculations in Appendix 3G, Attachment 3.
[8] Four of 5 tests from each sample must have a shear strength no less than 95% of the minimum yield sheet strength, with the minimum acceptable shear strength no less than 120 lb/in, regardless of seaming method.
[9] For seams performed using hot wedge methods, 4 of 5 tests from each sample must have a peel strength no less than 62% of the minimum yield sheet strength, with the minimum acceptable peel strength of no less than 91 lb/in. For seams performed using extrusion fillet methods, 4 of 5 tests from each sample must have a peel strength of no less than 72% of the minimum yield sheet strength, with the minimum acceptable peel strength no less than 78 lb/in.
[10]The ASTM D 3042 test shall use a HCL solution having a pH of no more than 5.
[11]The pea gravel will act as a filter medium between the protective sand layer and the aggregate. Based on the gradation results of the 3 drainage material, the following criteria shall be met between all layers:

1. Criterion 1: $D_{15\ (lower)}/D_{85\ (upper)} < 4$ to 5
2. Criterion 2: $D_{15\ (lower)}/D_{15\ (upper)} < 20$

[12]Material conformance documentation will be provided by the contractor or contractor's selected geomembrane manufacturer to the POR prior to material delivery to the site.

3J.8 Material Placement

3J.8.1 Subgrade

To prepare the subgrade for cell construction, the area will initially be proof-rolled with heavy, rubber-tired construction equipment to detect "soft" areas or otherwise unsuitable issues for cell liner construction. Soft areas will be excavated and replaced with suitable onsite general fill material and re-compacted. Debris, including roots and stumps will be removed from the construction area. ***Areas determined to be unsuitable for cell liner construction will be excavated to the extent necessary to attain suitable conditions. The excavated area will be backfilled with material deemed suitable (soil material meeting the characteristics of Materials 1 or 2 listed in Table 3J.1) for cell liner construction. The material will be placed in lifts not exceeding 8-inches in thickness and compacted until the designed subgrade elevations in the area are attained. The backfilled material will be "stair-stepped" laterally into the native material as shown in Detail 3J-2 below. The surface of each of the steps in the surrounding subgrade will be scarified to maximize bonding between the new and old sections.***

The upper 6-inches of the subgrade will be scarified and roughened. Water will be added as necessary to provide a suitable firm subgrade so that optimum compaction density of not less than 95% of maximum density as determined by the standard proctor compaction test (ASTM D 698) is attained. The moisture content of the materials shall be uniform and within plus or minus 3% of optimum value as determined by ASTM D 2216. Required laboratory and field QA/QC tests, collection frequency and passing requirements are presented above in Table 3J.1. In place density and moisture testing will be conducted as described below in Section 3J.8.2. ***Construction will be sequenced in such a matter to maintain drainage and minimize the potential effects of precipitation on the construction area. Excavation activities will occur in strict adherence to OSHA regulations.***

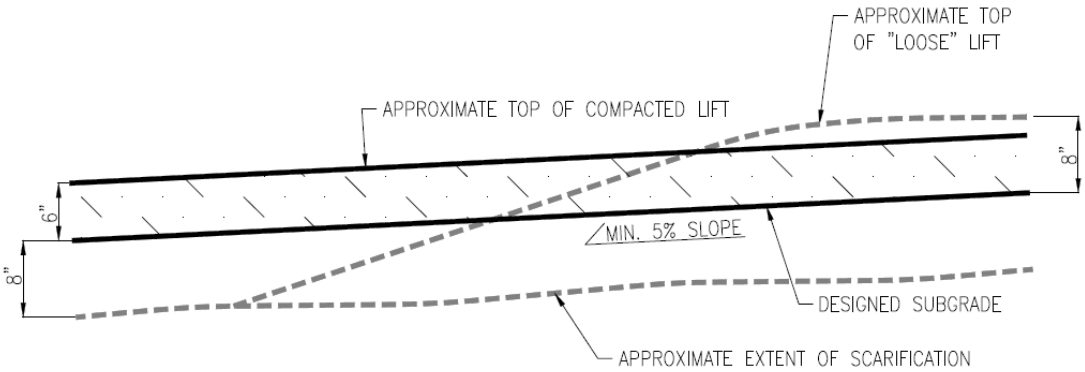
The POR representative will observe the subgrade preparation to ensure suitability for cell liner construction. The POR representative will verify the thickness of the subgrade through visual confirmation that the scarified and compacted in-situ soil is a minimum of 6-inches thick. Prior to the placement of the caliche (if used for the cell construction), the top of the finished subgrade will be surveyed for topographic elevations at a minimum rate of one survey point per 5,000 square feet of cell liner limits.

3J.8.2 Prescriptive Primary Liner – Caliche

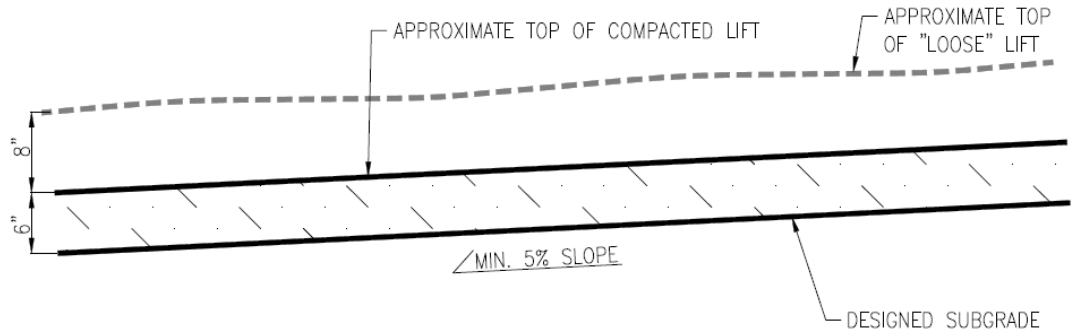
Once the finished, compacted subgrade is confirmed to adhere with material specifications and is surveyed, caliche material shall be placed in one lift not to exceed 8-inches in loose depth and then compacted to the required density of not less than 95% of maximum density as determined by the Standard Proctor Compaction Test (ASTM D 698). In instances where caliche is already present within the proposed construction area, approximately 8-inches of caliche material will be scarified as "loose" material and compacted to attain the 6-inch thickness requirements. ***If an area***

of the cell is determined to be unsuitable for in-situ liner construction, the identified area will be excavated to the extent necessary to attain suitable conditions. The excavated area will be backfilled with material deemed suitable (soil material meeting the characteristics of Material 2 listed in Table 3J.1) for cell liner construction. Excavations will be made in strict adherence to OSHA regulations. The backfill material will be placed in lifts not exceeding 8-inches in thickness and compacted until the designed subgrade elevations in the area are attained. The backfilled material will be "stair-stepped" laterally into the native material as shown in Detail 3J-2 below. The surface of each of the steps in the surrounding subgrade will be scarified to maximize bonding between the new and old sections.

Lift construction details are depicted in Figure 3J-1 ~~and 3J-2~~. The width of the lift construction will be dependent upon the cell area that will be constructed.



~~Figure 3J-1: Detail for Overexcavation and Recompaction of In-Situ Soils~~



~~Figure 3J-2: Detail for Compaction of Soils from Borrow Source~~

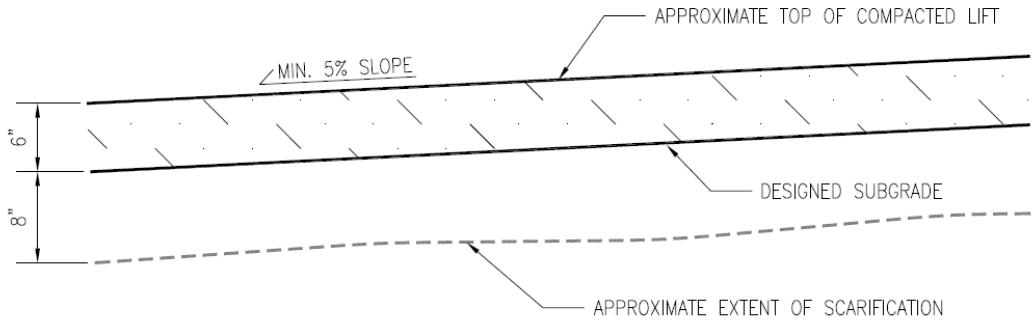


Figure 3J-1: Detail for Overexcavation and Recompaction of In-Situ Soils

The moisture content of the materials shall be uniform and within 2% of optimum value as determined by ASTM D 2216. Required laboratory and field QA/QC tests, collection frequency and passing requirements are presented above in Table 3J.1. Modeling of the alternative caliche (prescriptive) liner is provided in Appendix 3I, Attachment 2.

Compaction of the subgrade and the 6-inch caliche shall be performed with a pad-footed or prong-footed roller only. The soil liner shall not be compacted with a bulldozer, rubber-tired roller, flat-wheel roller, scraper or any tracked equipment unless it is used to pull a footed roller.

Determination of density and water content in the field shall be in accordance with the requirements of ASTM D 6938 (nuclear methods). Control of the soil placement shall consist of field inspection and testing to determine that the subgrade and the 6-inch caliche liner has been compacted to the required density and at the proper moisture content. Should any portion of a lift not conform to the density and moisture requirement, the lift shall be scarified, moisture conditioned as necessary, and re-compacted until the required density and moisture content are obtained.

Rocks and caliche clods greater than 1-inch in diameter shall total no more than 10% by weight. The caliche surface shall contain no material larger than 3/8-inches in diameter. The constructed subgrade and caliche shall be "stair-stepped" into an underlying formation of sufficient strength to ensure stability of the constructed liner system. The surface of each of the steps in the "old" liner shall be scarified to maximize bonding between the "old" and "new" liner material. See Figure 3J-~~3~~ ***2*** for depiction of the "stair-stepped" construction method. It should be noted that for the 6-inch caliche layer, there will only be one "stair-step".

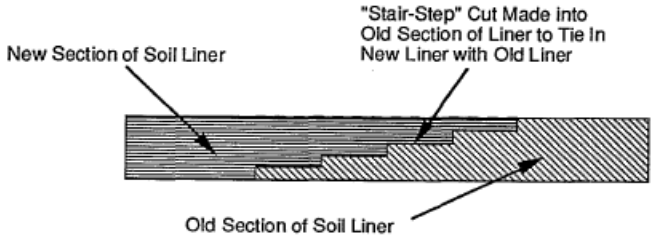

Figure 3J-~~3~~2: Tie-in of Soil Liner System (Typical)
Source of Figure: Figure 2.2, Quality Assurance and Quality Control for Waste Containment Facilities, EPA Technical Guidance Document 600/R-93/182, September 1993, p. 22

The completed compacted caliche soil liner must be protected against material drying, desiccation, rutting, erosion and ponding water. Any areas of noted damage shall be re-worked, re-compacted and re-tested.

The thickness of the in-place caliche will be verified by standard survey methods, using the same grid pattern and frequency (1 survey point per 5,000 square feet of cell liner limits) as the subgrade survey to verify that a finished, compacted thickness of at least 6-inches of caliche are in place.

The surface of a constructed soil liner should be covered or otherwise protected within a period of six months to mitigate the effects of dessication, surface erosion, and rutting due to traffic. Liner surfaces not covered within six months shall be checked by the POR and/or POR representative, who shall then submit a letter report on the findings to the TCEQ. Required repairs shall be performed promptly. A new ~~SLER~~ ***report*** shall be submitted on the new construction for all liners that need repair due to damage.

3J.8.3 Alternative Primary Liner – GCL

In instances where caliche material is not available (or not cost effective to obtain) for Landfill cell construction, GCL may be used. GCL is a manufactured hydraulic barrier consisting of clay bonded to layers of geosynthetics. The GCL shall be reinforced with a layer of sodium bentonite between a woven and a non-woven geotextile that are needle-punched together. Modeling of the alternative liner compared to the prescriptive liner utilizing the HELP model is provided in Appendix 3I, Attachment 1. Additionally, modeling of leachate migration using the Multimedia Exposure Assessment (Multimed) Model is provided in Appendix 3J, Attachment 1.

Quality control certificates shall be submitted by the GCL manufacturer and include: certificates of analysis for bentonite clay used in GCL production demonstrating compliance with the parameters swell index and fluid loss, and manufacturer's test data for finished GCL products of bentonite/mass area, GCL tensile strength, GCL peel strength, GCL index flux, permeability, and hydrated internal shear strength data demonstrating compliance with these specifications.

Handling of GCL rolls should be done to minimize potential damage. Procedures detailed in ASTM D-4873 (02), "Standard Guide for Identification, Storage and Handling of Geosynthetic Rolls and Samples" should be followed as applicable. Each roll shall be inspected during unloading to identify damage. Damaged rolls shall be set aside for further inspection. The GCL shall be stored in a level, dry and well-drained storage area, and shall be covered and protected from ultraviolet photodegradation and precipitation. Care will be taken during GCL roll loading and unloading so that not damage occurs to the GCL, its core or its protective wrapping. If any protective wrapping is damaged or stripped off the rolls, the wrapping will be repaired immediately or the roll moved to an enclosed facility until it may be repaired. If any of the clay material is found to be lost during transportation or handling, the outer layers of the GCL should be discarded until undamaged product is found. The reminder of the GCL roll will be re-wrapped in accordance with the manufacturer's instructions.

The GCL material physical property specifications are detailed Table 3J.1.

The minimum acceptable dimensions of full-size GCL panels shall be 150 feet in length and 15 feet in width. Short rolls (those manufactured to a length greater than 70 feet but less than a full-length roll) may be supplied at a rate no greater than 3 per truckload or 3 rolls every 36,000 square feet of GCL, whichever is less. A 6-inch overlap guideline shall be imprinted on both edges of the upper geotextile component of the GCL as a means for providing quality assurance of overlap dimension.

Installation shall not begin until the base has been properly prepared. The surface shall be maintained in a firm, clean, dry and smooth condition during liner installation. The GCL shall be oriented and installed with the non-woven side facing up. The panels shall lie flat on the underlying surface, with no wrinkles or folds, especially at the exposed edges of the panels. Equipment that could damage the GCL shall not be allowed to travel directly on the GCL, and the cover material (geomembrane) shall be placed immediately over the bentonite GCL.

As the GCL is installed, all overlapping panels shall be inspected to ensure that a minimum of 6-inch overlap exists. For any overlapping panels that are parallel to the slope, the upslope panel shall "single" over the downslope panel with a minimum of 24-inches of overlap. In addition, the GCL shall be inspected for any tears or punctures and repaired or replaced as deemed necessary by the POR.

3J.8.4 Geogrid and Bedding Sand

Scenario 3 described in Section 3J.1 includes 2 layers of uniaxial geogrid. Geogrids are reinforcement geosynthetics formed by adjoining longitudinal and transverse ribs. The geogrid layers are installed in areas of "piggy-back" Landfill development and underlie the GCL layer. A layer of free-draining bedding sand (buffer sand) no less than 6-inches thick will be placed between 36-inch compacted onsite soil and the primary uniaxial geogrid. The buffer sand will meet the specifications included in Table 3J.1. The buffer sand will be smooth-rolled and free of any rocks, debris or organic matter.

The POR or POR representative will inspect the delivered geogrid to verify it is the proper and intended material. The POR or POR representative will verify the geogrid identification labels and coding and inspect the rib joining, thickness and aperture size. If the geogrid has a primary strength direction, it must be indicated on the material.

The geogrid shall have a minimum tensile strength of 3,500 pounds per foot at an allowable stress of 5% or less over 50 years. Material conformance specifications are included in Table 3J.1. The geogrid installation contractor will demonstrate experience of at least 3 projects of similar construction and scope. The geogrid will be stored, handled and installed as specified in the manufacturer's recommendations and current industry standards. At a minimum, the geogrid installation requirements will include:

- Deployment will occur from the top of the slope downward, so that the geogrid is taut before the GCL is placed.
- Reinforcement shall be placed side by side with no overlap.
- The geogrid will end in an anchor trench as shown on Drawing P3-29.
- The roll ends will be connected with Bodkin connection only.

- The geogrid material shall be restrained from moving out of alignment during and after placement. Alignment shall be maintained by securing each reinforcement strip to the ground with stakes or anchoring by hand placing a small quantity of fill on top of the reinforcement prior to placement of the GCL.
- The reinforcement strips shall be pulled taut to remove slack. Stakes should be driven through the reinforcement apertures, or fill should be placed on top of the strips.
- The construction schedule shall allow only the amount of geogrid needed to complete immediately pending work in order to minimize unnecessary exposure to reinforcement.
- Overlying GCL placement shall proceed from the bottom of the slope upward.
- Construction equipment will not be permitted to drive directly over the geogrid.
- Geogrid roll connections on the side slopes shall be avoided. Connections will be located as close to the bottom of the slope as possible.

The POR or POR representative will also oversee the installation of the geogrid and approve connection methods. If additional conformance testing is required, the POR or POR representative will oversee sample collection, frequency and testing methodology.

3J.8.5 Secondary Liner – 60 mil HDPE Geomembrane

The liner system consists of a primary (caliche or alternative GCL) liner and the overlying secondary liner, which will consist of a 60-mil HDPE geomembrane. The geomembrane will be textured on both sides to ensure structural stability. The POR and/or POR representative will provide continuous construction oversight during the deployment of the geomembrane and will directly oversee testing of trial welds, seams and repairs. Documentation retained during the installation of the geomembrane will be used in preparation of the soil and geomembrane liner evaluation report (SLER and GLER).

Material conformance documentation will be provided by the contractor or the contractor's selected geomembrane manufacturer to the POR prior to material delivery to the site. Documentation provided will be reviewed by the POR to ensure the proposed material meets the properties specified in Table 3J.1, along with any other material requirements listed in the construction project specifications. Once the intended geomembrane material is approved for use by the POR for the construction project, the geomembrane may be shipped to the construction site.

The geomembrane rolls shipped to the site will be handled, transported and stored in accordance with the geomembrane manufacturer's recommendations, standard industry practices and as designated in the construction project specifications. Each roll will be identified with the manufacturer's name, product identification, thickness, roll number, roll dimensions and the date manufactured. The POR or POR representative will inspect the delivered rolls and will be provided with a roll inventory from the contractor. The POR or POR representative will verify the geomembrane rolls are stored and handled in accordance with the manufacturer's recommendations and observe that:

- Designated equipment used to unload and store the rolls do not have the potential to damage the liner material.
- The rolls are stored in a suitable location and not stacked more than 5 rolls high.
- The rolls are protected from potential puncture, dirt, grease, water accumulation, moisture and excessive heat.

The contractor will submit the qualifications of their selected geomembrane installer to the POR for approval. Geomembrane installation contractor qualifications will be described in the construction project specifications. At a minimum, these qualifications shall include:

- Sufficient production capacity and qualified personnel to meet the demands of the work.
- Approval or licensing of the geomembrane installer by the geomembrane manufacturer.
- Proven qualification by personnel performing the seaming operation by successfully passing seaming tests.
- A minimum of 1 million square feet of experience seaming geomembrane using the same type of seaming apparatus to be used for this work by the "Master Seamer".

Once approved, and prior to the geomembrane deployment, a meeting will be held at the construction site with a minimum of the POR and/or POR representative, the contractor and the approved geomembrane installer in attendance. Installation methods, testing frequency, nonconformance procedures, deployment layout, schedule and personnel contact information will be discussed, at a minimum. Prior to geomembrane deployment, the geomembrane installer will inspect the prepared surface to ensure it is suitable for liner installation, and will certify it in a subgrade acceptance form. If caliche is used as the primary liner, it should be smooth drum rolled, free of irregularities, ruts, soft areas, loose soil, stones, protrusions or any objects that could damage the geomembrane. If GLC is used as the primary liner, the material integrity will be inspected, and the surface should be clean, and kept free of irregularities or any debris or wind-blown material.

The POR or POR representative will observe geomembrane deployment procedures and facilitate sample collection and testing. Geomembrane rolls shall be deployed by equipment that will unroll the geomembrane without damaging, crimping or stretching the material and that will not damage the underlying material. The geomembrane will not be installed on frozen subgrade. If GCL is used in the liner design, deployment equipment will not be permitted to ride directly over the GCL. If the geomembrane panel must be adjusted once placed upon the GCL, the panel must be moved by hand or using a small pneumatic, tired lifting unit. Tire inflation pressure should be limited to 40 kPa (6 psi) or less over the GCL. If there are any folds, wrinkles or other undulations in the GCL, they will be removed prior to placement of the geomembrane.

The POR and/or POR representative will remain onsite during geomembrane installation. The panels will each be uniquely identified and the location of each panel recorded on a drawing. All panels must be anchored with sufficient ballast to prevent wind uplift. Restrictions will be placed on the liner installation personnel to minimize

the potential for damage to the liner, such as smoking or wearing damaging shoes. No more panels will be deployed than can be seamed on the same day.

During geomembrane deployment, the POR and/or POR representative will:

- Observe handling, storage, and installation procedures used for geomembrane liner to verify conformance with manufacturer's instructions and construction specifications.
- Verify that equipment used in geomembrane installation and testing is operating properly.
- Verify that installer is performing trial seaming and field testing at the required frequencies.
- Inspect geomembrane during placement for defects and damage. Notify the contractor for repairs.
- Observation to ensure the unrolled geomembrane has adequate and appropriate ballast to prevent uplift from the wind without causing damage to the geomembrane.
- Observation of the weather conditions (i.e., temperature, humidity, precipitation and wind) to ensure they are acceptable for geomembrane placement and seaming.
- Inspect to ensure the leading edge excavation of the anchor trench excavation is rounded and the dimensions are as specified.
- Inspect to verify proper slack is incorporated into liner sheet installation to accommodate effects from temperature changes.
- Document the construction using field notes and photographs.
- Verify that the installer is documenting all necessary information. Make periodic reviews of installer's documentation.
- Locate, identify, and send seam and material samples to the testing agency for specified tests listed in Table 3J.1.
- Oversee field testing to verify proper procedures and quality construction. Testing frequencies are included in Table 3J.1.
- Review test results from laboratory and field tests. Passing criteria for laboratory and field tests are presented in Table 3J.1.

Panels that are not deployed in accordance with manufacturer's recommendations, standard industry practices and/or as specified in this LQCP or in the construction project specifications shall be marked by the POR representative and be repaired or be removed and replaced by the installer.

The QA/QC program for geomembrane seaming includes preparing trial seams prior to seaming each day as well as throughout the day, inspection and testing of field seams, and repairing seams that fail testing criteria.

Trial seams should be performed daily for each welding machine: before the day's field seaming begins, and once every 4 hours (a minimum of twice per day). Trial seam welds will be inspected by liner manufacturer's site personnel to allow for determination of the optimum welding process parameters based on the prevailing

ambient conditions. Trial welds should be at least 5 feet long, and 1½-feet wide. Each trial weld should be marked with the date, time, ambient temperature, number of seaming unit, name of seamer, pass or fail designation, and peel and sheer strength values. The peel and sheer strength values are to be determined using the installer's supplied digital electronically operated tensiometer testing device operated by the installer's personnel and monitored by the POR and/or POR representative. Three peel tests will be performed on each trial seam weld and recorded on the trial seam. The results will be documented and filed on the report forms, and each trial seam will be stored onsite until the GLER is approved by the TCEQ.

The entire length of each field seam weld will be visually inspected immediately after production by the POR representative and the installer's representative. In addition, the entire length of each seam weld will be nondestructively tested and certified for continuity and water-tightness in the presence of the POR representative using air pressure or other appropriate methods. The results will be recorded daily on a Seam Testing Information form. Factory seams are subject to the same testing requirements as field seams.

The air channel that results between the dual bonded tracks will be inflated using a hypodermic needle and pressurized to approximately 200 kPa (30 pounds per square inch(psi)). ***The designated time period for the seam test shall be no less than 5 minutes.*** ~~There is no limit as to the length of seam that is tested. If the pressure drops within an allowable amount in the designated time period (typically 5 minutes), the seam is deemed acceptable.~~ If an unacceptable drop in pressure ***(4 psi or more)*** occurs, a number of actions may be taken:

- The distance may be systematically halved until the leak is located.
- The section may be tested by some other leak detection method.
- An extrusion fillet weld may be placed over the entire edge.
- A cap strip may be seamed over the entire edge.

For non-destructive seam testing using a vacuum chamber or vacuum box will be performed by placing a transparent top over the seam. A soapy solution is placed over the seam. A vacuum of approximately 20 kPa (or 3 psi) is then applied. The top is held over the seam for approximately 10 seconds. When a leak is encountered, the soapy solution shows bubbles, which reduces the observed vacuum. If the vacuum is held and no bubbles observed, the test is deemed acceptable. Vacuum box testing will only be applied in areas where a level testing surface is present. Vacuum box testing will not occur over areas of the leachate collection sumps, anchor trenches, pipe penetrations or any other locations where the vacuum box top will not be able to provide a seal over the test area.

Destructive seam testing may be performed per the construction project specification. The destructive test samples should be cut at least 3 feet in length and 1½-feet wide to provide 3 relatively equal samples: 1 for the independent laboratory to test in peel and shear; 1 for the installer to check in the field; and 1 for an archive sample. The seam should be field tested in peel at the time the sample is taken.

If the field test fails, the seam can either be reconstructed between the failed field test location and any previous passed seam location, or the installer can move to either side

of the failed seam location (10-foot minimum), and take another sample for field testing. If the sample passes the field test, a destructive sample is taken from that location and sent for laboratory tests. If the laboratory sample passes the test, the seam is reconstructed between the 2 passing tests. If the laboratory tests fail, the process is repeated until both the field and laboratory samples pass the tests at a location. The seam is then reconstructed in this zone between 2 passed test reconstructed seams. All acceptable seams must be bound by 2 passed tests.

Any samples or in-place destructive testing of geomembrane will require that the area affected be repaired or replaced with material of equal or better quality. Such repair or replacement is subject to the same nondestructive testing as other geomembrane liner seams.

To meet the seaming requirement discussed above, field testing and inspection of geomembrane seaming will include:

- Observation to ensure the seaming materials and equipment are as specified.
- Observation to ensure a firm foundation is available for seaming.
- Observation to ensure the start-up seams prepared by the installer and their testing meet the requirements of the specifications prior to actual seaming.
- Observation to ensure the geomembrane is free from dirt, dust, and moisture.
- Inspection to ensure the overlap of the sheets composing the seam is in conformance with specifications.
- Measurement of the curing time between seaming and seam testing to ensure that it is as specified (when applicable).
- Observation to ensure that all seams are free from visible discontinuities in the seam or any other noticeable defects. Defective areas shall be marked on the liner and on the construction inspection form. All defective areas are required to be repaired in accordance with the specifications.
- Observation of air pressure or other appropriate methods of nondestructively testing field seams to ensure the testing is completed as specified.
- Observation of destructive test sampling to ensure samples are taken at the location and frequency specified.
- Observation of the repair and retesting of seams at failure points in accordance with the specifications to ensure the repaired seams meet the criteria specified.
- Walk-through inspection of the liner after placement of the geomembrane to ensure that equipment or personnel have not damaged the geomembrane during the seaming process.
- Completion of applicable inspection forms.

Repairs, installation and/or material defects in seams, failing destructive and/or non-destructive tests and destructive test sample locations shall be repaired by 1 of the following acceptable repair techniques:

- Patches – used to repair large holes, tears, defects and destructive test locations.

- Extrusion – used to repair small holes, tears, defects, holes from non-destructive tests and seam defects less than ½-inch in length or diameter.
- Capping – used to repair failed seams or seams where non-destructive testing can be performed.

Repairs will be performed in accordance with standard industry practices and will be inspected and logged by the POR representative. The surface of the repair area will be clean and dry. Patching material will be extended at least 6-inches beyond the defect area and, with beveled edges prior to extrusion welding.

Once the geomembrane has been inspected and deemed acceptable by the POR and/or POR representative, the top of the geomembrane liner will be surveyed using the same grid pattern and frequency (one survey point per 5,000 square feet of cell liner limits) as the subgrade if the GCL was used as the primary liner.

The geomembrane will be tested for potential holes and liner defects again after the protective sand layer has been placed over the geomembrane. The leak location detection testing will be performed in accordance with ASTM D 6747.

3J.8.6 Protective Sand Layer

A 24-inch thick protective sand layer will be placed over the geomembrane. The protective layer will also act as drainage media, allowing the transport of leachate to the low-lying leachate collection sump area. The intended sand to be used as protective layer will be sampled for material conformance as detailed in Table 3J.1. The POR representative will review the analytical results to ensure compliance with project specifications. The protective sand shall be placed directly on top of the geomembrane using a backhoe or belt conveyor. No construction equipment shall be allowed to operate on the geomembrane without a minimum thickness of 12-inches of sand in place over the geomembrane. The protective sand layer shall be placed using a low ground pressure dozer in accordance with the requirements in Table 3J-2.

Table 3J-2
Construction Equipment Requirements

Maximum Allowable Equipment Ground Pressure (psi)	Thickness of Overlying Compacted Fill (ft)
< 4	1.0
< 8	1.5
<16	2.0
>16	3.0

The POR representative will observe protective sand layer placement and document construction activities using field notes, surveys and photographs. The POR representative will observe material placement process to ensure the Contractor's equipment does not damage the geomembrane and that the minimum thickness of sand over the geomembrane is as specified for the type of equipment in use. The protective sand shall be placed from the haul road and spread in a manner to minimize wrinkles and

stress in the underlying geosynthetics. The protective sand will be placed from the cell bottom to the top along the sideslopes. Any geosynthetic material that has been damaged by the installation of the protective sand layer must be repaired and re-tested using methods described in Section 3J.8.5.

The POR and/or POR representative will review the in-place laboratory testing results to ensure permeability specifications are attained.

Thickness verification of the protective sand layer shall be determined by standard survey methods. The base measurement will be either the top of the geomembrane (if GCL is used for the primary liner) or the top of the finished caliche. A survey of the top of the finished protective sand layer will be performed using the same grid pattern of one measurement per 5,000 square feet of lined area.

3J.8.7 Leachate Collection

The leachate collection trench design is described in Appendix 3I. All soil testing and evaluation of either in-situ soil or constructed soil liners shall be complete prior to installing the leachate collection system. An 8-ounce woven geotextile cushion will be placed along the leachate collection trench, on top of the HDPE geomembrane to protect the geomembrane from the overlying leachate collection pipe and drainage aggregate. The POR and/or POR representative will review the contractor material submittal to ensure the product is suitable for geomembrane protection. The leachate collection pipe will be overlain by 12-inches of washed aggregate. An additional 12-inches of washed pea gravel will be placed over the aggregate to act as a filter medium between the protective sand layer and the aggregate. The washed aggregate and pea gravel will meet the material specifications listed in Table 3J.1. The POR and/or POR representative will review the laboratory analytical data to ensure the intended aggregate and pea gravel are in conformance with the material specifications. Additional inspection activities that will be performed by the POR and/or POR representative for the leachate collection aggregate and pea gravel include:

- Field observation to ensure the geotextile cushion material is placed through the entire extent of the leachate collection trench, and the material used is the type and thickness specified.
- Field observation to ensure the filter material is of the type and gradation specified.
- Field observation to ensure the filter material placement follows the specified installation procedures, including the minimum thickness requirements.

The protective sand layer survey data will be used to verify that 2-feet total of aggregate and pea gravel have been placed over the leachate collection trench, along with field verification that each layer of filter material is 1-foot thick.

The leachate collection pipe shall be placed as shown on the design drawings. The pipe shall be joined in accordance with manufacturer and project construction specifications.

Construction equipment shall not be allowed to travel directly over the leachate collection pipes until adequate cover has been placed (see Table 3J-2).

The POR and/or POR representative will review material data sheets to ensure the intended pipe meets construction specifications. During the installation of the pipe, the POR and/or POR representative will:

- Inspect the condition of the pipes and note any defects. Any identified defective pipe must be replaced.
- Observe that construction equipment is operated in a manner to prevent damage to the pipe.
- Inspect the pipe perforations and pipe orientation to verify they are placed as detailed in the construction specifications.
- Observe that the pipes and fittings are joined in accordance with manufacturer and construction project specifications.
- Observe that the pipe is handled and placed in a manner to prevent materials (rocks, debris, vegetation, etc.) from entering the pipe.

3J.8.8 Reports

Three copies of prepared construction documentation reports will be submitted to the TCEQ Municipal Solid Waste Permits Section. The evaluated construction project will not be used for waste disposal until TCEQ approval is received. It is expected that TCEQ may respond to the permittee either verbally or by writing within 14 days from the date of submittal listed on the SLER and GLER. If no response is received within 14 days of the SLER and GLER submittal, the report shall be considered accepted and the permittee will begin waste disposal.

Each report will be signed and, where necessary, sealed by the individual performing the evaluation and countersigned by the permittee or authorized representative.

Permanent markers will be installed during the cell construction to identify the extent of permissible waste limits. Once the cell is approved for use, initial waste placement will proceed as detailed in Section 4.9.9.

Preparation and submission of the SLER and GLER shall be in accordance with TCEQ MSWD and will include necessary field reports, laboratory analytical reports and surveys to document the construction methods and test procedures are consistent with this LQCP, TCEQ rules and construction project specifications. At a minimum, the SLER and GLER shall contain the following:

- A schedule and summary of construction activities;
- A summary of all laboratory analytical and field test results;
- Observe that construction equipment is operated in a manner to prevent damage to the pipe;
- Location of field samples and test results;
- Statement of compliance with the LQCP and/or description of deviations from the LQCP and/or project construction specifications;
- Record drawings and surveys;
- Detailed description of temporary dewatering activities as necessary; and,

- Seal and signature of POR and, if applicable, POR representative, in accordance with the Texas Engineering Practice Act.

Any deviations from this LQCP shall receive prior written approval from the executive director.

Appendix 3J
LINER QUALITY CONTROL PLAN
30 TAC §330.63(d)(4)(G), §330.331, §330.335, §330.337, §330.339, §330.341

This Liner Quality Control Plan (LQCP) has been prepared in accordance with 30 TAC §330.339 and details construction quality practices that will be undertaken to assure compliance with the Texas Commission on Environmental Quality (TCEQ) Municipal Solid Waste Rules (MSWR). This LQCP has been prepared using regulatory guidance documents, standard industry practices and testing methods current as of the issuance of this report. Quality assurance and quality control (QA/QC) practices for construction projects should follow the most up to date technical guidelines of the executive director. This LQCP provides QA/QC guidelines for the design, construction, testing parameters and frequency, and documentation of the landfill liner and leachate collection system construction.

3J.1 Scope

This LQCP is intended for construction of the sanitary landfill liner for the City of El Paso, Texas, McCombs Landfill (Landfill). The LQCP is intended to address 3 types of liner construction scenarios at the Landfill. The design structure of the liner system scenarios are described below.

Scenario 1 addresses a prescriptive (i.e., current permitted) liner system, consisting of (in ascending order):

- 6-inch scarified and compacted subgrade;
- 6-inch compacted caliche;
- 60-mil high density polyethylene (HDPE) geomembrane liner;
- 24-inch sand protective layer; and,
- Waste.

Scenario 2 describes an alternative liner system to Scenario 1 to be used in instances where caliche is not available for cell construction or is not cost effective to obtain. This scenario design system consists of (in ascending order):

- 6-inch scarified and compacted subgrade;
- Geosynthetic Clay Liner (GCL);
- 60-mil HDPE geomembrane liner;
- 24-inch sand protective layer; and,
- Waste.

Scenario 3 addresses a ”piggy-backed” liner system for portions of the Landfill where liner construction occurs over existing unlined municipal solid waste (MSW) fill areas. This scenario provides for a component of geotechnical stability where the

liner system is being constructed over waste fill areas with the potential for non-uniform settlement. This design system consists of (in ascending order, beginning with the waste material present at the time of "piggy-back" cell construction):

- Inert construction and demolition (C&D) waste;
- 12-inch intermediate cover;
- 36-inch compacted onsite soil;
- 6-inch bedding sand;
- Primary uniaxial geogrid;
- Secondary uniaxial geogrid;
- GCL;
- 60 mil HDPE geomembrane liner;
- 24-inch sand protective layer, and;
- Waste.

As stated previously, Scenario 1 and Scenario 2 liner systems are presented as interchangeable liner design systems and the use of either liner system will be determined based on the availability of caliche. Scenario 3 liner system is specific to the areas of the Landfill where waste material is considered in the foundation of the liner system for the "piggy-back" cell development.

The Landfill cell will be sloped to drain liquid to leachate collection trenches along the centerline of each cell. The leachate collection trenches will include a perforated HDPE pipe backfilled with aggregate. The leachate collection system is described further in Section 3J.5.1 and detailed in Appendix 3I.

3J.2 Construction Quality Assurance Personnel

All quality assurance personnel associated with Landfill cell construction will be properly trained and qualified to test and inspect the components of cell construction in their respective areas of expertise.

The Construction Quality Assurance (CQA) Professional of Record (POR) will be responsible for all CQA activities associated with liner system construction. The POR will be licensed as a Professional Engineer in Texas. The POR will be experienced in geotechnical engineering and/or engineering geology with relation to landfill cell construction.

The ~~Owner's Representative (OR)~~ ***POR representative*** will be responsible for the implementation of field inspection and testing activities, under the direction of the POR. The ***P***OR ***representative*** is responsible for the CQA monitoring and must be an engineering technician with a minimum of 4 years relevant experience, or an engineer or geologist with at least 1 year of relevant experience.

Any references to surveying contained within this LQCP shall be required to be performed by a professional land surveyor registered in the State of Texas.

3J.3 Site Geology

Site geological information is described in Section 3.5 of the permit report. The liner system is designed with separation distance of over 300 feet from the highest observed groundwater elevation at the Landfill. Therefore, de-watering efforts or uplift analysis and ballast support is not required for landfill cell construction.

3J.4 Location

The landfill is located at 13600 McCombs Road, on the northeast side of the City of El Paso, Texas.

3J.5 Leachate Collection System Design

The leachate collection system shall be constructed according to construction drawings provided in Appendix 3G and consists of:

- Collection Trenches (ascending order):
  - 8-ounce geotextile filter fabric;
  - 8-inch diameter HDPE leachate collection perforated and non-perforated pipes;
  - 12-inch thick layer of washed aggregate (maximum of 5% of calcium carbonate content);
  - 12-inch thick layer of pea gravel backfill (maximum of 5% of calcium carbonate content); and,
  - 24-inch thick layer of protective sand.
- Leachate collection sump (ascending order):
  - 8-ounce geotextile filter fabric;
  - 18-inch diameter HDPE leachate transfer pipe;
  - 12-inch thick layer of washed aggregate (maximum of 5% of calcium carbonate content);
  - 12-inch thick layer of pea gravel backfill (maximum of 5% of calcium carbonate content); and,
  - 24-inch thick layer of protective sand.

3J.6 Site Preparation and Slopes

3J.6.1 Grading

The cell footprint should be prepared to the required grade prior to the construction of the ~~composite~~ liner system. All necessary grading and fill placement including side slopes shall be performed according to construction drawings. Anchor trenches shall be built as detailed in the construction drawings.

3J.6.2 Slopes

The slope of excavation faces shall be proportioned according to construction drawings and shall be in accordance with Occupational Safety and Health Administration (OSHA) excavation and trenching regulations.

A slope stability analysis is provided in Appendix 3-G, Attachment 3. The analysis is valid for the conditions and design set forth in the calculations.

Construction slopes shall not be steeper than the final slopes. No construction activities which may present concentrated loadings or stress, such as heavy equipment storage or soil stockpiles shall not be placed within 100 feet of slope crests unless additional slope stability analysis are performed.

3J.6.3 Excavation Faces Protective Layer

A 24-inch thick protective sand layer will be placed over the geomembrane as described in Section 3J.8.6. The protective layer will also act as a drainage media, allowing the transport of leachate to the low-lying leachate collection sump area. The intended sand to be used as protective layer will be sampled for material conformance as detailed in Table 3J.1. The ***P***OR ***representative*** will review the analytical results to ensure compliance with project specifications. The protective sand shall be placed directly on top of the geomembrane using a backhoe or belt conveyor. No construction equipment will be allowed to operate on the geomembrane without at least 12-inches of soil in place over the geomembrane. The remainder of the protective sand layer shall be placed using a low ground pressure dozer (see Table 3J-2).

3J.7 Material Field and Laboratory Testing

The OR will be responsible for the implementation of field inspection and testing activities. The Contractor, with oversight by the ***P***OR ***representative***, will obtain soil and geosynthetic samples for third-party analysis. Laboratory and field tests are identified in Table 3J.1. The table presents testing requirements for pre-construction borrow source acceptance, placement requirements and post-placement requirements, where applicable. Additional tests may be required or recommended by the POR and/or ***P***OR ***representative*** prior to material acceptance. ~~Minimum passing criteria may be modified based on the site design considerations (i.e. available borrow source material, unforeseen site conditions) during the preparation of the project plans and specifications.~~ Other tests and services normally provided by inspection and testing agencies may also be conducted as the POR and/or ***P***OR ***representative*** directs.

Table 3J.1
Laboratory and Field QA/QC Testing

	Material	Test	Test Method	Minimum Test Frequency	Minimum Passing Requirements
1.	SUBGRADE (IN-SITU SOIL)			Prior to Grading	
		Particle Size Distribution	ASTM D 422 or ASTM D 1140	1 test/material type	≥ 30% passing 200 sieve; 100% passing 1 in. screen
		Standard Proctor Test	ASTM D 698	1 test/material type	N/A
		Moisture Content	ASTM D 2216	1 test/material type	NA
				~~In-Place~~ *During Placement*	
		Field Density and Water Content (Nuclear Methods)	ASTM D 6938	1/8,000 ft^2 per 6 in. lift	≥95% Maximum Dry Density ± 3% optimum moisture

Table 3J.1
Laboratory and Field QA/QC Testing

Material	Test	Test Method	Minimum Test Frequency	Minimum Passing Requirements

Notes:

N/A – Not Applicable
MARV – Minimum Average Roll Value
[1] Permeability testing methodology described in 30 TAC §330.339 (c)~~(4)(A).~~
[2] Bentonite property tests performed at processing facility before shipment to GCL production facilities.
[3] Bentonite mass/area reported at 0% moisture content.
[4] All tensile testing shall be performed in the machine direction, with results as minimum average roll values unless otherwise indicated.
[5] Index flux and permeability testing with desired distilled/de-ionized water at 80 lb/in^2 (551 kPa) tailwater pressure.
[6] Peak value measured at 200 lb/ft^2 (30 kPa) normal stress.
[7] Interface friction angles shall be tested between the Subgrade/GCL, GCL/Geomembrane, and Geomembrane/Protective Sand to comply with calculations in Appendix 3G, Attachment 3.
[8] Four of 5 tests from each sample must have a shear strength no less than 95% of the minimum yield sheet strength, with the minimum acceptable shear strength no less than 120 lb/in, regardless of seaming method.
[9] For seams performed using hot wedge methods, 4 of 5 tests from each sample must have a peel strength no less than 62% of the minimum yield sheet strength, with the minimum acceptable peel strength of no less than 91 lb/in. For seams performed using extrusion fillet methods, 4 of 5 tests from each sample must have a peel strength of no less than 72% of the minimum yield sheet strength, with the minimum acceptable peel strength no less than 78 lb/in.
[10]The ASTM D 3042 test shall use a HCL solution having a pH of no more than 5.
[11]The pea gravel will act as a filter medium between the protective sand layer and the aggregate. Based on the gradation results of the 3 drainage material, the following criteria shall be met between all layers:

1. Criterion 1: $D_{15\ (lower)}/D_{85\ (upper)} < 4$ to 5
2. Criterion 2: $D_{15\ (lower)}/D_{15\ (upper)} < 20$

3J.8 Material Placement

3J.8.1 Subgrade

To prepare the subgrade for cell construction, the area will initially be proof-rolled with heavy, rubber-tired construction equipment to detect "soft" areas or otherwise unsuitable issues for cell liner construction. Soft areas will be excavated and replaced with suitable onsite general fill material and re-compacted. Debris, including roots and stumps will be removed from the construction area.

The upper 6-inches of the subgrade will be scarified and roughened. Water will be added as necessary to provide a suitable firm subgrade so that optimum compaction density of not less than 95% of maximum density as determined by the standard proctor compaction test (ASTM D 698) is attained. The moisture content of the materials shall be uniform and within plus or minus 3% of optimum value as determined by ASTM D 2216. Required laboratory and field QA/QC tests, collection frequency and passing requirements are presented above in Table 3J.1. In place density and moisture testing will be conducted as described below in Section 3J.8.2.

The ***P***OR ***representative*** will observe the subgrade preparation to ensure suitability for cell liner construction. The ***P***OR ***representative*** will verify the thickness of the subgrade through visual confirmation that the scarified and compacted in-situ soil is a minimum of 6-inches thick. Prior to the placement of the caliche (if used for the cell construction), the top of the finished subgrade will be surveyed for topographic elevations at a minimum rate of one survey point per 5,000 square feet of cell liner limits.

3J.8.2 Prescriptive Primary Liner – Caliche

Once the finished, compacted subgrade is confirmed to adhere with material specifications and is surveyed, caliche material shall be placed in one lift not to exceed 8-inches in loose depth and then compacted to the required density of not less than 95% of maximum density as determined by the Standard Proctor Compaction Test (ASTM D 698). ***In instances where caliche is already present within the proposed construction area, approximately 8-inches of caliche material will be scarified as "loose" material and compacted to attain the 6-inch thickness requirements. Lift construction details are depicted in Figure 3J-1 and 3J-2. The width of the lift construction will be dependent upon the cell area that will be constructed.***

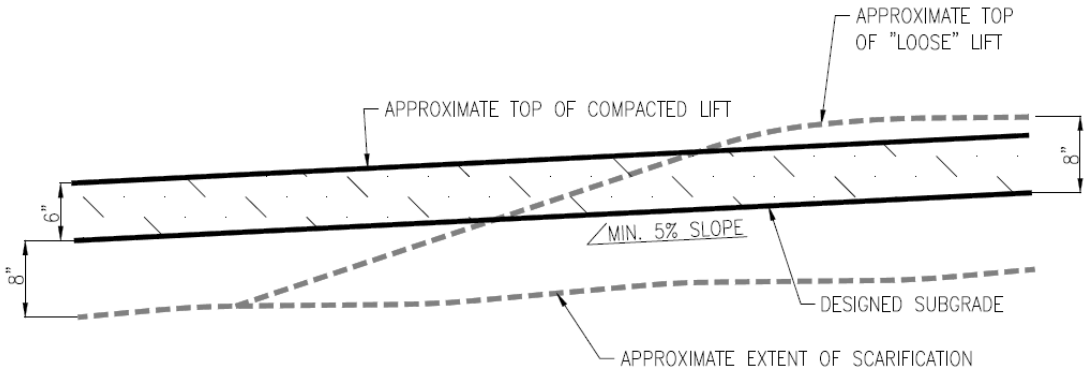

Figure 3J-1: Detail for Overexcavation and Recompaction of In-Situ Soils

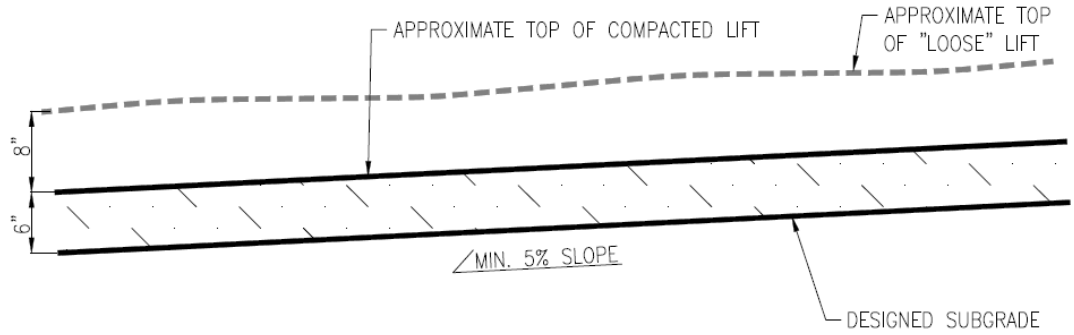

Figure 3J-2: Detail for Compaction of Soils from Borrow Source

The moisture content of the materials shall be uniform and within 2% of optimum value as determined by ASTM D 2216. Required laboratory and field QA/QC tests, collection frequency and passing requirements are presented above in Table 3J.1. Modeling of the alternative caliche (prescriptive) liner is provided in Appendix 3I, Attachment 2.

Compaction of the subgrade and the 6-inch caliche shall be performed with a pad-footed or prong-footed roller only. The soil liner shall not be compacted with a bulldozer, rubber-tired roller, flat-wheel roller, scraper or any tracked equipment unless it is used to pull a footed roller.

Determination of density and water content in the field shall be in accordance with the requirements of ASTM D 6938 (nuclear methods). Control of the soil placement shall consist of field inspection and testing to determine that the subgrade and the 6-inch caliche liner has been compacted to the required density and at the proper moisture content. Should any portion of a lift not conform to the density and moisture requirement, the lift shall be scarified, moisture conditioned as necessary, and re-compacted until the required density and moisture content are obtained.

Rocks and caliche clods greater than 1-inch in diameter shall total no more than 10% by weight. The caliche surface shall contain no material larger than 3/8-inches in diameter. The constructed subgrade and caliche shall be “stair-stepped” into an underlying formation of sufficient strength to ensure stability of the constructed liner

system. The surface of each of the steps in the "old" liner shall be scarified to maximize bonding between the "old" and "new" liner material. See Figure 3J-~~1~~ ***3*** for depiction of the "stair-stepped" construction method. It should be noted that for the 6-inch caliche layer, there will only be one "stair-step".

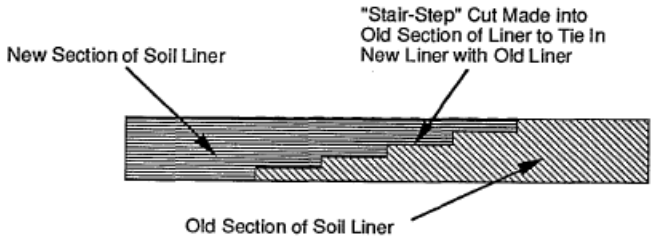

Figure 3J-~~1~~ *3*: Tie-in of Soil Liner System (Typical)
Source of Figure: Figure 2.2, Quality Assurance and Quality Control for Waste Containment Facilities, EPA Technical Guidance Document 600/R-93/182, September 1993, p. 22

The completed compacted caliche soil liner must be protected against material drying, desiccation, rutting, erosion and ponding water. Any areas of noted damage shall be re-worked, re-compacted and re-tested.

The thickness of the in-place caliche will be verified by standard survey methods, using the same grid pattern and frequency (1 survey point per 5,000 square feet of cell liner limits) as the subgrade survey to verify that a finished, compacted thickness of at least 6-inches of caliche are in place.

The surface of a constructed soil liner should be covered or otherwise protected within a period of six months to mitigate the effects of dessication, surface erosion, and rutting due to traffic. Liner surfaces not covered within six months shall be checked by the POR and/or ***P***OR ***representative***, who shall then submit a letter report on the findings to the TCEQ. Required repairs shall be performed promptly. A new SLER shall be submitted on the new construction for all liners that need repair due to damage.

3J.8.3 Alternative Primary Liner – GCL

In instances where caliche material is not available (or not cost effective to obtain) for Landfill cell construction, GCL may be used. GCL is a manufactured hydraulic barrier consisting of clay bonded to layers of geosynthetics. The GCL shall be reinforced with a layer of sodium bentonite between a woven and a non-woven geotextile that are needle-punched together. Modeling of the alternative liner compared to the prescriptive liner utilizing the HELP model is provided in Appendix 3I, Attachment 1. Additionally, modeling of leachate migration using the Multimedia Exposure Assessment (Multimed) Model is provided in Appendix 3J, Attachment 1.

Quality control certificates shall be submitted by the GCL manufacturer and include: certificates of analysis for bentonite clay used in GCL production demonstrating compliance with the parameters swell index and fluid loss, and manufacturer's test data for finished GCL products of bentonite/mass area, GCL tensile strength, GCL peel strength, GCL index flux, permeability, and hydrated internal shear strength data demonstrating compliance with these specifications.

Handling of GCL rolls should be done to minimize potential damage. Procedures detailed in ASTM D-4873 (02), "Standard Guide for Identification, Storage and Handling of Geosynthetic Rolls and Samples" should be followed as applicable. Each roll shall be inspected during unloading to identify damage. Damaged rolls shall be set aside for further inspection. The GCL shall be stored in a level, dry and well-drained storage area, and shall be covered and protected from ultraviolet photodegradation and precipitation. Care will be taken during GCL roll loading and unloading so that not damage occurs to the GCL, its core or its protective wrapping. If any protective wrapping is damaged or stripped off the rolls, the wrapping will be repaired immediately or the roll moved to an enclosed facility until it may be repaired. If any of the clay material is found to be lost during transportation or handling, the outer layers of the GCL should be discarded until undamaged product is found. The reminder of the GCL roll will be re-wrapped in accordance with the manufacturer's instructions.

The GCL material physical property specifications are detailed Table 3J.1.

The minimum acceptable dimensions of full-size GCL panels shall be 150 feet in length and 15 feet in width. Short rolls (those manufactured to a length greater than 70 feet but less than a full-length roll) may be supplied at a rate no greater than 3 per truckload or 3 rolls every 36,000 square feet of GCL, whichever is less. A 6-inch overlap guideline shall be imprinted on both edges of the upper geotextile component of the GCL as a means for providing quality assurance of overlap dimension.

Installation shall not begin until the base has been properly prepared. The surface shall be maintained in a firm, clean, dry and smooth condition during liner installation. The GCL shall be oriented and installed with the non-woven side facing up. The panels shall lie flat on the underlying surface, with no wrinkles or folds, especially at the exposed edges of the panels. Equipment that could damage the GCL shall not be allowed to travel directly on the GCL, and the cover material (geomembrane) shall be placed immediately over the bentonite GCL.

As the GCL is installed, all overlapping panels shall be inspected to ensure that a minimum of 6-inch overlap exists. For any overlapping panels that are parallel to the slope, the upslope panel shall "single" over the downslope panel with a minimum of 24-inches of overlap. In addition, the GCL shall be inspected for any tears or punctures and repaired or replaced as deemed necessary by the POR.

3J.8.4 Geogrid and Bedding Sand

Scenario 3 described in Section 3J.1 includes 2 layers of uniaxial geogrid. Geogrids are reinforcement geosynthetics formed by adjoining longitudinal and transverse ribs. The geogrid layers are installed in areas of "piggy-back" Landfill development and underlie the GCL layer. A layer of free-draining bedding sand (buffer sand) no less than 6-inches thick will be placed between 36-inch compacted onsite soil and the primary uniaxial geogrid. The buffer sand will meet the specifications included in Table 3J.1. The buffer sand will be smooth-rolled and free of any rocks, debris or organic matter.

The ***P***OR ***or POR representative*** will inspect the delivered geogrid to verify it is the proper and intended material. The ***P***OR ***or POR representative*** will verify the geogrid

identification labels and coding and inspect the rib joining, thickness and aperture size. If the geogrid has a primary strength direction, it must be indicated on the material.

The geogrid shall have a minimum tensile strength of 3,500 pounds per foot at an allowable stress of 5% or less over 50 years. Material conformance specifications are included in Table 3J.1. The geogrid installation contractor will demonstrate experience of at least 3 projects of similar construction and scope. The geogrid will be stored, handled and installed as specified in the manufacturer's recommendations and current industry standards. At a minimum, the geogrid installation requirements will include:

- Deployment will occur from the top of the slope downward, so that the geogrid is taut before the GCL is placed.
- Reinforcement shall be placed side by side with no overlap.
- The geogrid will end in an anchor trench as shown on Drawing P3-29.
- The roll ends will be connected with Bodkin connection only.
- The geogrid material shall be restrained from moving out of alignment during and after placement. Alignment shall be maintained by securing each reinforcement strip to the ground with stakes or anchoring by hand placing a small quantity of fill on top of the reinforcement prior to placement of the GCL.
- The reinforcement strips shall be pulled taut to remove slack. Stakes should be driven through the reinforcement apertures, or fill should be placed on top of the strips.
- The construction schedule shall allow only the amount of geogrid needed to complete immediately pending work in order to minimize unnecessary exposure to reinforcement.
- Overlying GCL placement shall proceed from the bottom of the slope upward.
- Construction equipment will not be permitted to drive directly over the geogrid.
- Geogrid roll connections on the side slopes shall be avoided. Connections will be located as close to the bottom of the slope as possible.

The ***POR or P***OR ***representative*** will also oversee the installation of the geogrid and approve connection methods. If additional conformance testing is required, the ***POR or P***OR ***representative*** will oversee sample collection, frequency and testing methodology.

3J.8.5 Secondary Liner – 60 mil HDPE Geomembrane

The ~~composite~~ liner system consists of a primary (caliche or alternative GCL) liner and the overlying secondary liner, which will consist of a 60-mil HDPE geomembrane. The geomembrane will be textured on both sides to ensure structural stability. The POR and/or ***P***OR ***representative*** will provide continuous construction oversight during the deployment of the geomembrane and will directly oversee testing of trial welds, seams and repairs. Documentation retained during the installation of the geomembrane will be used in preparation of the soil and geomembrane liner evaluation report (SLER and GLER).

Material conformance documentation will be provided by the contractor or the contractor's selected geomembrane manufacturer to the POR prior to material delivery to the site. Documentation provided will be reviewed by the POR to ensure the proposed material meets the properties specified in Table 3J.1, along with any other material requirements listed in the construction project specifications. Once the intended geomembrane material is approved for use by the POR for the construction project, the geomembrane may be shipped to the construction site.

The geomembrane rolls shipped to the site will be handled, transported and stored in accordance with the geomembrane manufacturer's recommendations, standard industry practices and as designated in the construction project specifications. Each roll will be identified with the manufacturer's name, product identification, thickness, roll number, roll dimensions and the date manufactured. The POR or ***P***OR ***representative*** will inspect the delivered rolls and will be provided with a roll inventory from the contractor. The POR or ***P***OR ***representative*** will verify the geomembrane rolls are stored and handled in accordance with the manufacturer's recommendations and observe that:

- Designated equipment used to unload and store the rolls do not have the potential to damage the liner material.
- The rolls are stored in a suitable location and not stacked more than 5 rolls high.
- The rolls are protected from potential puncture, dirt, grease, water accumulation, moisture and excessive heat.

The contractor will submit the qualifications of their selected geomembrane installer to the POR for approval. Geomembrane installation contractor qualifications will be described in the construction project specifications. At a minimum, these qualifications shall include:

- Sufficient production capacity and qualified personnel to meet the demands of the work.
- Approval or licensing of the geomembrane installer by the geomembrane manufacturer.
- Proven qualification by personnel performing the seaming operation by successfully passing seaming tests.
- A minimum of 1 million square feet of experience seaming geomembrane using the same type of seaming apparatus to be used for this work by the "Master Seamer".

Once approved, and prior to the geomembrane deployment, a meeting will be held at the construction site with a minimum of the POR and/or ***P***OR ***representative***, the contractor and the approved geomembrane installer in attendance. Installation methods, testing frequency, nonconformance procedures, deployment layout, schedule and personnel contact information will be discussed, at a minimum. Prior to geomembrane deployment, the geomembrane installer will inspect the prepared surface to ensure it is suitable for liner installation, and will certify it in a subgrade acceptance form. If caliche is used as the primary liner, it should be smooth drum rolled, free of irregularities, ruts, soft areas, loose soil, stones, protrusions or any objects that could damage the geomembrane. If GLC is used as the primary liner, the

material integrity will be inspected, and the surface should be clean, and kept free of irregularities or any debris or wind-blown material.

The POR or ***P***OR ***representative*** will observe geomembrane deployment procedures and facilitate sample collection and testing. Geomembrane rolls shall be deployed by equipment that will unroll the geomembrane without damaging, crimping or stretching the material and that will not damage the underlying material. The geomembrane will not be installed on frozen subgrade. If GCL is used in the ~~composite~~ liner design, deployment equipment will not be permitted to ride directly over the GCL. If the geomembrane panel must be adjusted once placed upon the GCL, the panel must be moved by hand or using a small pneumatic, tired lifting unit. Tire inflation pressure should be limited to 40 kPa (6 psi) or less over the GCL. If there are any folds, wrinkles or other undulations in the GCL, they will be removed prior to placement of the geomembrane.

The POR and/or ***P***OR ***representative*** will remain onsite during geomembrane installation. The panels will each be uniquely identified and the location of each panel recorded on a drawing. All panels must be anchored with sufficient ballast to prevent wind uplift. Restrictions will be placed on the liner installation personnel to minimize the potential for damage to the liner, such as smoking or wearing damaging shoes. No more panels will be deployed than can be seamed on the same day.

During geomembrane deployment, the POR and/or ***P***OR ***representative*** will:

- Observe handling, storage, and installation procedures used for geomembrane liner to verify conformance with manufacturer's instructions and construction specifications.
- Verify that equipment used in geomembrane installation and testing is operating properly.
- Verify that installer is performing trial seaming and field testing at the required frequencies.
- Inspect geomembrane during placement for defects and damage. Notify the contractor for repairs.
- Observation to ensure the unrolled geomembrane has adequate and appropriate ballast to prevent uplift from the wind without causing damage to the geomembrane.
- Observation of the weather conditions (i.e., temperature, humidity, precipitation and wind) to ensure they are acceptable for geomembrane placement and seaming.
- Inspect to ensure the leading edge excavation of the anchor trench excavation is rounded and the dimensions are as specified.
- Inspect to verify proper slack is incorporated into liner sheet installation to accommodate effects from temperature changes.
- Document the construction using field notes and photographs.
- Verify that the installer is documenting all necessary information. Make periodic reviews of installer's documentation.

- Locate, identify, and send seam and material samples to the testing agency for specified tests listed in Table 3J.1.
- Oversee field testing to verify proper procedures and quality construction. Testing frequencies are included in Table 3J.1.
- Review test results from laboratory and field tests. Passing criteria for laboratory and field tests are presented in Table 3J.1.

Panels that are not deployed in accordance with manufacturer's recommendations, standard industry practices and/or as specified in this LQCP or in the construction project specifications shall be marked by the ***P***OR ***representative*** and be repaired or be removed and replaced by the installer.

The QA/QC program for geomembrane seaming includes preparing trial seams prior to seaming each day as well as throughout the day, inspection and testing of field seams, and repairing seams that fail testing criteria.

Trial seams should be performed daily for each welding machine: before the day's field seaming begins, and once every 4 hours (a minimum of twice per day). Trial seam welds will be inspected by liner manufacturer's site personnel to allow for determination of the optimum welding process parameters based on the prevailing ambient conditions. Trial welds should be at least 5 feet long, and 1½-feet wide. Each trial weld should be marked with the date, time, ambient temperature, number of seaming unit, name of seamer, pass or fail designation, and peel and sheer strength values. The peel and sheer strength values are to be determined using the installer's supplied digital electronically operated tensiometer testing device operated by the installer's personnel and monitored by the POR and/or ***P***OR ***representative***. Three peel tests will be performed on each trial seam weld and recorded on the trial seam. The results will be documented and filed on the report forms, and each trial seam will be stored onsite until the GLER is approved by the TCEQ.

The entire length of each field seam weld will be visually inspected immediately after production by the ***P***OR ***representative*** and the installer's representative. In addition, the entire length of each seam weld will be nondestructively tested and certified for continuity and water-tightness in the presence of the ***P***OR ***representative*** using air pressure or other appropriate methods. The results will be recorded daily on a Seam Testing Information form. ***Factory seams are subject to the same testing requirements as field seams.***

The air channel that results between the dual bonded tracks will be inflated using a hypodermic needle and pressurized to approximately 200 kPa (30 pounds per square inch(psi)). There is no limit as to the length of seam that is tested. If the pressure drops within an allowable amount in the designated time period (typically 5 minutes), the seam is deemed acceptable. If an unacceptable drop in pressure occurs, a number of actions may be taken:

- ***The distance may be systematically halved until the leak is located.***
- ***The section may be tested by some other leak detection method.***
- ***An extrusion fillet weld may be placed over the entire edge.***
- ***A cap strip may be seamed over the entire edge.***

For non-destructive seam testing using a vacuum chamber or vacuum box will be performed by placing a transparent top over the seam. A soapy solution is placed over the seam. A vacuum of approximately 20 kPa (or 3 psi) is then applied. The top is held over the seam for approximately 10 seconds. When a leak is encountered, the soapy solution shows bubbles, which reduces the observed vacuum. If the vacuum is held and no bubbles observed, the test is deemed acceptable. Vacuum box testing will only be applied in areas where a level testing surface is present. Vacuum box testing will not occur over areas of the leachate collection sumps, anchor trenches, pipe penetrations or any other locations where the vacuum box top will not be able to provide a seal over the test area.

Destructive seam testing may be performed per the construction project specification. The destructive test samples should be cut at least 3 feet in length and 1½-feet wide to provide 3 relatively equal samples: 1 for the independent laboratory to test in peel and shear; 1 for the installer to check in the field; and 1 for an archive sample. The seam should be field tested in peel at the time the sample is taken.

If the field test fails, the seam can either be reconstructed between the failed field test location and any previous passed seam location, or the installer can move to either side of the failed seam location (10-foot minimum), and take another sample for field testing. If the sample passes the field test, a destructive sample is taken from that location and sent for laboratory tests. If the laboratory sample passes the test, the seam is reconstructed between the 2 passing tests. If the laboratory tests fail, the process is repeated until both the field and laboratory samples pass the tests at a location. The seam is then reconstructed in this zone between 2 passed test reconstructed seams. All acceptable seams must be bound by 2 passed tests.

Any samples or in-place destructive testing of geomembrane will require that the area affected be repaired or replaced with material of equal or better quality. Such repair or replacement is subject to the same nondestructive testing as other geomembrane liner seams.

To meet the seaming requirement discussed above, field testing and inspection of geomembrane seaming will include:

- Observation to ensure the seaming materials and equipment are as specified.
- Observation to ensure a firm foundation is available for seaming.
- Observation to ensure the start-up seams prepared by the installer and their testing meet the requirements of the specifications prior to actual seaming.
- Observation to ensure the geomembrane is free from dirt, dust, and moisture.
- Inspection to ensure the overlap of the sheets composing the seam is in conformance with specifications.
- Measurement of the curing time between seaming and seam testing to ensure that it is as specified (when applicable).
- Observation to ensure that all seams are free from visible discontinuities in the seam or any other noticeable defects. Defective areas shall be marked on the liner and on the construction inspection form. All defective areas are required to be repaired in accordance with the specifications.

- Observation of air pressure or other appropriate methods of nondestructively testing field seams to ensure the testing is completed as specified.
- Observation of destructive test sampling to ensure samples are taken at the location and frequency specified.
- Observation of the repair and retesting of seams at failure points in accordance with the specifications to ensure the repaired seams meet the criteria specified.
- Walk-through inspection of the liner after placement of the geomembrane to ensure that equipment or personnel have not damaged the geomembrane during the seaming process.
- Completion of applicable inspection forms.

Repairs, installation and/or material defects in seams, failing destructive and/or non-destructive tests and destructive test sample locations shall be repaired by 1 of the following acceptable repair techniques:

- Patches – used to repair large holes, tears, defects and destructive test locations.
- Extrusion – used to repair small holes, tears, defects, holes from non-destructive tests and seam defects less than ½-inch in length or diameter.
- Capping – used to repair failed seams or seams where non-destructive testing can be performed.

Repairs will be performed in accordance with standard industry practices and will be inspected and logged by the ***P***OR ***representative***. The surface of the repair area will be clean and dry. Patching material will be extended at least 6-inches beyond the defect area and, with beveled edges prior to extrusion welding.

Once the geomembrane has been inspected and deemed acceptable by the POR and/or ***P***OR ***representative***, the top of the geomembrane liner will be surveyed using the same grid pattern and frequency (one survey point per 5,000 square feet of cell liner limits) as the subgrade if the GCL was used as the primary liner.

The geomembrane will be tested for potential holes and liner defects again after the protective sand layer has been placed over the geomembrane. The leak location detection testing will be performed in accordance with ASTM D 6747.

3J.8.6 Protective Sand Layer

A 24-inch thick protective sand layer will be placed over the geomembrane. The protective layer will also act as drainage media, allowing the transport of leachate to the low-lying leachate collection sump area. The intended sand to be used as protective layer will be sampled for material conformance as detailed in Table 3J.1. The ***P***OR ***representative*** will review the analytical results to ensure compliance with project specifications. The protective sand shall be placed directly on top of the geomembrane using a backhoe or belt conveyor. No construction equipment shall be allowed to operate on the geomembrane without a minimum thickness of 12-inches of sand in place over the geomembrane. The protective sand layer shall be placed using a low ground pressure dozer in accordance with the requirements in Table 3J-2.

Table 3J-2
Construction Equipment Requirements

Maximum Allowable Equipment Ground Pressure (psi)	Thickness of Overlying Compacted Fill (ft)
< 4	1.0
< 8	1.5
<16	2.0
>16	3.0

The ***P***OR ***representative*** will observe protective sand layer placement and document construction activities using field notes, surveys and photographs. The ***P***OR ***representative*** will observe material placement process to ensure the Contractor's equipment does not damage the geomembrane and that the minimum thickness of sand over the geomembrane is as specified for the type of equipment in use. The protective sand shall be placed from the haul road and spread in a manner to minimize wrinkles and stress in the underlying geosynthetics. The protective sand will be placed from the cell bottom to the top along the sideslopes. Any geosynthetic material that has been damaged by the installation of the protective sand layer must be repaired and re-tested using methods described in Section 3J.8.5.

The POR and/or ***P***OR ***representative*** will review the in-place laboratory testing results to ensure permeability specifications are attained.

Thickness verification of the protective sand layer shall be determined by standard survey methods. The base measurement will be either the top of the geomembrane (if GCL is used for the primary liner) or the top of the finished caliche. A survey of the top of the finished protective sand layer will be performed using the same grid pattern of one measurement per 5,000 square feet of lined area.

3J.8.7 Leachate Collection

The leachate collection trench design is described in Appendix 3I. ***All soil testing and evaluation of either in-situ soil or constructed soil liners shall be complete prior to installing the leachate collection system***. An 8-ounce woven geotextile cushion will be placed along the leachate collection trench, on top of the HDPE geomembrane to protect the geomembrane from the overlying leachate collection pipe and drainage aggregate. The POR and/or ***P***OR ***representative*** will review the contractor material submittal to ensure the product is suitable for geomembrane protection. The leachate collection pipe will be overlain by 12-inches of washed aggregate. An additional 12-inches of washed pea gravel will be placed over the aggregate to act as a filter medium between the protective sand layer and the aggregate. The washed aggregate and pea gravel will meet the material specifications listed in Table 3J.1. The POR and/or ***P***OR ***representative*** will review the laboratory analytical data to ensure the intended aggregate and pea gravel are in conformance with the material specifications. Additional inspection activities that will be performed by the POR and/or ***P***OR ***representative*** for the leachate collection aggregate and pea gravel include:

- Field observation to ensure the geotextile cushion material is placed through the entire extent of the leachate collection trench, and the material used is the type and thickness specified.
- Field observation to ensure the filter material is of the type and gradation specified.
- Field observation to ensure the filter material placement follows the specified installation procedures, including the minimum thickness requirements.

The protective sand layer survey data will be used to verify that 2-feet total of aggregate and pea gravel have been placed over the leachate collection trench, along with field verification that each layer of filter material is 1-foot thick.

The leachate collection pipe shall be placed as shown on the design drawings. The pipe shall be joined in accordance with manufacturer and project construction specifications.

Construction equipment shall not be allowed to travel directly over the leachate collection pipes until adequate cover has been placed (see Table 3J-2).

The POR and/or ***P***OR ***representative*** will review material data sheets to ensure the intended pipe meets construction specifications. During the installation of the pipe, the POR and/or ***P***OR ***representative*** will:

- Inspect the condition of the pipes and note any defects. Any identified defective pipe must be replaced.
- Observe that construction equipment is operated in a manner to prevent damage to the pipe.
- Inspect the pipe perforations and pipe orientation to verify they are placed as detailed in the construction specifications.
- Observe that the pipes and fittings are joined in accordance with manufacturer and construction project specifications.
- Observe that the pipe is handled and placed in a manner to prevent materials (rocks, debris, vegetation, etc.) from entering the pipe.

3J.8.8 Reports

Three copies of prepared construction documentation reports will be submitted to the TCEQ Municipal Solid Waste ~~Division (MSWD)~~ ***Permits Section***. The evaluated construction project will not be used for waste disposal until TCEQ approval is received. It is expected that TCEQ may respond to the permittee either verbally or by writing within 14 days from the date of submittal listed on the SLER and GLER. If no response is received within 14 days of the SLER and GLER submittal, the report shall be considered accepted and the permittee will begin waste disposal.

Each report will be signed and, where necessary, sealed by the individual performing the evaluation and countersigned by the permittee or authorized representative.

Permanent markers will be installed during the cell construction to identify the extent of permissible waste limits. Once the cell is approved for use, initial waste placement will proceed as detailed in Section 4.9.9.

Preparation and submission of the SLER and GLER shall be in accordance with TCEQ MSWD and will include necessary field reports, laboratory analytical reports and surveys to document the construction methods and test procedures are consistent with this LQCP, TCEQ rules and construction project specifications. At a minimum, the SLER and GLER shall contain the following:

- A schedule and summary of construction activities;
- A summary of all laboratory analytical and field test results;
- Observe that construction equipment is operated in a manner to prevent damage to the pipe;
- Location of field samples and test results;
- Statement of compliance with the LQCP and/or description of deviations from the LQCP and/or project construction specifications;
- Record drawings ***and surveys***;
- Detailed description of temporary dewatering activities as necessary; and,
- Seal and signature of POR and, if applicable, ***P***OR ***representative***, in accordance with the Texas Engineering Practice Act.

Any deviations from this LQCP shall receive prior written approval from the executive director.

Appendix 3J – Attachment 1
Multimed Modeling Results

SAIC®

SAIC®

Appendix 3J, Attachment 1
MultiMed Groundwater Fate and Transport Model for Alternative Landfill Liner Design

Introduction

SAIC, on behalf of the City of El Paso, Texas has prepared a permit amendment for the vertical expansion of the McCombs Landfill. This vertical expansion within the currently permitted landfill footprint will increase the ultimate waste disposal capacity of the Landfill. In addition to the permit amendment for a vertical expansion, SAIC is proposing an alternative liner design utilizing a geocomposite liner (GCL) liner system. The Multimedia Exposure Assessment (MultiMed) model was completed as part of the alternative liner design to evaluate the potential impacts to groundwater associated with the landfill development and the alternative liner design and to ensure compliance with the contituents listed within Table 1 of 30 TAC §330.331.

Landfill Liner

The McCombs Landfill currently uses an alternative liner design that was approved on July 10, 1995. The approved liner (referenced as "Scenaro 1") consists of (from bottom to top), 6-inches of compacted subgrade, 6-inches of caliche, 60-mil high density polyethylene (HDPE) geomembrane liner and 24-inches protective soil cover.

The proposed alternative liner design (referred to as"Scenaro 2") for the McCombs Landfill is as follows (from bottom to top):

- 6-inch compacted subgrade;
- GCL;
- 60-mil HDPE geomembrane liner;
- 24-inch protective cover; and
- Waste.

Based on the results of the HELP modeling, the combination of HDPE geomembrane liner with GCL provides a lower permeability barrier system with a leakage rate through the modeled barrier system subgrade of 0.000015 inch per day (in/d) or 1.39E-04 meters per year (m/y). [0.000015 in/d *0.0254m/in * 365d/y =0.000139 m/y].

The HELP model was run to evaluate several scenarios as part of the alternative liner approval and copies of the HELP model runs are provided in Appendix 3I, Attachment 1. Based the on various scenarios, HELP model runs were completed for this permit amendment. The peak daily percolation/leakage value predicted through the GCL subgrade layer of the alternative liner design for each scenario is 0.000015 inch, as depicted in the table below.

HELP Model Runs

McCombs Landfill Alternative Liner Design

Permit Amendment MSW 729B

Alternative Liner Design	GCL Layer	Peak Leakage Values (inches/day)	Peak Daily Values for Years:	Appendix 3I, Attachment 1 (Page #)
Open Conditions: 10 ft MSW, 6" Daily Cover	Layer 7	0.000015	1 through 4	19
Open Conditions: 264ft MSW, 12" Intermediate Cover	Layer 8	0.000015	1 through 20	40
Closed Condition: Prescribed Final Cover	Layer 12	0.000015	1 through 30	72
Closed Condition: Prescribed Final Cover (Sideslope)	Layer 12	0.000015	1 through 30	104
Closed Condition: Final Cover_EVAP	Layer 11	0.000015	1 through 30	128
Close Condition: Final Cover EVAP (Sideslope)	Layer 10	0.000015	1 through 30	156

Site Geology and Hydrogeology

The McCombs Landfill is located on deposits of the Hueco Bolson, probably Camp Rice Formation. These deposits primarily consist of clay, sand, and gravel, with some caliche. The landfill site is underlain by Tertiary and Quaternary basin (Bolson) deposits, overlain by areas of gravel and caliche rimrock. Recent Quaternary alluvial deposits are also present in the Landfill vicinity in topographically low areas.

Boring logs for wells drilled on site to depths greater than 500 feet generally indicate deposits of:

- 0 – 50 feet Sand, and sand and gravel;
- 50-250 feet Sand, with some clay;
- 250-470 feet Sand and fine gravel mix; and
- 470-560 feet Sandy clay.

In general, the relatively clean sands are non-plastic, while sandy clay ranges from low to high plasticity. Permeability tests were not considered necessary based on the soil types encountered during the site characterization. Estimated coefficients of permeability are between 0.01 and 0.04 centimeters per second.

The regional groundwater system in the area primarily consists of the Hueco Bolson aquifers. The Hueco Bolson is divided into the City Artesian area, the Mesa area and the Lower Valley (Leggart, 1962). The Mesa area extends north of the City Artesian area into New Mexico and east to the Hueco Mountains. The Landfill is located within the Mesa area.

Two aquifers occur in these areas: an upper aquifer in the Rio Grande alluvium and a lower aquifer in the Hueco Bolson deposits. Since no known impermeable zone of regional extent separates these aquifers, the Rio Grande alluvium and the Hueco Bolson are considered to be, at least in part, hydrologically connected in the City Artesian and Lower Valley areas (Alvared and Buckner, 1980). The Mesa area primarily consists of Hueco Bolson deposits. Historic withdrawals of groundwater since 1906 for public water supply and irrigation have caused major declines in the water levels. The average water level decline in the Hueco Bolson from 1903 to 1980 is approximately 53 feet (White, 1987).

Locally, recharge to the aquifer occurs due to mountain front infiltration of precipitation from the surface and from the injection of treated sewage into the aquifer from the Hueco Bolson Recharge Project (White and Sladek, 1990). Numerous injection wells were constructed northeast of El Paso and water from the Fred Hervey Water Treatment Plant has been injected into the aquifer by El Paso Water Utilities (EPWU) since the mid-1980s. Since 1991, EPWU has been selling water to El Paso Electric Company for use as cooling water at the Newman Plant, thus less water has been injected into the aquifer (Sperka, 1993).

Based on available information, regional groundwater flow direction in the McCombs Landfill area is to the south-southeast. Groundwater movement in the area is generally less than 1.0 feet per day (White, 1987). EPWU groundwater data indicate that the static groundwater elevation in the area is between 3,670 and 3,675 feet MSL or approximately 370 to 390 feet below ground surface (EPWU, 1993).

Groundwater conditions at the site were determined using data from three groundwater monitoring wells constructed in 2003 around the landfill as part of the approved Subtitle D groundwater monitoring system. Water levels data from December 6, 2010 indicates ground water beneath the site occur approximately 390 to 398 feet below land surface, with corresponding elevations of 3,677 to 3,686 feet AMSI. Based on groundwater level measurements at the site, groundwater flow direction is S70º East or to the east-southeast. The site-specific groundwater flow direction correlates with regional groundwater flow direction within the Hueco Bolson aquifer.

Depth to groundwater in the area of McCombs Landfill is approximately 380 to 400 feet below ground surface. The Hueco Bolson aquifer generally contains fresh water in it upper portion and becomes saline at depth (Davis and Leggat, 1965). The Hueco Bolson aquifer is over 200 meters thick (USGS 2003).

MultiMed Computer Model

MultiMed is groundwater fate and transport moded developed for the United States Environmental Protection Agency (US EPA) to assist in the evaluation of alternative landfill liner designs for Subtitle D landfills.

For this alternative liner design, MultiMed is used to evaluate the impact of landfill leachate seepage containing trichloroethylene (TCE) on groundwater at the point of compliance, approximately 30 feet or 10 meters from the waste limit boundary. The model can be run with seepage through the landfill liner system and the unsaturated zone to the water table, or, the model can be run as a saturated zone model only, evaluating seepage directly to the groundwater. This evaluation was run in both modes (saturated and unsaturated/saturated modes) and results compared.

Parameters may be input into the MultiMed model to reflect the site geology and hydrogeologic properties. The model is divided into seven parameter groups for data input:

- General parameters;
- Source parameters;
- Chemical parameters;
- Unsaturated zone flow parameters;
- Unsaturated zone transport parameters;
- Saturated zone parameters; and
- Well location and time parameters.

The following section documents the input parameters used within this model and the information source and/or assumptions used in this evaluation.

MutilMed Model Data

General Parameters

- Application Type - Subtitle D landfills.
- Run Type – The model was run in deterministic mode in which each parameter was assigned a unique value in accordance with the site conditions.
- Source Type – assumed continual steady state flux.
- Aquifer Source Plan Geometry – Gaussian: Treated as enriched along the center line, tapering to each side as in a Gaussian distribution.
- Active Modules – this was run in both Saturated Zone only and Unsaturated & Saturated Zone modules.

Source Parameters

- Source Area – The source area evaluated was the proposed Section B waste disposal cell. This cell is 217.7 acres in area or 881,000 square meters. Since a source area was defined, the source length and wide was derived by the model.
- Source Infiltration Rate – This rate is generated from Hydrologic Evaluation of Landfill Performance (HELP) model completed for the landfill alternative liner design. The infiltration rate was taken as the seepage through both the HDPE synthetic liner and the GCL or the leakage through the composite liner system into the subsurface. The value used for this model was from an open landfill cell with

10 feet of waste in place and no cover system. The leakage rate for the liner was the peak daily average of 0.000015 inches per day*acre or 0.000139 meters per year (m/y). [0.000015 in/d * 0.025 m/in * 365d/y = 1.39E-4 m/y]

- Outside Recharge Rate – The outside recharge rate can also be derived from the HELP model. Given the arid environment of the El Paso area, the recharge rate was assumed to be near zero and a value of 1E-10 meters per year was used.
- Initial Concentration – This model, per TCEQ direction, was run only for the chemical trichloroethylene (TCE) at an assumed initial concentration of 1.3 milligrams per liter (mg/l).
- Initial Spread of Source – this is derived by the MultiMed model.

Chemical Parameters

- Per TCEQ direction, trichloroethylene (TCE) was the only chemical evaluated with for this alternative liner design.
- Normalized Distribution Coefficient (Koc) – assumed to be zero (0.00) Dissolved Decay Coefficient – Derived by MultiMed Model.
- Sorbed Decay Coefficient – Derived by MultiMed Model.
- Overall Aquifer Decay Coefficient – Derived by MultiMed Model.
- Acid Hydrolysis Rate – Hydrolysis was assumed to be zero (0.00) or negligible since it is unlikely trichloroethylene would not undergo much hydrolysis unless the environment was very basic or acidic.
- Neutral Hydrolysis Rate – assumed to be zero (0.00).
- Base Hydrolysis Rate – assumed to be zero (0.00).
- Hydrolysis Reference Temperature – model default of 25 C.
- Aquifer Distribution Coefficient – Derived by MultiMed Model.

Unsaturated Zone Flow

- Selected Flow Layer – One (1) was selected as the unconsolidated deposits beneath the landfill were assumed to one layer of sand.
- Flow Layer Thickness – The flow layer thickness value used was 100 meters. The thickness of unsaturated deposits beneath the lowest landfill liner base elevation (4,022 feet NGVD) and the water table (3,686 feet NGVD (336 feet or 102.4 meters)).
- Saturated Hydraulic Conductivity – 36 cm/hr ($1E10^{-2}$ cm/sec) "Site Characterization and Monitoring Plan, McCombs Landfill, El Paso, Texas", prepared by PSC-The Carel Corporation and dated October 11, 1993, Revised: December 2012; Section 4.7.3 Groundwater Flow Gradient and Rate, pg 16-17. A copy of this document is provided in Appendix 3K, Attachment 1 (pages 20-21) of the Permit Modification, McCombs Landfill – MSW 729B.
- Effective Porosity – 0.30 "Site Characterization and Monitoring Plan, McCombs Landfill, El Paso, Texas", prepared by PSC-The Carel Corporation and dated

October 11, 1993, Revised: December 2012; Section 4.7.3 Groundwater Flow Gradient and Rate, pg 16-17. A copy of this document is provided in Appendix 3K, Attachment 1 (pages 20-21) of the Permit Modification, McCombs Landfill – MSW 729B.

- Air Entry Pressure Head – Assumed to be zero (0.0); this value is typically zero for coarser soils. (Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993).
- Residual Water Content – Default value for sand (0.43). Table D - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993;
- vanGenuchten Alpha – Default value for sand (0.145). Table E - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993;
- vanGenuchten Beta – Default value for sand (2.68). Table E - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.

Unsaturated Zone Transport

- Select Transport Layer – Corresponds to Layer 1 of Unsaturated Zone Flow.
- Transport Layer Thickness - Corresponds to Layer 1 of Unsaturated Zone Flow.
- Longitudinal Dispersivity – Derived MultiMed Model.
- Percentage Organic Matter – assumed to be zero (0.00).
- Bulk Density – Default value for coarse sand (1.69). Table G - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.
- Biological Decay Coefficient – Assumed to be zero, i.e. no biological degradation is occurring in the unsaturated zone.

Saturated Zone

- Aquifer thickness – Hueco Bolson aquifer is over 200 meters thick. For this model, an aquifer thickness of ~~50~~ ***100*** meters was used.
- Mixing Zone Thickness – Derived by MultiMed Model.
- Effective Porosity – 0.30 "Site Characterization and Monitoring Plan, McCombs Landfill, El Paso, Texas", prepared by PSC-The Carel Corporation and dated October 11, 1993, Revised: December 2012; Section 4.7.3 Groundwater Flow Gradient and Rate, pg 16-17. A copy of this document is provided in Appendix 3K, Attachment 1 (pages 20-21) of the Permit Modification, McCombs Landfill – MSW 729B.
- Particle Diameter – Derived by MultiMed Model.
- Bulk Density – Default value for coarse sand (1.69). Table G - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.
- Saturated Hydraulic Conductivity – 3,154 m/y ($1E10^{-2}$ cm/sec) "Site Characterization and Monitoring Plan, McCombs Landfill, El Paso, Texas", prepared by PSC-The Carel Corporation and dated October 11, 1993, Revised: December 2012; Section 4.7.3 Groundwater Flow Gradient and Rate, pg 16-17. A

copy of this document is provided in Appendix 3K, Attachment 1 (pages 20-21) of the Permit Modification, McCombs Landfill – MSW 729B.

- Hydraulic Gradient – 0.0042 "Site Characterization and Monitoring Plan, McCombs Landfill, El Paso, Texas", prepared by PSC-The Carel Corporation and dated October 11, 1993, Revised: December 2012; Section 4.7.3 Groundwater Flow Gradient and Rate, pg 16-17. A copy of this document is provided in Appendix 3K, Attachment 1 (pages 20-21) of the Permit Modification, McCombs Landfill – MSW 729B.
- Seepage Velocity – Derived by MultiMed Model.
- Longitudinal Dispersivity – Derived by MultiMed Model.
- Transverse Dispersivity – Derived by MultiMed Model.
- Aquifer Temperature – Assumed 11°C.
- Aquifer pH – Assumed 7.2 standard pH units.
- Fraction Organic Carbon (foc) – assumed to be zero (0.00).
- Aquifer Retardation Factor – Derived by MultiMed Model.
- Aquifer Biological Decay Rate – No biological decay rate modeled.

Well Location and Time

- Radial Distance to Well – Point of Compliance is approximately 30 feet (10 meters) from waste limit boundary.
- Angle off Plume Axis – For Subtitle D application Angle off Plume Axis is fixed at zero.
- Well Screen Fraction – For Subtitle D application Angle off Plume Axis is fixed at zero.

Summary and Conclusion

The MultiMed model was run under the parameters and assumptions listed in the preceding section and in both the active model for unsaturated zone and saturated zone and with no retardation or degradation. The results of the SATURATED & UNSATURATED versus the SATURATED ONLY model runs differ in the predicted concentration. The predicted concentration of trichloroethylene at the point of compliance, a monitoring point 10 meters directly downgradient of the waste limit boundary for the SATURATED & UNSATURATED model run is 3.365E-04 mg/l (0.000365 mg/l). The SATURATED ONLY model run has a predicted concentration at the point of compliance of 1.535E-04 mg/l (0.0001535 mg.l). The SATURATED ONLY model result (0.0001535 mg/l) is below the established standard, US EPA maximum contaminant level (MCL) of 0.005 mg/l. Both model runs are below the US EPA MCL of 0.005 mg/l.

Based on the results of the MultiMed Model runs, the alternative liner proposed for the McCombs Landfill will meet the requirements of 30 TAC §330.331.

SAIC®

Appendix 3J, Attachment ~~12~~
MultiMed Groundwater Fate and Transport Model for Alternative Landfill Liner Design

Introduction

SAIC, on behalf of the City of El Paso, Texas has prepared a permit ***amendment*** ~~modification~~ for the vertical expansion of the McCombs Landfill. This vertical expansion within the currently permitted landfill footprint will increase the ultimate waste disposal capacity of the Landfill. In addition to the permit ***amendment*** ~~modification~~ for a vertical expansion, SAIC is proposing an alternative liner design utilizing a geocomposite liner (GCL) liner system. The Multimedia Exposure Assessment (MultiMed) model was completed as part of the alternative liner design to evaluate the potential impacts to groundwater associated with the landfill development and the alternative liner design and to ensure compliance with the contituents listed within Table 1 of 30 TAC §330.331.

Landfill Liner

The McCombs Landfill currently uses an alternative liner design that was approved on July 10, 1995. The approved liner (referenced as "Scenaro 1") consists of (from bottom to top), 6-inches of compacted subgrade, 6-inches of caliche, 60-mil high density polyethylene (HDPE) geomembrane liner and 24-inches protective soil cover.

The proposed alternative liner design (referred to as"Scenaro 2") for the McCombs Landfill is as follows (from bottom to top):

- 6-inch compacted subgrade;
- GCL;
- 60-mil HDPE geomembrane liner;
- 24-inch protective cover; and
- Waste.

Based on the results of the HELP modeling, the combination of HDPE geomembrane liner with GCL provides a ***lower permeability*** ~~less permeable~~ barrier system ***with a leakage rate through the modeled barrier system subgrade*** ~~***(layer 7 in the attached HELP model report)***~~ ***of 0.000015 inch per day (in/d) or 1.39E-04 meters per year (m/y).*** *[0.000015 in/d *0.0254m/in * 365d/y =0.000139 m/y].* ~~***Peak daily values for percolation through layer 6 (modeled as the GCL layer in the attached HELP model report) was 0.000002 in/d or 1.854E-05 m/y, however, the value of 1.39E-04 m/y was used as a more conservative value.***~~ ~~than the currently designed geomembrane and compacted caliche composite liner system~~.

The HELP model was run to evaluate several scenarios as part of the alternative liner approval and copies of the HELP model runs are provided in Appendix 3I, Attachment

1. Based the on various scenarios, HELP model runs were completed for this permit amendment. The peak daily percolation/leakage value predicted through the GCL subgrade layer of the alternative liner design for each scenario is 0.000015 inch, as depicted in the table below.

Site Geology and Hydrogeology

The McCombs Landfill is located on deposits of the Hueco Bolson, probably Camp Rice Formation. These deposits primarily consist of clay, sand, and gravel, with some caliche. The landfill site is underlain by Tertiary and Quaternary basin (Bolson) deposits, overlain by areas of gravel and caliche rimrock. Recent Quaternary alluvial deposits are also present in the Landfill vicinity in topographically low areas.

Boring logs for wells drilled on site to depths greater than 500 feet generally indicate deposits of:

- 0 – 50 feet Sand, and sand and gravel;
- 50-250 feet Sand, with some clay;
- 250-470 feet Sand and fine gravel mix; and
- 470-560 feet Sandy clay.

In general, the relatively clean sands are non-plastic, while sandy clay ranges from low to high plasticity. Permeability tests were not considered necessary based on the soil

types encountered during the site characterization. Estimated coefficients of permeability are between 0.01 and 0.04 centimeters per second.

The regional groundwater system in the area primarily consists of the Hueco Bolson aquifers. The Hueco Bolson is divided into the City Artesian area, the Mesa area and the Lower Valley (Leggart, 1962). The Mesa area extends north of the City Artesian area into New Mexico and east to the Hueco Mountains. The Landfill is located within the Mesa area.

Two aquifers occur in these areas: an upper aquifer in the Rio Grande alluvium and a lower aquifer in the Hueco Bolson deposits. Since no known impermeable zone of regional extent separates these aquifers, the Rio Grande alluvium and the Hueco Bolson are considered to be, at least in part, hydrologically connected in the City Artesian and Lower Valley areas (Alvared and Buckner, 1980). The Mesa area primarily consists of Hueco Bolson deposits. Historic withdrawals of groundwater since 1906 for public water supply and irrigation have caused major declines in the water levels. The average water level decline in the Hueco Bolson from 1903 to 1980 is approximately 53 feet (White, 1987).

Locally, recharge to the aquifer occurs due to mountain front infiltration of precipitation from the surface and from the injection of treated sewage into the aquifer from the Hueco Bolson Recharge Project (White and Sladek, 1990). Numerous injection wells were constructed northeast of El Paso and water from the Fred Hervey Water Treatment Plant has been injected into the aquifer by El Paso Water Utilities (EPWU) since the mid-1980s. Since 1991, EPWU has been selling water to El Paso Electric Company for use as cooling water at the Newman Plant, thus less water has been injected into the aquifer (Sperka, 1993).

Based on available information, regional groundwater flow direction in the McCombs Landfill area is to the south-southeast. Groundwater movement in the area is generally less than 1.0 feet per day (White, 1987). EPWU groundwater data indicate that the static groundwater elevation in the area is between 3,670 and 3,675 feet MSL or approximately 370 to 390 feet below ground surface (EPWU, 1993).

Groundwater conditions at the site were determined using data from three groundwater monitoring wells constructed in 2003 around the landfill as part of the approved Subtitle D groundwater monitoring system. Water levels data from December 6, 2010 indicates ground water beneath the site occur approximately 390 to 398 feet below land surface, with corresponding elevations of 3,677 to 3,686 feet AMSI. Based on groundwater level measurements at the site, groundwater flow direction is S70º East or to the east-southeast. The site-specific groundwater flow direction correlates with regional groundwater flow direction within the Hueco Bolson aquifer.

Depth to groundwater in the area of McCombs Landfill is approximately 380 to 400 feet below ground surface. The Hueco Bolson aquifer generally contains fresh water in it upper portion and becomes saline at depth (Davis and Leggat, 1965). The Hueco Bolson aquifer is over 200 meters thick (USGS 2003).

MultiMed Computer Model

MultiMed is groundwater fate and transport moded developed for the United States Environmental Protection Agency (US EPA) to assist in the evaluation of alternative landfill liner designs for Subtitle D landfills.

For this alternative liner design, MultiMed is used to evaluate the impact of landfill leachate seepage containing trichloroethylene (TCE) on groundwater at the point of compliance, ~~125~~ ***approximately 30*** feet ***or 10 meters*** from the waste limit boundary. The model can be run with seepage through the landfill liner system and the unsaturated zone to the water table, or, the model can be run as a saturated zone model only, evaluating seepage directly to the groundwater. ~~This evaluation was run in both modes and compared. ***The MultiMed computer model was run to reflect the subsurface conditions beneath the landfill.***~~ *This evaluation was run in both modes (saturated and unsaturated/saturated modes) and results compared.*

Parameters may be input into the MultiMed model to reflect the site geology and hydrogeologic properties. The model is divided into seven parameter groups for data input:

- General parameters;
- Source parameters;
- Chemical parameters;
- Unsaturated zone flow parameters;
- Unsaturated zone transport parameters;
- Saturated zone parameters; and
- Well location and time parameters.

The following section documents the input parameters used within this model and the information source and/or assumptions used in this evaluation.

MutilMed Model Data

General Parameters

- Application Type - Subtitle D landfills.
- Run Type – The model was run in deterministic mode in which each parameter was assigned a unique value in accordance with the site conditions.
- Source Type – assumed continual steady state flux.
- Aquifer Source Plan Geometry – Gaussian: Treated as enriched along the center line, tapering to each side as in a Gaussian distribution.
- Active Modules – this was run in both Saturated Zone only and Unsaturated & Saturated Zone modules.

Source Parameters

- Source Area – The source area evaluated was the proposed Section B waste disposal cell. This cell is ~~22.61~~ ***217.7*** acres in area or ~~91,500~~ ***881,000*** square meters. Since a source area was defined, the source length and wide was derived by the model.
- Source Infiltration Rate – This rate is generated from Hydrologic Evaluation of Landfill Performance (HELP) model completed for the landfill alternative liner design. The infiltration rate was taken as the seepage through both the HDPE synthetic liner and the GCL or the leakage through the composite liner system into the subsurface. The value used for this model was from an open landfill cell with 10 feet of waste in place and no cover system. The leakage rate for the liner was the peak daily average of 0.000015 inches per day*acre or ~~0.000314~~ ***0.000139*** meters per year (m/y). ***[0.000015 in/d * 0.025 m/in * 365d/y = 1.39E-4 m/y]***
- Outside Recharge Rate – The outside recharge rate can also be derived from the HELP model. Given the arid environment of the El Paso area, the recharge rate was assumed to be near zero and a value of 1E-10 meters per year was used.
- Initial Concentration – This model, per TCEQ direction, was run only for the chemical trichloroethylene (TCE) at an assumed initial concentration of 1.3 milligrams per liter (mg/l).
- Initial Spread of Source – this is derived by the MultiMed model.

Chemical Parameters

- Per TCEQ direction, trichloroethylene (TCE) was the only chemical evaluated with for this alternative liner design.
- Normalized Distribution Coefficient (Koc) – ***assumed to be zero (0.00)*** ~~The Koc is used to estimate the contaminant distribution coefficient for the unsaturated zone. This value, 152, was taken from Table 10.5 of Applied Hydrogeology, second edition (Fetter, C.W.), the Koc for trichloroethylene.~~
- Dissolved Decay Coefficient – Derived by MultiMed Model.
- Sorbed Decay Coefficient – Derived by MultiMed Model.
- Overall Aquifer Decay Coefficient – Derived by MultiMed Model.
- Acid Hydrolysis Rate – Hydrolysis was assumed to be zero (0.00) or negligible since it is unlikely trichloroethylene would not undergo much hydrolysis unless the environment was very basic or acidic.
- Neutral Hydrolysis Rate – assumed to be zero (0.00).
- Base Hydrolysis Rate – assumed to be zero (0.00).
- Hydrolysis Reference Temperature – model default of 25 C.
- Aquifer Distribution Coefficient – Derived by MultiMed Model.

Unsaturated Zone Flow

- Selected Flow Layer – One (1) was selected as the unconsolidated deposits beneath the landfill were assumed to one layer of sand.
- Flow Layer Thickness – The flow layer thickness value used was 100 meters. The thickness of unsaturated deposits beneath the lowest landfill liner base elevation (4,022 feet NGVD) and the water table (3,686 feet NGVD (336 feet or 102.4 meters)).
- Saturated Hydraulic Conductivity – *36 cm/hr (1E10^{-2} cm/sec) "Site Characterization and Monitoring Plan, McCombs Landfill, El Paso, Texas", prepared by PSC-The Carel Corporation and dated October 11, 1993, Revised: December 2012; Section 4.7.3 Groundwater Flow Gradient and Rate, pg 16-17. A copy of this document is provided in Appendix 3K, Attachment 1 (pages 20-21) of the Permit Modification, McCombs Landfill – MSW 729B.* ~~***3.6 cm/hr was selected based on descriptions of actual site condictions.*** Default value for sand (29.7 cm/hr). Table B - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.~~
- Effective Porosity – *0.30 "Site Characterization and Monitoring Plan, McCombs Landfill, El Paso, Texas", prepared by PSC-The Carel Corporation and dated October 11, 1993, Revised: December 2012; Section 4.7.3 Groundwater Flow Gradient and Rate, pg 16-17. A copy of this document is provided in Appendix 3K, Attachment 1 (pages 20-21) of the Permit Modification, McCombs Landfill – MSW 729B.* ~~Default value for coarse sand (0.38). Table C - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.~~
- Air Entry Pressure Head – Assumed to be zero (0.0); this value is typically zero for coarser soils. (Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993).
- Residual Water Content – Default value for sand (0.43). Table D - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993;
- vanGenuchten Alpha – Default value for sand (0.145). Table E - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993;
- vanGenuchten Beta – Default value for sand (2.68). Table E - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.

Unsaturated Zone Transport

- Select Transport Layer – Corresponds to Layer 1 of Unsaturated Zone Flow.
- Transport Layer Thickness - Corresponds to Layer 1 of Unsaturated Zone Flow.
- Longitudinal Dispersivity – Derived MultiMed Model.
- Percentage Organic Matter – ***assumed to be zero (0.00)*** ~~Default value for Group A: deep sand (0.11). Table K - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.~~
- Bulk Density – Default value for coarse sand (1.69). Table G - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.

- Biological Decay Coefficient – Assumed to be zero, i.e. no biological degradation is occurring in the unsaturated zone.

Saturated Zone

- Aquifer thickness – Hueco Bolson aquifer is over 200 meters thick. For this model, an aquifer thickness of ~~50~~ ***100*** meters was used.
- Mixing Zone Thickness – Derived by MultiMed Model.
- Effective Porosity – *0.30 "Site Characterization and Monitoring Plan, McCombs Landfill, El Paso, Texas", prepared by PSC-The Carel Corporation and dated October 11, 1993, Revised: December 2012; Section 4.7.3 Groundwater Flow Gradient and Rate, pg 16-17. A copy of this document is provided in Appendix 3K, Attachment 1 (pages 20-21) of the Permit Modification, McCombs Landfill – MSW 729B.* ~~***Derived by MultiMed Model basedon particle diameter.*** This value (0.30) was data provided in: Permit Modification, McCombs Landfill – MSW 729A, Groundwater Monitoring System, Task 5, Submittal, prepared by Parkhill, Smith and Cooper and dated July 2009.~~
- ***Particle Diameter –*** *Derived by MultiMed Model* ***.*** ~~***0.025 cm based on the site characterization study completed in 1987.***~~
- Bulk Density – Default value for coarse sand (1.69). Table G - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.
- Saturated Hydraulic Conductivity – *3,154 m/y (1E10^{-2} cm/sec) "Site Characterization and Monitoring Plan, McCombs Landfill, El Paso, Texas", prepared by PSC-The Carel Corporation and dated October 11, 1993, Revised: December 2012; Section 4.7.3 Groundwater Flow Gradient and Rate, pg 16-17. A copy of this document is provided in Appendix 3K, Attachment 1 (pages 20-21) of the Permit Modification, McCombs Landfill – MSW 729B.* ~~This value (6,307 m/y) was data provided in: Permit Modification, McCombs Landfill – MSW 729A, Groundwater Monitoring System, Task 5, Submittal, prepared by Parkhill, Smith and Cooper and dated July 2009.~~
- Hydraulic Gradient – *0.0042 "Site Characterization and Monitoring Plan, McCombs Landfill, El Paso, Texas", prepared by PSC-The Carel Corporation and dated October 11, 1993, Revised: December 2012; Section 4.7.3 Groundwater Flow Gradient and Rate, pg 16-17. A copy of this document is provided in Appendix 3K, Attachment 1 (pages 20-21) of the Permit Modification, McCombs Landfill – MSW 729B.* ~~This value (0.0042) was data provided in: Permit Modification, McCombs Landfill – MSW 729A, Groundwater Monitoring System, Task 5, Submittal, prepared by Parkhill, Smith and Cooper and dated July 2009.~~
- Seepage Velocity – Derived by MultiMed Model.
- Longitudinal Dispersivity – Derived by MultiMed Model.
- Transverse Dispersivity – Derived by MultiMed Model.
- Aquifer Temperature – Assumed 11°C.
- Aquifer pH – Assumed 7.2 standard pH units.

- Fraction Organic Carbon (foc) – ***assumed to be zero (0.00)*** ~~Calculated: foc = OM% / (100 x 1.72); foc =11% / (100 x 1.72)~~.
- Aquifer Retardation Factor – Derived by MultiMed Model.
- Aquifer Biological Decay Rate – No biological decay rate modeled.

Well Location and Time

- Radial Distance to Well – Point of Compliance is ~~125~~ ***approximately 30*** feet (~~38~~ ***10*** meters) from waste limit boundary.
- Angle off Plume Axis – For Subtitle D application Angle off Plume Axis is fixed at zero.
- Well Screen Fraction – For Subtitle D application Angle off Plume Axis is fixed at zero.

Summary and Conclusion

The MultiMed model was run under the parameters and assumptions listed in the preceding section and in both the active model for unsaturated zone and saturated zone *and with no* retardation or degradation. ~~Therefore, the results for both modes are the same, showing no retardation or degradation in the unsaturated zone.~~ *The results of the SATURATED & UNSATURATED versus the SATURATED ONLY model runs differ in the predicted concentration.* The predicted concentration of trichloroethylene at the point of compliance, ~~is~~ ~~0.003412~~ ***0.0001532*** ~~mg/l~~, a monitoring point ~~125 feet~~ ***10 meters*** directly downgradient of the waste limit boundary *for the SATURATED & UNSATURATED model run is 3.365E-04 mg/l (0.000365 mg/l). The SATURATED ONLY model run has a predicted concentration at the point of compliance of 1.535E-04 mg/l (0.0001535 mg.l).* ~~If the model is run with the point of compliance set at one meter from the waste limit boundary, the predicted concentration for TCE is 0.003475 mg/l. Both~~ ***The*** *SATURATED ONLY model* result~~s~~ *(0.0001535 mg/l)* ~~are~~ ***is*** below the established standard, US EPA maximum contaminant level (MCL) of 0.005 mg/l. *Both model runs are below the US EPA MCL of 0.005 mg/l.*

Based on the results of the MultiMed Model runs, the alternative liner proposed for the McCombs Landfill will meet the requirements of 30 TAC §330.331.

Appendix 3J, Attachment *12*
MultiMed Groundwater Fate and Transport Model for Alternative Landfill Liner Design

Introduction

SAIC, on behalf of the City of El Paso, Texas has prepared a permit ***amendment*** ~~modification~~ for the vertical expansion of the McCombs Landfill. This vertical expansion within the currently permitted landfill footprint will increase the ultimate waste disposal capacity of the Landfill. In addition to the permit ***amendment*** ~~modification~~ for a vertical expansion, SAIC is proposing an alternative liner design utilizing a geocomposite liner (GCL) liner system. The Multimedia Exposure Assessment (MultiMed) model was completed as part of the alternative liner design to evaluate the potential impacts to groundwater associated with the landfill development and the alternative liner design and to ensure compliance with the contituents listed within Table 1 of 30 TAC §330.331.

Landfill Liner

The McCombs Landfill currently uses an alternative liner design that was approved on July 10, 1995. The approved liner (referenced as "Scenaro 1") consists of (from bottom to top), 6-inches of compacted subgrade, 6-inches of caliche, 60-mil high density polyethylene (HDPE) geomembrane liner and 24-inches protective soil cover.

The proposed alternative liner design (referred to as"Scenaro 2") for the McCombs Landfill is as follows (from bottom to top):

- 6-inch compacted subgrade;
- GCL;
- 60-mil HDPE geomembrane liner;
- 24-inch protective cover; and
- Waste.

Based on the results of the HELP modeling, the combination of HDPE geomembrane liner with GCL provides a ***lower permeability*** ~~less permeable~~ barrier system ***with a leakage rate through the modeled barrier system subgrade (layer 7 in the attached HELP model report) of 0.000015 inch per day (in/d) or 1.39E-04 meters per year (m/y). Peak daily values for percolation through layer 6 (modeled as the GCL layer in the attached HELP model report) was 0.000002 in/d or 1.854E-05 m/y, however, the value of 1.39E-04 m/y was used as a more conservative value.*** ~~than the currently designed geomembrane and compacted caliche composite liner system~~.

Site Geology and Hydrogeology

The McCombs Landfill is located on deposits of the Hueco Bolson, probably Camp Rice Formation. These deposits primarily consist of clay, sand, and gravel, with some caliche. The landfill site is underlain by Tertiary and Quaternary basin (Bolson) deposits, overlain by areas of gravel and caliche rimrock. Recent Quaternary alluvial deposits are also present in the Landfill vicinity in topographically low areas.

Boring logs for wells drilled on site to depths greater than 500 feet generally indicate deposits of:

- 0 – 50 feet Sand, and sand and gravel;
- 50-250 feet Sand, with some clay;
- 250-470 feet Sand and fine gravel mix; and
- 470-560 feet Sandy clay.

In general, the relatively clean sands are non-plastic, while sandy clay ranges from low to high plasticity. Permeability tests were not considered necessary based on the soil types encountered during the site characterization. Estimated coefficients of permeability are between 0.01 and 0.04 centimeters per second.

The regional groundwater system in the area primarily consists of the Hueco Bolson aquifers. The Hueco Bolson is divided into the City Artesian area, the Mesa area and the Lower Valley (Leggart, 1962). The Mesa area extends north of the City Artesian area into New Mexico and east to the Hueco Mountains. The Landfill is located within the Mesa area.

Two aquifers occur in these areas: an upper aquifer in the Rio Grande alluvium and a lower aquifer in the Hueco Bolson deposits. Since no known impermeable zone of regional extent separates these aquifers, the Rio Grande alluvium and the Hueco Bolson are considered to be, at least in part, hydrologically connected in the City Artesian and Lower Valley areas (Alvared and Buckner, 1980). The Mesa area primarily consists of Hueco Bolson deposits. Historic withdrawals of groundwater since 1906 for public water supply and irrigation have caused major declines in the water levels. The average water level decline in the Hueco Bolson from 1903 to 1980 is approximately 53 feet (White, 1987).

Locally, recharge to the aquifer occurs due to mountain front infiltration of precipitation from the surface and from the injection of treated sewage into the aquifer from the Hueco Bolson Recharge Project (White and Sladek, 1990). Numerous injection wells were constructed northeast of El Paso and water from the Fred Hervey Water Treatment Plant has been injected into the aquifer by El Paso Water Utilities (EPWU) since the mid-1980s. Since 1991, EPWU has been selling water to El Paso Electric Company for use as cooling water at the Newman Plant, thus less water has been injected into the aquifer (Sperka, 1993).

Based on available information, regional groundwater flow direction in the McCombs Landfill area is to the south-southeast. Groundwater movement in the area is generally less than 1.0 feet per day (White, 1987). EPWU groundwater data indicate

that the static groundwater elevation in the area is between 3,670 and 3,675 feet MSL or approximately 370 to 390 feet below ground surface (EPWU, 1993).

Groundwater conditions at the site were determined using data from three groundwater monitoring wells constructed in 2003 around the landfill as part of the approved Subtitle D groundwater monitoring system. Water levels data from December 6, 2010 indicates ground water beneath the site occur approximately 390 to 398 feet below land surface, with corresponding elevations of 3,677 to 3,686 feet AMSI. Based on groundwater level measurements at the site, groundwater flow direction is S70º East or to the east-southeast. The site-specific groundwater flow direction correlates with regional groundwater flow direction within the Hueco Bolson aquifer.

Depth to groundwater in the area of McCombs Landfill is approximately 380 to 400 feet below ground surface. The Hueco Bolson aquifer generally contains fresh water in it upper portion and becomes saline at depth (Davis and Leggat, 1965). The Hueco Bolson aquifer is over 200 meters thick (USGS 2003).

MultiMed Computer Model

MultiMed is groundwater fate and transport moded developed for the United States Environmental Protection Agency (US EPA) to assist in the evaluation of alternative landfill liner designs for Subtitle D landfills.

For this alternative liner design, MultiMed is used to evaluate the impact of landfill leachate seepage containing trichloroethylene (TCE) on groundwater at the point of compliance, ~~125~~ ***approximately 30*** feet ***or 10 meters*** from the waste limit boundary. The model can be run with seepage through the landfill liner system and the unsaturated zone to the water table, or, the model can be run as a saturated zone model only, evaluating seepage directly to the groundwater. ~~This evaluation was run in both modes and compared.~~ ***The MultiMed computer model was run to reflect the subsurface conditions beneath the landfill.***

Parameters may be input into the MultiMed model to reflect the site geology and hydrogeologic properties. The model is divided into seven parameter groups for data input:

- General parameters;
- Source parameters;
- Chemical parameters;
- Unsaturated zone flow parameters;
- Unsaturated zone transport parameters;
- Saturated zone parameters; and
- Well location and time parameters.

The following section documents the input parameters used within this model and the information source and/or assumptions used in this evaluation.

MutilMed Model Data

General Parameters

- Application Type - Subtitle D landfills.
- Run Type – The model was run in deterministic mode in which each parameter was assigned a unique value in accordance with the site conditions.
- Source Type – assumed continual steady state flux.
- Aquifer Source Plan Geometry – Gaussian: Treated as enriched along the center line, tapering to each side as in a Gaussian distribution.
- Active Modules – this was run in both Saturated Zone only and Unsaturated & Saturated Zone modules.

Source Parameters

- Source Area – The source area evaluated was the proposed Section B waste disposal cell. This cell is ~~22.61~~ ***217.7*** acres in area or ~~91,500~~ ***881,000*** square meters. Since a source area was defined, the source length and wide was derived by the model.
- Source Infiltration Rate – This rate is generated from Hydrologic Evaluation of Landfill Performance (HELP) model completed for the landfill alternative liner design. The infiltration rate was taken as the seepage through both the HDPE synthetic liner and the GCL or the leakage through the composite liner system into the subsurface. The value used for this model was from an open landfill cell with 10 feet of waste in place and no cover system. The leakage rate for the liner was the peak daily average of 0.000015 inches per day*acre or ~~0.000314~~ ***0.000139*** meters per year (m/y). ***[0.000015 in/d * 0.025 m/in * 365d/y = 1.39E-4 m/y]***
- Outside Recharge Rate – The outside recharge rate can also be derived from the HELP model. Given the arid environment of the El Paso area, the recharge rate was assumed to be near zero and a value of 1E-10 meters per year was used.
- Initial Concentration – This model, per TCEQ direction, was run only for the chemical trichloroethylene (TCE) at an assumed initial concentration of 1.3 milligrams per liter (mg/l).
- Initial Spread of Source – this is derived by the MultiMed model.

Chemical Parameters

- Per TCEQ direction, trichloroethylene (TCE) was the only chemical evaluated with for this alternative liner design.
- Normalized Distribution Coefficient (Koc) – ***assumed to be zero (0.00)*** ~~The Koc is used to estimate the contaminant distribution coefficient for the unsaturated zone. This value, 152, was taken from Table 10.5 of Applied Hydrogeology, second edition (Fetter, C.W.), the Koc for trichloroethylene.~~
- Dissolved Decay Coefficient – Derived by MultiMed Model.
- Sorbed Decay Coefficient – Derived by MultiMed Model.

- Overall Aquifer Decay Coefficient – Derived by MultiMed Model.
- Acid Hydrolysis Rate – Hydrolysis was assumed to be zero (0.00) or negligible since it is unlikely trichloroethylene would not undergo much hydrolysis unless the environment was very basic or acidic.
- Neutral Hydrolysis Rate – assumed to be zero (0.00).
- Base Hydrolysis Rate – assumed to be zero (0.00).
- Hydrolysis Reference Temperature – model default of 25 C.
- Aquifer Distribution Coefficient – Derived by MultiMed Model.

Unsaturated Zone Flow

- Selected Flow Layer – One (1) was selected as the unconsolidated deposits beneath the landfill were assumed to one layer of sand.
- Flow Layer Thickness – The flow layer thickness value used was 100 meters. The thickness of unsaturated deposits beneath the lowest landfill liner base elevation (4,022 feet NGVD) and the water table (3,686 feet NGVD (336 feet or 102.4 meters)).
- Saturated Hydraulic Conductivity – ***3.6 cm/hr was selected based on descriptions of actual site condictions.*** ~~Default value for sand (29.7 cm/hr). Table B - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.~~
- Effective Porosity – Default value for coarse sand (0.38). Table C - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.
- Air Entry Pressure Head – Assumed to be zero (0.0); this value is typically zero for coarser soils. (Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993).
- Residual Water Content – Default value for sand (0.43). Table D - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993;
- vanGenuchten Alpha – Default value for sand (0.145). Table E - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993;
- vanGenuchten Beta – Default value for sand (2.68). Table E - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.

Unsaturated Zone Transport

- Select Transport Layer – Corresponds to Layer 1 of Unsaturated Zone Flow.
- Transport Layer Thickness - Corresponds to Layer 1 of Unsaturated Zone Flow.
- Longitudinal Dispersivity – Derived MultiMed Model.
- Percentage Organic Matter – ***assumed to be zero (0.00)*** ~~Default value for Group A: deep sand (0.11). Table K - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.~~
- Bulk Density – Default value for coarse sand (1.69). Table G - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.

- Biological Decay Coefficient – Assumed to be zero, i.e. no biological degradation is occurring in the unsaturated zone.

Saturated Zone

- Aquifer thickness – Hueco Bolson aquifer is over 200 meters thick. For this model, an aquifer thickness of ~~50~~ ***100*** meters was used.
- Mixing Zone Thickness – Derived by MultiMed Model.
- Effective Porosity – ***Derived by MultiMed Model basedon particle diameter.*** ~~This value (0.30) was data provided in: Permit Modification, McCombs Landfill – MSW 729A, Groundwater Monitoring System, Task 5, Submittal, prepared by Parkhill, Smith and Cooper and dated July 2009.~~
- ***Particle Diameter – 0.025 cm based on the site characterization study completed in 1987.***
- Bulk Density – Default value for coarse sand (1.69). Table G - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.
- Saturated Hydraulic Conductivity – This value (6,307 m/y) was data provided in: Permit Modification, McCombs Landfill – MSW 729A, Groundwater Monitoring System, Task 5, Submittal, prepared by Parkhill, Smith and Cooper and dated July 2009.
- Hydraulic Gradient – This value (0.0042) was data provided in: Permit Modification, McCombs Landfill – MSW 729A, Groundwater Monitoring System, Task 5, Submittal, prepared by Parkhill, Smith and Cooper and dated July 2009.
- Seepage Velocity – Derived by MultiMed Model.
- Longitudinal Dispersivity – Derived by MultiMed Model.
- Transverse Dispersivity – Derived by MultiMed Model.
- Aquifer Temperature – Assumed 11°C.
- Aquifer pH – Assumed 7.2 standard pH units.
- Fraction Organic Carbon (foc) – ***assumed to be zero (0.00)*** ~~Calculated: foc = OM% / (100 x 1.72); foc =11% / (100 x 1.72)~~.
- Aquifer Retardation Factor – Derived by MultiMed Model.
- Aquifer Biological Decay Rate – No biological decay rate modeled.

Well Location and Time

- Radial Distance to Well – Point of Compliance is ~~125~~ ***approximately 30*** feet (~~38~~ ***10*** meters) from waste limit boundary.
- Angle off Plume Axis – For Subtitle D application Angle off Plume Axis is fixed at zero.
- Well Screen Fraction – For Subtitle D application Angle off Plume Axis is fixed at zero.

Summary and Conclusion

The MultiMed model was run under the parameters and assumptions listed in the preceding section and in both the active model for unsaturated zone and saturated zone mode. The model parameters reflect a conservative analysis and assume no retardation or degradation. Therefore, the results for both modes are the same, showing no retardation or degradation in the unsaturated zone. The predicted concentration of trichloroethylene at the point of compliance is ~~0.003412~~ ***0.0001532*** mg/l, a monitoring point ~~125 feet~~ ***10 meters*** directly downgradient of the waste limit boundary. ~~If the model is run with the point of compliance set at one meter from the waste limit boundary, the predicted concentration for TCE is 0.003475 mg/l. Both~~ ***The*** result~~s~~ ~~are~~ ***is*** below the established standard, US EPA maximum contaminant level (MCL) of 0.005 mg/l.

Based on the results of the MultiMed Model runs, the alternative liner proposed for the McCombs Landfill will meet the requirements of 30 TAC §330.331.

Boring logs for wells drilled on site to depths greater than 500 feet generally indicate deposits of:

- 0 – 50 feet Sand, and sand and gravel;
- 50-250 feet Sand, with some clay;
- 250-470 feet Sand and fine gravel mix; and
- 470-560 feet Sandy clay.

In general, the relatively clean sands are non-plastic, while sandy clay ranges from low to high plasticity. Permeability tests were not considered necessary based on the soil types encountered during the site characterization. Estimated coefficients of permeability are between 0.01 and 0.04 centimeters per second.

The regional groundwater system in the area primarily consists of the Hueco Bolson aquifers. The Hueco Bolson is divided into the City Artesian area, the Mesa area and the Lower Valley (Leggart, 1962). The Mesa area extends north of the City Artesian area into New Mexico and east to the Hueco Mountains. The Landfill is located within the Mesa area.

Two aquifers occur in these areas: an upper aquifer in the Rio Grande alluvium and a lower aquifer in the Hueco Bolson deposits. Since no known impermeable zone of regional extent separates these aquifers, the Rio Grande alluvium and the Hueco Bolson are considered to be, at least in part, hydrologically connected in the City Artesian and Lower Valley areas (Alvared and Buckner, 1980). The Mesa area primarily consists of Hueco Bolson deposits. Historic withdrawals of groundwater since 1906 for public water supply and irrigation have caused major declines in the water levels. The average water level decline in the Hueco Bolson from 1903 to 1980 is approximately 53 feet (White, 1987).

Locally, recharge to the aquifer occurs due to mountain front infiltration of precipitation from the surface and from the injection of treated sewage into the aquifer from the Hueco Bolson Recharge Project (White and Sladek, 1990). Numerous injection wells were constructed northeast of El Paso and water from the Fred Hervey Water Treatment Plant has been injected into the aquifer by El Paso Water Utilities (EPWU) since the mid-1980s. Since 1991, EPWU has been selling water to El Paso Electric Company for use as cooling water at the Newman Plant, thus less water has been injected into the aquifer (Sperka, 1993).

Based on available information, regional groundwater flow direction in the McCombs Landfill area is to the south-southeast. Groundwater movement in the area is generally less than 1.0 feet per day (White, 1987). EPWU groundwater data indicate that the static groundwater elevation in the area is between 3,670 and 3,675 feet MSL or approximately 370 to 390 feet below ground surface (EPWU, 1993).

Groundwater conditions at the site were determined using data from three groundwater monitoring wells constructed in 2003 around the landfill as part of the approved Subtitle D groundwater monitoring system. Water levels data from December 6, 2010 indicates ground water beneath the site occur approximately 390 to 398 feet below land surface, with corresponding elevations of 3,677 to 3,686 feet AMSI. Based on groundwater level measurements at the site, groundwater flow direction is S70º East

or to the east-southeast. The site-specific groundwater flow direction correlates with regional groundwater flow direction within the Hueco Bolson aquifer.

Depth to groundwater in the area of McCombs Landfill is approximately 380 to 400 feet below ground surface. The Hueco Bolson aquifer generally contains fresh water in it upper portion and becomes saline at depth (Davis and Leggat, 1965). The Hueco Bolson aquifer is over 200 meters thick (USGS 2003).

MultiMed Computer Model

MultiMed is groundwater fate and transport moded developed for the United States Environmental Protection Agency (US EPA) to assist in the evaluation of alternative landfill liner designs for Subtitle D landfills.

For this alternative liner design, MultiMed is used to evaluate the impact of landfill leachate seepage containing trichloroethylene (TCE) on groundwater at the point of compliance, 125 feet from the waste limit boundary. The model can be run with seepage through the landfill liner system and the unsaturated zone to the water table, or, the model can be run as a saturated zone model only, evaluating seepage directly to the groundwater. This evaluation was run in both modes and compared.

Parameters may be input into the MultiMed model to reflect the site geology and hydrogeologic properties. The model is divided into seven parameter groups for data input:

- General parameters;
- Source parameters;
- Chemical parameters;
- Unsaturated zone flow parameters;
- Unsaturated zone transport parameters;
- Saturated zone parameters; and
- Well location and time parameters.

The following section documents the input parameters used within this model and the information source and/or assumptions used in this evaluation.

MutilMed Model Data

General Parameters

- Application Type - Subtitle D landfills.
- Run Type – The model was run in deterministic mode in which each parameter was assigned a unique value in accordance with the site conditions.
- Source Type – assumed continual steady state flux.
- Aquifer Source Plan Geometry – Gaussian: Treated as enriched along the center line, tapering to each side as in a Gaussian distribution.

- Active Modules – this was run in both Saturated Zone only and Unsaturated & Saturated Zone modules.

Source Parameters

- Source Area – The source area evaluated was the proposed Section B waste disposal cell. This cell is 22.61 acres in area or 91,500 square meters. Since a source area was defined, the source length and wide was derived by the model.
- Source Infiltration Rate – This rate is generated from Hydrologic Evaluation of Landfill Performance (HELP) model completed for the landfill alternative liner design. The infiltration rate was taken as the seepage through both the HDPE synthetic liner and the GCL or the leakage through the composite liner system into the subsurface. The value used for this model was from an open landfill cell with 10 feet of waste in place and no cover system. The leakage rate for the liner was the peak daily average fo 0.000015 inches per day*acre or 0.000314 meters per year (m/y).
- Outside Recharge Rate – The outside recharge rate can also be derived from the HELP model. Given the arid environment of the El Paso area, the recharge rate was assumed to be near zero and a value of 1E-10 meters per year was used.
- Initial Concentration – This model, per TCEQ direction, was run only for the chemical trichloroethylene (TCE) at an assumed initial concentration of 1.3 milligrams per liter (mg/l).
- Initial Spread of Source – this is derived by the MultiMed model.

Chemical Parameters

- Per TCEQ direction, trichloroethylene (TCE) was the only chemical evaluated with for this alternative liner design.
- Normalized Distribution Coefficient (Koc) – The Koc is used to estimate the contaminant distribution coefficient for the unsaturated zone. This value, 152, was taken from Table 10.5 of Applied Hydrogeology, second edition (Fetter, C.W.), the Koc for trichloroethylene.
- Dissolved Decay Coefficient – Derived by MultiMed Model.
- Sorbed Decay Coefficient – Derived by MultiMed Model.
- Overall Aquifer Decay Coefficient – Derived by MultiMed Model.
- Acid Hydrolysis Rate – Hydrolysis was assumed to be zero (0.00) or negligible since it is unlikely trichloroethylene would not undergo much hydrolysis unless the environment was very basic or acidic.
- Neutral Hydrolysis Rate – assumed to be zero (0.00).
- Base Hydrolysis Rate – assumed to be zero (0.00).
- Hydrolysis Reference Temperature – model default of 25 C.
- Aquifer Distribution Coefficient – Derived by MultiMed Model.

Unsaturated Zone Flow

- Selected Flow Layer – One (1) was selected as the unconsolidated deposits beneath the landfill were assumed to one layer of sand.
- Flow Layer Thickness – The flow layer thickness value used was 100 meters. The thickness of unsaturated deposits beneath the lowest landfill liner base elevation (4,022 feet NGVD) and the water table (3,686 feet NGVD (336 feet or 102.4 meters)).
- Saturated Hydraulic Conductivity – Default value for sand (29.7 cm/hr). Table B - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.
- Effective Porosity – Default value for coarse sand (0.34). Table B - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.
- Air Entry Pressure Head – Assumed to be zero (0.0); this value is typically zero for coarser soils. (Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993).
- Residual Water Content – Default value for sand (0.43). Table D - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993;
- vanGenuchten Alpha – Default value for sand (0.145). Table E - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993;
- vanGenuchten Beta – Default value for sand (2.68). Table E - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.

Unsaturated Zone Transport

- Select Transport Layer – Corresponds to Layer 1 of Unsaturated Zone Flow.
- Transport Layer Thickness - Corresponds to Layer 1 of Unsaturated Zone Flow.
- Longitudinal Dispersivity – Derived MultiMed Model.
- Percentage Organic Matter – Default value for Group A: deep sand (0.11). Table K - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.
- Bulk Density – Default value for coarse sand (average of range 1.58). Table G - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.
- Biological Decay Coefficient – Assumed to be zero, i.e. no biological degradation is occurring in the unsaturated zone.

Saturated Zone

- Aquifer thickness – Hueco Bolson aquifer is over 200 meters thick. For this model, an aquifer thickness of 50 meters was used.
- Mixing Zone Thickness – Derived by MultiMed Model.
- Effective Porosity – This value (0.30) was data provided in: Permit Modification, McCombs Landfill – MSW 729A, Groundwater Monitoring System, Task 5, Submittal, prepared by Parkhill, Smith and Cooper and dated July 2009.

- Bulk Density – Default value for coarse sand (average of range 1.58). Table G - Texas Water Commission, Alternative Liner Design Handbook, Version 1, 1993.
- Saturated Hydraulic Conductivity – This value (6,307 m/y) was data provided in: Permit Modification, McCombs Landfill – MSW 729A, Groundwater Monitoring System, Task 5, Submittal, prepared by Parkhill, Smith and Cooper and dated July 2009.
- Hydraulic Gradient – This value (0.0042) was data provided in: Permit Modification, McCombs Landfill – MSW 729A, Groundwater Monitoring System, Task 5, Submittal, prepared by Parkhill, Smith and Cooper and dated July 2009.
- Seepage Velocity – Derived by MultiMed Model.
- Longitudinal Dispersivity – Derived by MultiMed Model.
- Transverse Dispersivity – Derived by MultiMed Model.
- Aquifer Temperature – Assumed 11°C.
- Aquifer pH – Assumed 7.2 standard pH units.
- Fraction Organic Carbon (foc) – Calculated: foc = OM% / (100 x 1.72); foc =11% / (100 x 1.72).
- Aquifer Retardation Factor – Derived by MultiMed Model.
- Aquifer Biological Decay Rate – No biological decay rate modeled.

Well Location and Time

- Radial Distance to Well – Point of Compliance is 125 feet (38 meters) from waste limit boundary.
- Angle off Plume Axis – For Subtitle D application Angle off Plume Axis is fixed at zero.
- Well Screen Fraction – For Subtitle D application Angle off Plume Axis is fixed at zero.

Summary and Conclusion

The MultiMed model was run under the parameters and assumptions listed in the preceding section and in both the active model for unsaturated zone and saturated zone mode. The model parameters reflect a conservative analysis and assume no retardation or degradation. Therefore, the results for both modes are the same, showing no retardation or degradation in the unsaturated zone. The predicted concentration of trichloroethylene at the point of compliance is 0.003412 mg/l, a monitoring point 125 feet directly downgradient of the waste limit boundary. If the model is run with the point of compliance set at one meter from the waste limit boundary, the predicted concentration for TCE is 0.003475 mg/l. Both results are below the established standard, US EPA maximum contaminant level (MCL) of 0.005 mg/l.

Based on the results of the MultiMed Model runs, the alternative liner proposed for the McCombs Landfill will meet the requirements of 30 TAC §330.331.

Alternative Liner Modeling ("Prescriptive Liner")

SAIC®

Memorandum

To: TCEQ

From: Cami Van Abel, SAIC

Subject: Appendix 3J, Attachment 2 – Alternative Liner Modeling (Scenario 1)

Date: March 15, 2013

SAIC has reviewed the attached "Report of Study for Alternative Liner Design Using Single Flexible Membrane Liner, McCombs Landfill, Permit No. 729-A, El Paso, Texas, May 1995" and subsequent revisions dated June 22, 1995 and June 26, 1995. This report was submitted to and approved by the Texas Natural Resources Conservation Commission (TNRCC). The attached Report for the alternative liner modeling for caliche references TNRCC and MSW Permit No. 729A throughout. It should be noted that TNRRC is now Texas Commission of Environmental Quality (TCEQ) and the attached report and data are applicable to the major permit amendment for MSW Permit No. 729B.

Reference to MSW Permit No. 729A should be used synonymously with MSW Permit No. 729B, reference to TNRCC should be used synonymously with TCEQ, and reference to the maximum contaminate levels (Title 31 TAC 330.202) should be used synonymously with 30 TAC §330.331.

Re: McCombs Municipal Solid Waste Landfill
MSW Permit No. 729A
Alternate Liner Design

Dear Mr. Cordova:

On June 1, 1995, the Texas Natural Resource Conservation Commission (TNRCC) Municipal Solid Waste (MSW) Permits Section received a request from the above referenced facility to use an alternate liner design (ALD) pursuant to 30 Texas Administrative Code (TAC) 330.202-Alternate Design. On June 27 and July 6, 1995, clarifications and additional information was submitted to the TNRCC. The proposed ALD consists of a single 60 mil HDPE underlain by a 6 inch compacted caliche on 6 inches of in-situ compacted subgrade. This alternate liner design proposes to replace the currently approved ALD consisting of a double flexible membrane liner with a leachate collection and a leachate detection system. The submitted ALD has been signed and sealed by Danny R. Anderson, P.E. (P.E. # 32062) in accordance with The Texas Engineering Practice Act.

Pursuant to 30 TAC §330.202, Alternate Design:

> Alternate liner designs may be authorized by the executive director if the owner or operator provides a demonstration by computerized modeling (for example, the "Help" and "Multi-Media" models) that show that the maximum contaminant levels detailed in §330.200 of this title (relating to Design Criteria), Table 1 will not be exceeded at the point of compliance. At the discretion of the executive director, a field demonstration may be required to prove the practicality and performance capabilities of an alternative design.

The TNRCC staff has reviewed the submitted ALD and supporting information and has determined that a HELP and Multimed model was submitted in accordance with 30 TAC §330.202. The results of the

P.O. Box 13087 • Austin, Texas 78711-3087 • 512/239-1000
printed on recycled paper using soy-based ink

HELP and Multimed models which are based on the values selected by the consultant and input into the models, indicate that the maximum contaminant levels detailed in 330 TAC §330.200, Table 1 were not exceeded during the remaining active life and post-closure care period.

If you have any questions concerning this letter, please contact Mark Dollins, P.E. at (512) 239-6675.

Sincerely,

Ronald R. Pedde, P.E., Special Assistant

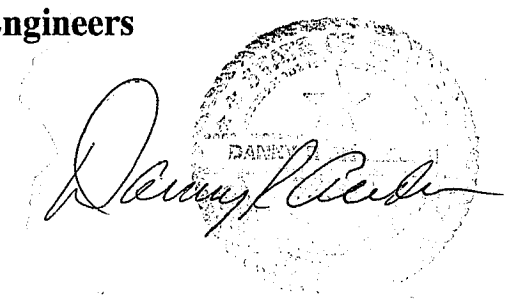
4601 Ripley Drive
El Paso, Texas 79922



ABSTRACT

A new alternate design liner has been proposed by the City of El Paso for the McCombs Landfill to replace the previous approved alternate design liner. These computer models were made to demonstrate the suitability of the new alternate design liner which consists of single flexible membrane liner (FML) with a leachate collection system. Most of the input data used were identical to the previous alternate design liner computer model which consists of double flexible membrane liner.

Two computerized models were utilized, HELP and MULTIMED, together with equations for leachate head over the liner. Two models of MultiMed programs which consist of Subtitle D and Generic Model were generated to determine the maximum contaminant level when it reached the groundwater. In Subtitle D, the groundwater table is assumed to be located at the bottom of landfill and in the Generic Model it is assumed to be at 1 inch below the bottom of landfill. These assumptions give a very conservative approach since the actual groundwater table is located approximately 106 meters (350 feet) below the ground surface as reported in the suitability study of the McCombs Sludge Disposal Landfill in 1987. Points of Compliance (P.O.C) are assumed to be located at the groundwater table level, 1 meter in down gradient direction from the landfill.

Page 1

The results of Subtitle D model shows the Dillution Attenuation Factor (DAF) of 575 which is far greater than 260 (the minimum value required by TNRCC). From the generic model, DAF value of 4630 is obtained. This value is the maximum value which is reached in the 120 years of landfill life.

Some conclusions have been drawn from this study.

1. The amount of leachate which is assumed to pass through the liner system does not have potential for contamination to the groundwater.

2. The depth of existing groundwater provides further protection from contamination.

1. INTRODUCTION

The City of El Paso has decided to propose a new alternate design liner for the McCombs Landfill using single flexible membrane liner. As it is mentioned on the previous approved alternate design liner (ADL), the ADL was proposed due to the existing geologic and site condition of the surrounding landfll area. On site soils and the soil in the vicinity of the proposed landfill are unsuitable to be used as lining materials. The option of importing and processing suitable soils to the site will increase the cost of construction. This alternate design is in compliance with the Title 31 of the Texas Administrative Code (TAC), Section 330.202 which states the following:

Alternate liner designs may be authorized by the executive director if the owner or operator provides a demonstration by computerized design modeling (for example the "Help" and Multi-Media" models) that shows that the maximum contaminant levels detailed in §330.200 of this title (relating to Design Criteria), Table 1 will not be exceeded at the point of compliance. At the discretion of the executive director, a field demonstration may be required to prove the practicality and performance capabilities of an alternative design. Maximum Contaminant Level (MCL), Table 1, can be found on Page 6. The Hydrologic Evaluation of landfill performance (HELP) and Multi-Media Models are programs which model the landfills and the ground-water beneath them. The HELP model utilizes the properties of the soil layers in a landfill, landfill geometric parameters, and the climatic data specific of the area to calculate the amount of leachate

Page 4

in drainage layers of the landfill and the quantity of the leachate which could penetrate the bottom of the liner. The HELP Model also calculates the amount of leachate head on each of the confining soil layers in the landfill.

The Multi-Media Model utilizes the leachate quantity data, unsaturated zone soil parameters, the aquifer parameters, and the geometric landfill parameters to calculate a Dilution Attenuation Factor (DAF) at a specific point outside the landfill boundary. The point outside the landfill boundary may be selected by the modeler and is referred to as the point of compliance (POC). The DAF is the ratio of the initial contaminant concentration in the leachate to the contaminant concentration at the point of compliance.

This study was conducted to demonstrate that the new proposed alternate design liner using a single flexible membrane liner (FML) will provide sufficient protection of the groundwater.

2. SITE INVESTIGATION

The site suitability study of the municipal sludge sanitary landfill, which was conducted in 1987, was used to provide data for the computer simulations. The above landfill is located beside the proposed Subtitle D landfill. The proposed site of Subtitle D landfill is shown on Figure 1. The summary of the above study is as follows:

2.1 CLIMATE AND PHYSIOGRAPHIC SETTING

El Paso lies within the Chihuahuan desert climate region which is characterized by small but variable precipitation, large annual and diurnal temperature ranges, low relative humidity, and abundant sunshine throughout the year.

High summer daytime temperatures, mild winter daytime temperature, low humidity, and moderate winds combine to create an average annual potential evapotranspiration of 79.7 inches.

The proposed landfill site lies on the broad lowland surface of the Hueco Bolson, on intermontane basin typical of the Mexican Highlands subsection of the Basin and Range Physiographic Province. The Hueco Bolson is a north-south trending tectonic trough with basin-fill deposits, extending from southernmost New Mexico through western Texas and into northern Chihuahua. The Hueco Bolson is bounded on the north by the Tularosa Basin (topographically indistinct but hydrologically separate), on the west by the Franklin

Page 7

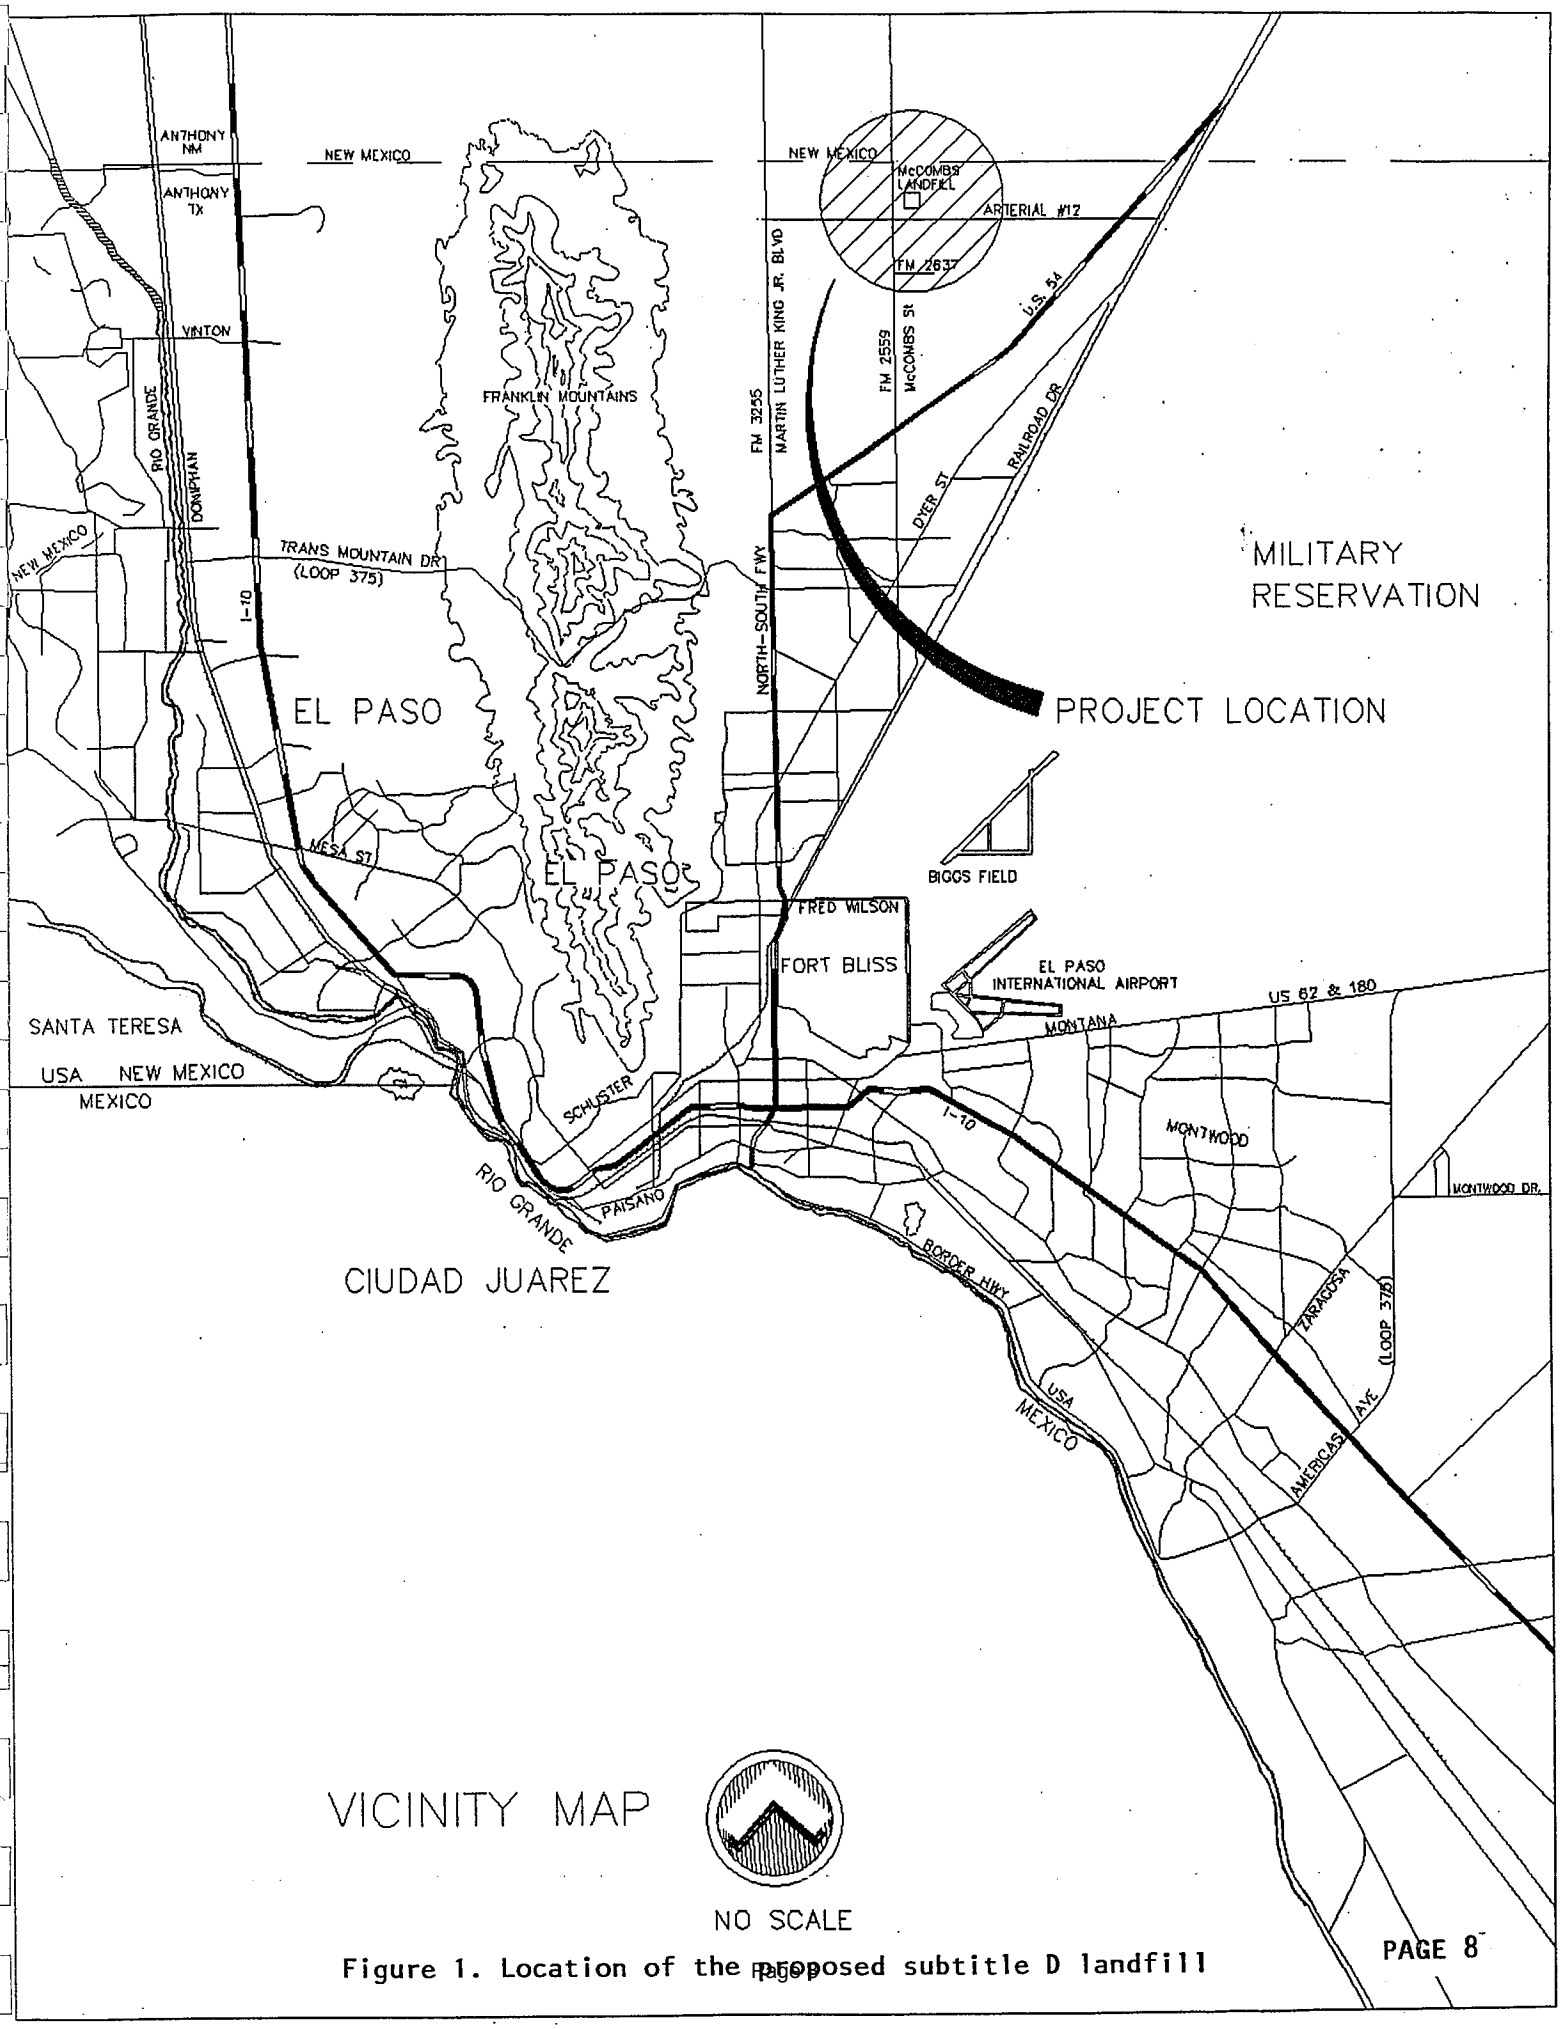

Figure 1. Location of the proposed subtitle D landfill

Mountains (a tilted fault block), on the east by the Hueco Mountains (limestone with some igneous intrusions), and on the south by mountain ranges of the Sierra Madre Occidental Massif.

Basin-fill deposits range up to 2740 meters (9000 feet) deep near the Franklin Mountains. The upper 430 meters (1400 feet) in this portion of the Bolson are predominantly alluvial sands and gravels, thinning to the east. Lacustrine deposits predominate below the fluvial sediments with basement rock of granite and limestone (Figure 2). Alluvial fan and eolian deposits interfinger with both dominant facies at depth and also comprise the more recent surficial deposits. Both facies are considered part of the Fort Hancock Formation, although some assign fluvial gravels in the upper facies as part of the Camp Rice Formation, distinct from piedmont slope alluvial deposits and the lower Lacustrine facies. When crossing the Hueco Bolson, one is aware of the ridge and swale topography which is also evident as aligned depressions on LANDSAT imagery, perhaps representing relict drainage features. Present-day drainage is primarily internal and non-integrated, with rare surface runoff accumulating briefly in playas or small depressions.

An Eastern Boundary Fault Zone (EBFZ) is proposed as separating the Franklin Mountains from the bolson deposits and would be buried under recent piedmont slope deposits and relict landslide blocks (Figure 2). Between 6100 and 7620 meters (20,000 and 25,000 feet) of vertical displacement is said to have occurred along this fault which

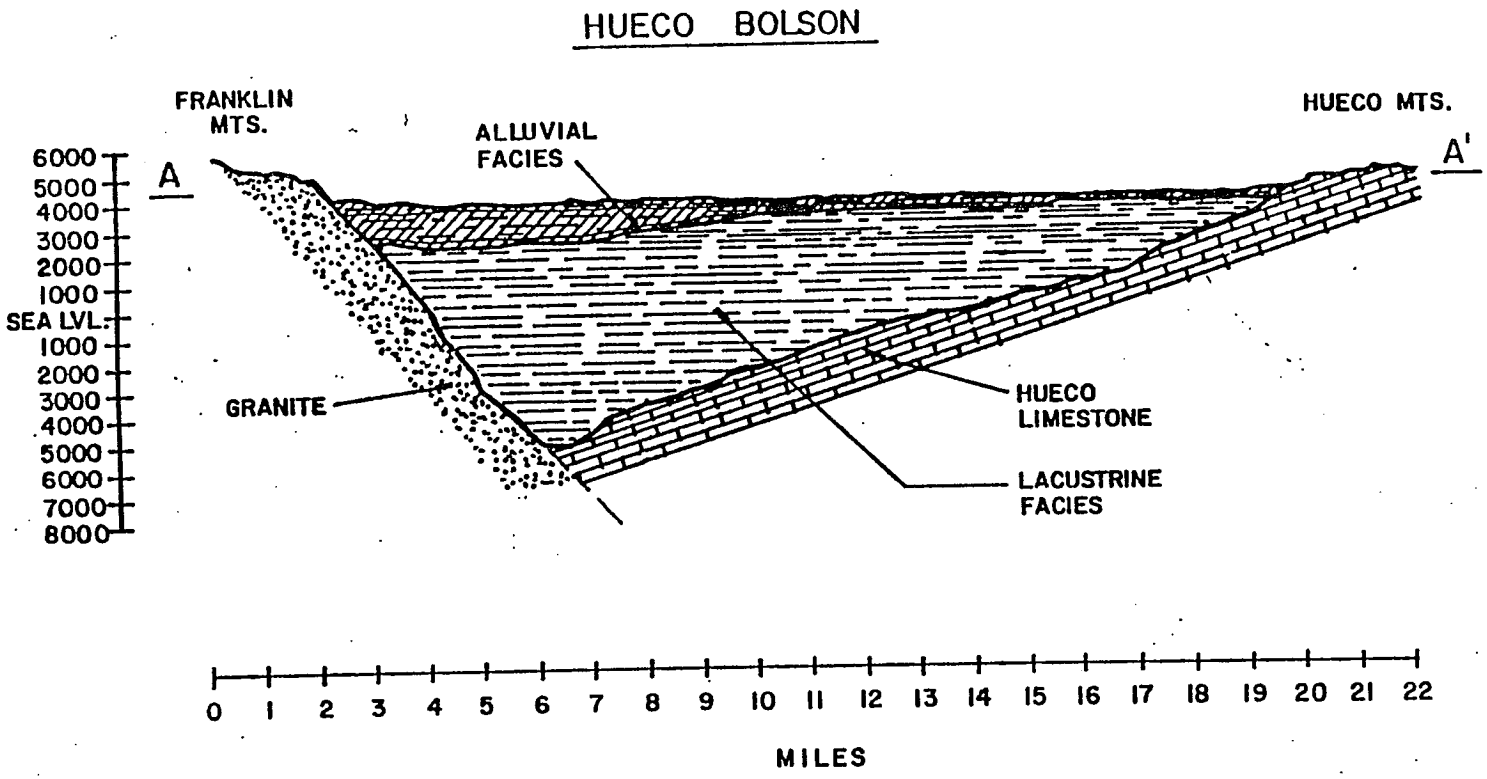

FIG. 2 A WEST - EAST GEOLOGIC CROSS-SECTION OF THE HUECO BOLSON.

dips 25° eastward, based on gravity and seismic data. Movement was initiated during the early Laramide, between 50 and 156 million years ago and has probably decreased ever since. Movement of 122 meters (400 feet) along the EBFZ is suspected since deposition of the upper portion of the Bolson-fill. Westward tilting of the bolson along this fault zone led in part to deposition of the Rio Grande fluvial sediments which thins to the east, (as mentioned earlier), and which today comprise the most productive regional aquifer. The westward tilting along the EBFZ also accounts for the decline in surface elevation of about 61 meters (200 feet) over 13 kilometers (8 miles) from east to west.

2.2 SITE CONDITIONS AND SUBSOIL PROFILE

2.2.1 The proposed construction site is located in the Hueco Bolson. The soils in this area are related to the Turney-Berino Association which is described as nearly level and gently sloping soils that have a clay loam subsoil and are moderately deep over soft caliche.

2.2.2 The large deficit between precipitation and potential evapotranspiration restricts vegetation in this region. The potential plant community is made up of grass decreasers as bush muhly, black grama perennial three-awns, plains bristle grass, mesa drop seed and sand drop seed, common invaders are mesquite, creosote bush and brown snake weed.

Page 11

2.2.3 Subsurface soils encountered from 5 test borings are reported in the Appendix. Predominantly three strata of soil material were encountered; silty sand, clayey sand and poorly graded sand. Silty clayey sand is found near the ground surface and extends from the elevation of 4030 feet to 3988 feet while poorly graded sand is found at the elevation of 3988 feet and extends to 3935 feet. Groundwater was not encountered at any of the test boring locations during the time of the investigation.

2.3 GROUNDWATER

2.3.1 Regional Distribution

Water bearing sediments in the Hueco Bolson are very lenticular in nature, consisting of mixed rounded sands and gravels (left by the ancestral Rio Grande), poorly graded piedmont slope sands and clays (derived locally from granitic outcrops), and well graded piedmont slope sands (derived locally from sandstone outcrops and eolian deposits). Hydrostatrigraphic units of lower permeability involve Lacustrine clays mixed with pebbles of chert (derived locally from outcrops of shale and limestone).

Groundwater is primarily unconfined beneath the broad lowland surface of the Hueco Bolson; this portion of the aquifer is known as the Mesa area. In the Rio Grande Valley between El Paso and Ysleta, groundwater in bolson deposits is semi-confined beneath discontinuous clay lenses left when the river had entrenched 60 to 80 meters (200 to 260 feet) beneath the current valley floor elevation; this portion of the Hueco Bolson aquifer

Page 12

is known as the City Artesian Area. The static water table in the Mesa Area generally ranges in depth below the land surface from 260 to 380 feet dated December 1986. Drawdown in the Mesa Area in the 20 year period, between 1964-1984 ranges from 10 feet in northeast El Paso to 60 feet in the El Paso International Airport, surrounding area (see Figure 3). Disregarding the City Artesian Area median well depth is 168 meters (550 feet) with 67 percent of wells between depths of 90-245 meters (300-800) feet (Figure 4).

2.3.2 Movement

The water table has a hydraulic gradient of about 0.0025 (13 feet per mile) towards a major cone of depression in the vicinity of El Paso International Airport. Groundwater surface contours are provided to illustrate flow directions (Figure 5). Recharge is restricted to deep percolation at the contact between bedrock and alluvium from precipitation of the east slope of the Franklin Mountains. Average annual recharge is estimated at 7.4 million cubic meters (6000 acre-feet), contrasted with 1980 pumpage requirements of 111.7 mcm (90,590 acre-feet). With projected increases in demand for Hueco Bolson groundwater, 75 percent of the volume in storage will be depleted between 1980 and 2030. Transmissivity of the Mesa Area aquifer ranges from 990 to 1980 m^2/day (80 to 160 gal/day/ft); vertical hydraulic conductivity is approximately 20 gal/day/ft^2; while horizontal hydraulic conductivity is approximately 200 gal/day/ft^2; storage coefficient (specific yield) ranges between 0.16 to 0.30; well yields average 9760 m^3/day

Page 13

(1.79 gal/min); specific capacity of wells averages 0.5m^3/day/m.

2.3.3 Quality

The quality of groundwater in the Mesa Area of the Hueco Bolson aquifer is characterized by steady increases in total dissolved solids (TDS) with increasing depth (Figure 3). The thickness of groundwater containing 300-500 mg/1 TDS reaches a maximum of 275 meters (900 feet); the thickness of groundwater with 300 to 2500 mg/l reaches a maximum of 305 meters (1000 feet).

2.3.4 Existing Well

The Texas ownership doctrine for groundwater allocation dictates that municipal water supply wells must be located within El Paso City limits or located where water rights have been acquired from the landowner. The ownership doctrine thereby accounts for the high density of wells in the Mesa Area portion of the Hueco Bolson aquifer beneath city land, as opposed to those located beneath Fort Bliss (Figure 5).

Several wells exist in the vicinity of the proposed landfill site (Figure 6). Well #314 is owned by El Paso Sand Products Company, a quarry operation which adjoins the proposed landfill site on the west. The well is drilled to a depth of 142 meters (465 feet). Static water level is approximately 116 meters (350 feet) below land surface. The well is slotted for the entire depth below static water level but no water quality analyses are

Page 14

available.

Hydraulically up-gradient and within a one-mile radius from the proposed landfill site are two existing wells (Well #310 was a USGS test well that was filled in). Well #213 is owned by the El Paso Electric Company and is not oriented along any flow line relative to the proposed landfill site. This well is drilled to a depth of 267 meters (875 feet). Static water level is approximately 102 meters (340 feet) below land surface. The well is slotted for the entire depth below 136 meters (445 feet), discharging water with 797 mg/l TDS (Jan. 15, 1976 measurement). Chloride was reported at a level of 350 mg/l, the only ion to exceed current EPA National Interim Primary Drinking Water Standards. Well #309 is an El Paso City municipal water supply well located 0.32 km (0.2 mile) distant as measured along flow lines. This well is drilled to a depth of 242 meters (795 feet). Static water level is at the elevation of 3689.31 feet approximately 102 meters (335 feet) below land surface (December 1986 measurement). The well is slotted between 155 and 168 meters (510 and 550 feet) and between 186 and 198 meters (610 and 650 feet) depth, discharging water with 505 mg/l TDS (Oct. 6, 1965 measurement). Hydraulically down-gradient and within the one-mile radius from the proposed landfill site are three city-owned wells. Well #305 is drilled to a depth of 184 meters (603 feet) and is 0.2 km (0.1 mile) distant as measured along flow lines. Static water level is approximately 104 meters (340 feet) below land surface. This well is screened between 114 and 152 meters (374 and 1199 feet) depth, discharging water with 436 mg/l TDS (Nov. 1, 1974

measurement). Well #306 is drilled to a depth of 184 meters (603 feet) and is 0.5 km (0.3 mile) distant but not along any flow lines which cross the proposed landfill site. Static water level is approximately 116 meters (379 feet) below land surface. This well is screened for the entire depth below 119 meters (391 feet) depth, discharging water with 1459 mg/l TDS (July 5, 1965 measurement; the chloride and sulfate anions did not meet EPA standards. Well #301 is drilled to a depth of 205 meters (671 feet) and is 1.6 km (1 mile) distant as measured along a flow line. Static water level is approximately 109 meters (358 feet) below land surface (December 1985 measurement). This well is slotted from 98 to 154 meters (320 to 505 feet) and again below 155 meters (507 feet), discharging water with 400 mg/l TDS. Well #303 is owned by Prices Dairy and is not located along any flow lines which intersect the proposed landfill site. This well is drilled to a depth of 265 meters (870 feet) with static water level at approximately 116 meters (380 feet) below land surface (January 1987).

2.4 UNSATURATED AND SATURATED ZONE CHARACTERISTICS

2.4.1 Unsaturated Zone Characteristics

Subsurface soils encountered from five test borings and three wells (see Appendix A) indicate poorly graded silty sand and clayey sand with low to medium plasticity index are the dominant material in the unsaturated zone.

Page 20

2.4.2 Saturated Zone Characteristics

Static water table is between 102 and 110 meters (335 and 360 feet) below the land surface at the proposed landfill site. This represents a decline in water table elevation of 10 feet to 60 feet during the past twenty years, 1964 to 1984. The water table has a hydraulic gradient (i) of 0.0025, sloping SSW so that groundwater beneath the proposed landfill site moves NNE and SSW. The gradient and direction of the water table surface have also been modified from conditions in 1903, when i = 0.0009 sloping to the east. Within the one-mile radius study area, aquifer transmissivity is 170 m^2/day (140 gal/day/ft) for the upper 133 meters (440 feet) of the saturated zone; horizontal hydraulic conductivity is (250 gal/day/ft^2). The groundwater flow per unit width of aquifer will be q_w=KDi=Ti=(1740 m^2/day) (0.0025) = 4.35 m^3/day/m.

A standard thickness (d) of 133 meters (440 feet) is used since this is the local thickness of groundwater containing 300 to 2500 mg/l TDS.

Page 21

3. DATA AND MODELING CASES

3.1 DATA

The normal mean monthly precipitation and normal mean monthly temperature, during a period of 30 years (1961-1990), were used to run the simulation for the HELP program model. These climatological data were obtained from the National Weather Services in El Paso, Texas. The input parameters were summarized and reported on Page 26.

Input parameters for the Multi-Media program consists of two groups of data. The first group of data was used for Subtitle D Model and the second group of data was used for the Generic Model. These parameters were tabulated in Table 3.1 through Table 3.3 for the Subtitle D Model and Table 3.4 through Table 3.7 for the Generic Model. In order to simplify the simulation Model, the Unsaturated Zone layer is assumed to consist of one homogeneous layer (clean sands). As described in Section 2.2.3, the existing unsaturated layer consist of silty sand, clayey sand and poorly graded sand. Thus, it has a lower hydraulic conducitivity value than those of the assumed layer. Therefore, a conservative result will be obtained.

Since the silty clayey materials in the unsaturated zone will decrease, or prohibit the vertical movement of contaminant, the vertical hydraulic conductivity value will not be excessively higher than the horizontal hydraulic conductivity value.

Page 22

The saturated zone is also assumed to consist of one homogeneous layer of sand-coarse material. As indicated in Section 2.4.2, the hydraulic gradient and the thickness of the aquifer were taken as 0.0025 and 133 meters respectively.

The quantity of leachate assumed to be leaking through the liner, which must be estimated to provide the input data used in the Multi-Media Model, was calculated based on the leakage equations in the TNRCC Handbook. This equation has been modified to take into account the thin lining system. The equations used the amount of head on the liner to determine leakage rates. This head value was obtained from the HELP Model.

The above mentioned equations were obtained from the Johnson Ranch II Subtitle D cell, the alternate liner notebook from the City of Odessa, Texas. The alternate liner design was used by the City of Odessa for permit modification of the Johnson Ranch II - Subtitle D landfill on November 1993. The calculation of leachate rates is reported on Appendix C.

The Hydraulic Conductivity of the Flexible Membrane Liner (FML) was assumed to be 5 x 10E-9 cm/sec. This hydraulic conductivity value was estimated based on a study performed by Paula Estornall, a geotechnical engineer at Hart-Crowser Associates in Seattle, WA and Dr. David Daniel (a professor of civil engineering at the University of Texas at Austin) (see Appendix G).

Page 29

3.2 MODELING CASES

3.2.1 HELP Modeling Run

The proposed alternate design liner consists of 24″ of protective cover, a flexible membrane liner (60 mil HDPE) over 6″ of compacted caliche soil. In HELP Model, 24″ protective cover is functioned as a drainage layer and is underlain by barrier soil liner with flexible membrane liner. The protective cover layer is assumed to be consisting of sand layer with coefficient of permeability of 1×10^{-3} cm/sec.

3.2.2 Multi-Media Modeling Run

Two models were generated in this program, the Subtitle D Model and the Generic Model. In the Subtitle D Model the program was run based on the steady-state mode. Where in the Generic Model the transient mode was used.

As was mentioned before the unsaturated layer in generic model is assumed consist of 1 m (3.3 feet). This will ensure that a very conservative result will be obtained. The contamination level at point of compliance was investigated in the time frame of 200 years. Where in the Subtitle D Model, the time factor is neglected because it is based on a steady state mode.

Page 30

The points of compliance are assumed to be located on the groundwater table level 1 meter away from the landfill in down gradient direction. The ground water table level is under the assumption that it is located on the bottom of landfill for Subtitle D Model and 1 meter below the bottom of landfill for the generic model.

Page 31

4. PRESENTATION OF RESULT

The leachate concentration levels at the point of compliance were calculated by dividing the leachate concentration by the DAF as recommended in the TNRCC Handbook and do not account for the background water quality. These results are reported on Page 34 and Page 35. The Dilution Attenuation Factor (DAF) is calculated by dividing initial concentration (TNRCC=1.0) with the concentration at the Point of Compliance. The location of the Point of Compliance, maximum leachate concentration at POC, and the Dilution Attenuation Factor (DAF) is tabulated in Table 4.1.

MODEL GENERATED	LOCATION OF POC	CONCENTRATION	DAF
Subtitle D	Bottom of landfill 1 m in down gradient	0.1738E-02 m	575
Generic	1 m below the bottom of landfill, 1 m in down gradient	0.2160E-03	4630

TABLE 4.1 CONCENTRATION AND DAF VALUE AT POINT OF COMPLIANCE

The results which were obtained from the Subtitle D Model shows that the DAF values are at the range of 575. This value is obtained at the steady state condition, which is very conservative because it requires that the water entering the flow system be balanced by the water leaving the system. This system also requires that the contaminant source have a sufficiently large mass to ensure that the downgradient concentration once reached will

Page 32

be maintained. Furthermore, it also required that the source contaminant be continuous and constant. This condition will hardly be achieved in the existing site condition.

The concentration level at point of compliance from the generic model shows the value of 4630. This value will be achieved after 120 years with the assumption that the landfill is an active landfill. The relationship between the concentration of leachate at point of compliance relative to time is shown in Figure 7.

Notes:
1. POC contaminant levels are calculated as recommended in the TNRCC Alternate Liner Design Handbook and do not account for background groundwater quality.
2. Leachate concentration levels were obtained from the TNRCC Alternate Liner Design Handbook
3. The flouride concentration was obtained from a Missouri Department of Natural Resources study.
4. No data is available on typical concentration of Methoxychlor, Nitrate, or 1,1,1-trichloroethane.

1. POC contaminant levels are calculated as recommended in the TNRCC Alternate Liner Design Handbook and do not account for background groundwater quality.
2. Leachate concentration levels were obtained from the TNRCC Alternate Liner Design Handbook
3. The flouride concentration was obtained from a Missouri Department of Natural Resources study.
4. No data is available on typical concentration of Methoxychlor, Nitrate, or 1,1,1-trichloroethane.

Page 35

GENERIC MODEL SIMULATION RESULT

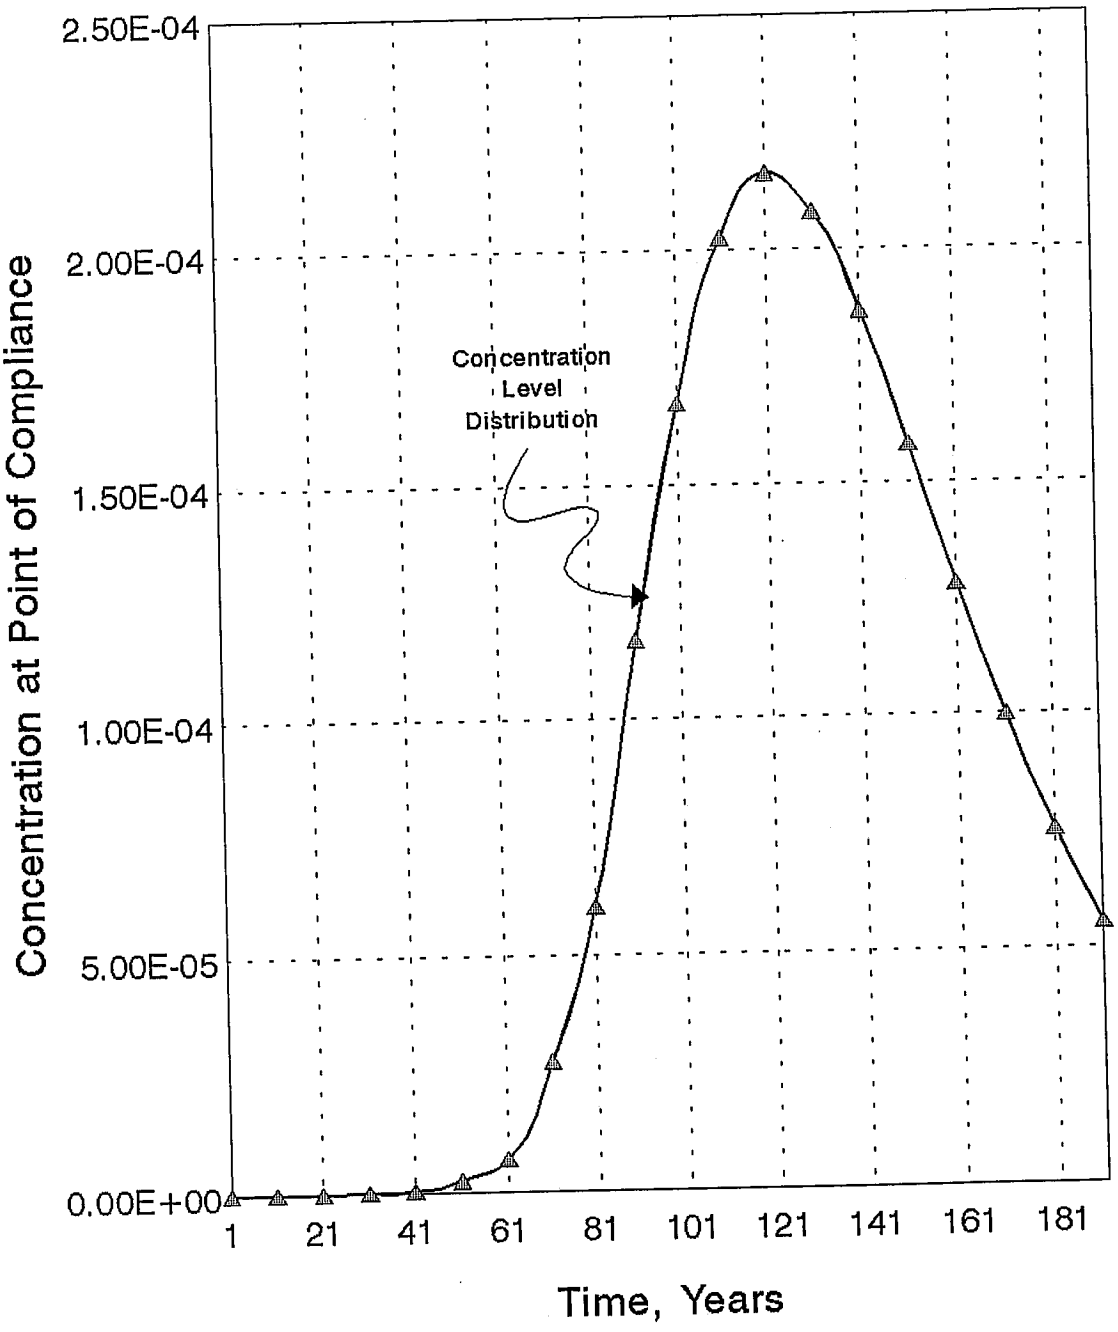

Figure 7. Concentration at Point of Compliance relative to Time

Page 36

5. DISCUSSION AND CONCLUSION

None of the concentration levels at the Point of Compliance exceeds the maximum concentration level, which is recommended by TNRCC. The Alternate Design Handbook on Page 24 and 25 indicates that the minimum Dilution Attenuation Factor (DAF) should be 260. Where in this study the minimum Dilution Attenuation Factor is approximately 575. This value far exceeds the above requirement.

The Generic Model result indicates the DAF value at P.O. C. is 4630. These results show that the contaminants have been diluted at least 575 times when it reaches the P.O.C.

The above results indicate that the amount of leachate which passes through the liner system is considered insignificant and it will take more than 200 years to reach the DAF of 575 at the POC, which is located at 1m in down gradient from the landfill and at a depth of 1 m below the bottom of landfill. That is, by assuming that the unsaturated layer consist only of clean sand layer. If the thickness of unsaturated zone increases, the longer the time that is needed by the leachate to penetrate the unsaturated zone.

Page 37

Based on this study, we recommend a construction of Subtitle D cell at McCombs Landfill using an alternate liner. The alternate liner design will consist of a single 60 mil Flexible Membrane Liner (FML) overlain by 24" of protective cover, with a leachate collection system. Consequently, we recommend that no further site specific soil sampling and testing be performed and ground water monitoring be waived.

APPENDIX C

"HELP" CALCULATION (FLOW)

- Calculation of Leachate on Liners

$$Tmax = L \frac{\sqrt{4(e/k)+\tan^2(\beta)} - \tan(\beta)}{2\cos(\beta)}$$

(TNRCC Alternate Liner Design Handbook, page 9)

where:

Tmax = Maximum thickness of leachate in the leachate collection layer.

L = Length of horizontal projection of the leachate collection layer (meters).

e = Impingement rate (meters/sec).

k = Hydraulic conductivity of drainage layer (meter/sec).

ß = Slope angle of the base of the leachate collection layer (degrees).

e = 0.0045 inches/day = 114.3×10^{-6} m/day

$$= \frac{114.3 \times 10^{-6} \text{ m/sec/sec}}{86400}$$

$$= 1.323 \times 10^{-9} \text{ m/sec}$$

L = 270 feet = 82 meters.

K = 10^{-3} m/sec = 10^{-5} m/sec.

ß = 3%

$$Tmax = 82 \left[\frac{\sqrt{4(1.323 \times 10^{-9}/10^{-5})+\tan^2(3°)}-\tan(3°)}{2\cos(3°)}\right]$$

$$= 82 \left[\frac{\sqrt{5.292 \times 10^{-4} + 274.66 \times 10^{-5}} - 0.0524077}{1.9973}\right]$$

$$= 82 \left[\frac{0.0572346 - 0.052407}{1.9973}\right]$$

$$= 82 \ (0.0024167)$$

$$= 0.1982 \text{ meter} = 0.6503 \text{ feet} = 7.803 \text{ inches}$$

Calculated T max = 7.8031 inches is less than the maximum value of 12 inches (TNRCC Handbook).

- Calculation of Infiltration Rate (Q)

  -assume that FML have a "Good Placement"

$$R = 0.26a^{0.05} \times H^{0.45} \times Ks^{-0.13} \left(\frac{\mu 25}{\mu 15}\right)$$

where

a = area of hole = 0.16 in² = 1×10^{-4} m² (TNRCC, Alternate Design, Page 11).

H = Hydraulic head on top of geomembrane liner (meter). (HELP, YIELD - 15 inches) 15 inches = 0.381 meters.

Ks = Hydraulic Conductivity of low permeability soil underlying geomembrane = (5×10^{-9} cm/sec = 5×10^{-11} m/s).

μ^{25} = Viscosity of water at 25°C = 0.000890 (N s/m²)

μ^{15} = Viscosity of water at 15°C = 0.001139 (N s/m²)

$$R = 0.26(1\times10^{-4})^{0.05} \times (0.381)^{0.45} \times (5\times10^{-11})^{-0.13} \left(\frac{0.000890}{0.001139}\right)$$

= 1.81297 inches

$$L \text{ avg.} = 1 + \frac{H}{2Hs \ \ln(R/Ro)}$$

H = Hydraulic head as top of Geomembrane = 0.381 meters.

Hs= Thickness of low permeability soil = 0.30" = 0.00762 m.

R = from Above = 1.81297 meters

Ro= Radius of imperfection = 0.226" = 0.00574m

$$L_{avg} = 1 + \frac{0.381}{2(0.00762)\ln\left(\frac{1.81297}{0.00574}\right)}$$

$$= 1 + \frac{0.381}{0.087710199}$$

$$= 5.343850594$$

$$Q = Ks\ L\ \pi\ R^2\ \left(\frac{\#defects}{acres}\right)(area) \rightarrow$$

area assume = 22 acres

$$Q = (5 \times 10^{-11})(5.343850594)(3.14)(1.81297)^2\left(\frac{7}{acre}\right)(22\ acres)$$

$$= 424.674 \times 10^{-9}\ m^3/sec.$$

$$Q = (424.674 \times 10^{-9}\ m^3/sec)\left(\frac{31536000\ sec}{year}\right)\left(\frac{1}{19182 m^2}\right)$$

$$= 698.182 \times 10^{-6}\ m/year \quad \text{(MULTIMED INPUT)}$$

$$\approx 0.698 \times 10^{-3}\ m/year$$

THE DAILY VALUES PRESENTED IN THESE TABLES ARE NOT SIMPLE MEANS OF OBSERVED VALUES. THEY ARE INTERPOLATED FROM THE MUCH LESS VARIABLE MONTHLY NORMALS BY USE OF THE NATURAL SPLINE FUNCTION. IN LEAP YEARS USE THE FEBRUARY 28TH VALUES FOR THE 29TH AND ADJUST THE DEGREE DAY MONTHLY TOTALS ACCORDINGLY. DAILY PRECIPITATION NORMALS WERE ALSO COMPUTED USING THE NATURAL SPLINE FUNCTION AND DO NOT EXHIBIT THE TYPICAL DAILY RANDOM PATTERNS. HOWEVER, THEY MAY BE USED TO COMPUTE NORMAL PRECIPITATION OVER TIME INTERVALS.

CLIMATOGRAPHY OF THE UNITED STATES NO. 84
DAILY NORMALS OF TEMPERATURE, HEATING AND COOLING DEGREE DAYS, AND PRECIPITATION 1961-90

PREFACE

This publication presents daily temperature, heating and cooling degree day, and precipitation normals for selected stations based on the 1961-90 record, adjusted to the present station location. The following elements are presented:

MAX = Maximum Temperature (°F)
MIN = Minimum Temperature (°F)
AVG = Average Temperature (°F)
HDD = Heating Degree Days (Standard Base of 65°F)
CDD = Cooling Degree Days (Standard Base of 65°F)
PCP = Precipitation (Inches)

The stations included in this publication are the National Weather Service Offices and Principal Climatological Stations included in Climatography of the United States No. 81 (1).

The daily values presented in these tables are not simple means of the observed daily values. They are interpolated from the much less variable monthly normals by use of the natural spline function as described by Greville (2). The procedure involved constructing a cumulative series of monthly sums from the monthly normals. The cumulative series was for a 24-month period (July, . . . December, January, . . . December, January, . . . June) so the interpolating function could adequately fit the end points of the annual series. This process was applied independently to all six elements. No normal values for February 29 are included here; in common practice the normal values for the 28th are used for the 29th in each leap year. Thus, for leap years, the February monthly total degree day values are calculated by adding the daily value for the 28th to the printed monthly total. The February temperature and precipitation monthly values are not adjusted for leap years.

The monthly heating and cooling degree day normals (base 65°F) are derived from the monthly normal temperatures using the technique developed by Thom (3), (4). An asterisk (*) for a daily degree day value indicates a daily normal of less than one degree day, but not equal to zero.

Environmental Information Summary C-28 has a more detailed discussion of the daily normals procedure and a discussion of the monthly precipitation probabilities and quintiles.

The EIS C-28 brochure and additional information about the climate of the city listed in this publication may be obtained from the NCDC, Federal Bldg., 37 Battery Park Avenue, Asheville, NC 28801-2733, or by calling 704-259-0682.

APPENDIX G

Hydraulic Conductivity of Three Geosynthetic Clay Liners

By Paula Estornell[1] and David E. Daniel[2]

Abstract: The hydraulic conductivity of three 2.9 m^2 (32 sq ft) geosynthetic clay liners (GCLs) was measured. Tests were performed on individual sheets of the GCLs, on overlapped pieces of GCLs, and on composite liners consisting of a punctured geomembrane overlying a GCL. Hydraulic conductivities of two of the GCLs were in the range of 10^{-10} to 10^{-8} cm/s. No flow was measured through the third GCL, but the conductivity was obviously very low ($<< 10^{-7}$ cm/s). The hydraulic conductivities of overlapped GCLs were about the same as those of the control samples with no overlap; an effective hydraulic seal developed along the overlaps in all of the materials tested. Performance of the punctured geomembrane-GCL composites varied—performance was best when the punctured geomembrane was placed directly against bentonite and no geotextile separated the punctured geomembrane from the bentonite. For those GCLs with geotextiles on both sides, problems with migration of bentonite into the underlying drainage layer were encountered when inadequate filtration was provided. However, with a suitable filtration layer separating the drainage layer from the GCL, problems with migration of bentonite were eliminated.

Introduction

A layer of low-hydraulic-conductivity compacted soil is a required component of most liner and cover systems at waste-containment facilities. In the past few years, several thin, prefabricated, clay blankets, called geosynthetic clay liners (GCLs), have been developed and proposed as an alternative to compacted clay in liner and cover systems. Geosynthetic clay liners may supplement required components in waste-containment units or, as proposed by some, replace part or all of the low-hydraulic-conductivity compacted-soil liner (Daniel and Koerner 1991). Daniel and Estornell (1990), Eith et al. (1990), Grube (1991), and Grube and Daniel (1991) review advantages and disadvantages of GCLs for various waste-containment applications.

The research described in this paper was performed to develop technical information on the engineering properties of GCLs, to determine the hydraulic properties of GCLs and the overlapped seams, and to evaluate the composite behavior of geomembrane-GCL composite liners.

Geosynthetic Clay Liners

Three geosynthetic clay liners (GCLs) were investigated: Bentomat, Claymax, and Paraseal/Gundseal. A fourth GCL, Bentofix (Scheu et al. 1990), manufactured in Germany, was not included in this study. The three GCLs investigated are shown in Fig. 1.

Bentomat is manufactured by the Colloid Environmental Technologies Co. (CETCO) in Villa Rica, Georgia. The material that was tested consisted of 4.9 kg/m^2 (1 lb/sq ft) of untreated, Volclay sodium bentonite ("CS" grade) sandwiched between woven and nonwoven geotextiles that are needle punched together (Fig. 1) to contain the bentonite and to enhance in-plane shear strength.

Claymax is manufactured by the James Clem Corp. in Fairmont, Georgia. The material that was tested consisted by 4.9 kg/m^2 (1 lb/sq ft) of sodium bentonite sandwiched between two woven geotextiles (Fig. 1). The lower geotextile is a lightweight, open-weave, spun-lace polyester with large openings. A water-soluble glue is mixed with the bentonite to hold the components together until the GCL has been installed.

Paraseal/Gundseal is manufactured by Gundle Lining Systems, Inc., and Paramount Technical Products, Inc., (see Appendix I) in Spearfish, South Dakota. The material that was tested consisted of 4.9 kg/m^2 (1 lb/sq ft) of sodium bentonite mixed with an adhesive and attached to a 0.5 mm (20 mil) thick high-density polyethylene (HDPE) geomembrane (Fig. 1). Material tested in this study was Paraseal, but Paraseal and Gundseal are functionally identical.

Geosynthetic clay liners are manufactured in panels with widths of 4–5 m (13–17 ft) and lengths of 25–60 m (80–200 ft). The panels are placed on rolls at the factory and unrolled at the time of installation. The panels are overlapped 75–225 mm (3–9 in.) during installation and are said to be self-sealing at the overlap. Fig. 2 shows a sketch of the overlap zones. In the case of Bentomat, additional sodium bentonite is placed along the overlap at a rate of 0.4 kg/m (0.25 lb/ft). The bentonite penetrates the pores

Note. Discussion open until March 1, 1993. To extend the closing date one month, a written request must be filed with the ASCE Manager of Journals. The manuscript for this paper was submitted for review and possible publication on September 20, 1991. This paper is part of the *Journal of Geotechnical Engineering*, Vol. 118, No. 10, October, 1992. ©ASCE, ISSN 0733-9410/92/0010-1592/$1.00 + $.15 per page. Paper No. 2605.

Page 79
G-1

of the geotextiles, and the manufacturer says it causes the material to self-seam when the bentonite hydrates.

Claymax panels are normally placed with the open-weave, polyester backing facing downward (Fig. 2). When the bentonite hydrates, the manufacturer states that the bentonite oozes out through the openings in the geotextiles and causes the material to self-seal.

With Gundseal, the GCL can be placed with the bentonite facing upward or, as shown in Fig. 2, downward. The material is said to be self-sealing at the overlap. Although no mechanical joining of overlapped seams is necessary for any of the GCLs, the HDPE sheets in Gundseal can be welded together along the overlaps, if desired, but a thicker HDPE sheet than the usual 0.5-mm (20-mil) sheet would be required. Gundseal would be placed with the bentonite facing upward if a separate, conventional geomembrane lining is to be placed on top of the GCL.

More information about GCLs is available from the manufacturers and from Schubert (1987), Daniel and Estornell (1990), Shan (1990), Eith et al. (1990), Bruton (1991), Estornell (1991), Grube (1991), Grube and Daniel (1991), Shan and Daniel (1991), and Trauger (1991).

Experimental Methods

Steel tanks, shown schematically in Fig. 3, were fabricated for bench-scale hydraulic conductivity tests. The tanks measured 2.4 m (8 ft) long, 1.2 m (4 ft) wide, and 0.9 m (3 ft) tall. A 13 mm (0.5 in.) diameter drainage

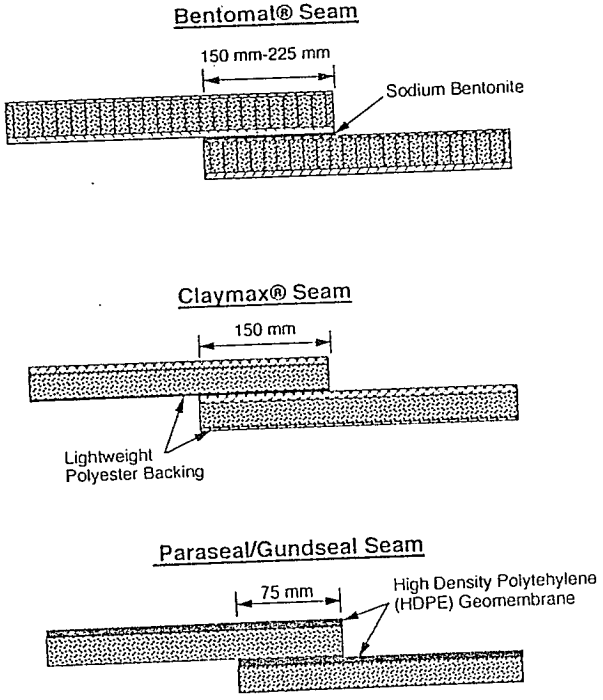

FIG. 2. Configuration of Overlapped Seams with Manufacturers' Minimum Recommended Overlap Width

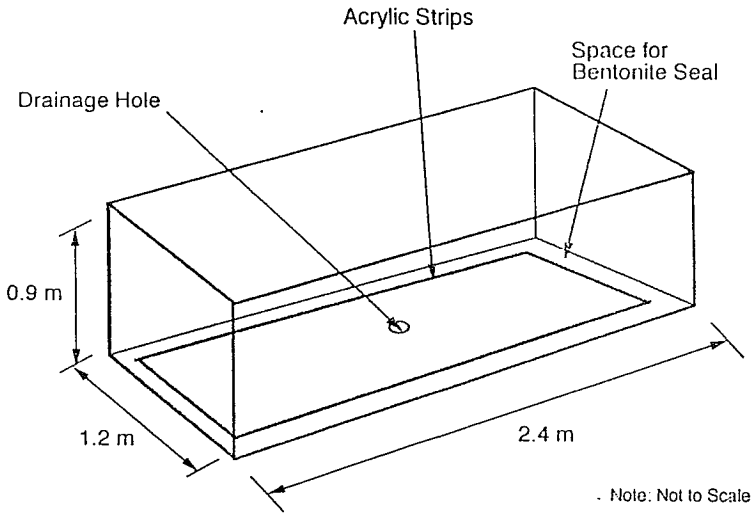

FIG. 3. Orthogonal View of Tank Used for Bench-Scale Hydraulic Conductivity Tests

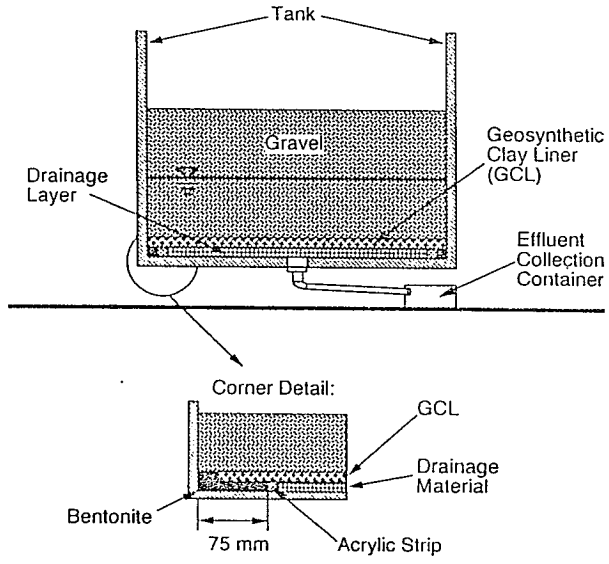

FIG. 4. Cross-Sectional View of Configuration of Materials in Tanks

hole was drilled in the center of the base (Fig. 3) of each tank. The inside walls of the tanks were coated with epoxy. The tanks were raised about 150 mm (6 in.) off the floor with wooden supports.

Acrylic fittings with PVC elbows and flexible plastic tubes were attached to the drainage holes at the bottom of each tank, as shown in Fig. 4. This outlet system provided a closed channel for effluent drainage. In addition, 6.4 mm by 6.4 mm (1/4 in. by 1/4 in.) acrylic strips were glued to the bottoms

of the tanks in a rectangular pattern, as shown in Fig. 3. The acrylic strips provided a 75 mm (3 in.) wide space around the edges of the tanks to retain bentonite that was placed to seal the GCLs against the edges of the tanks.

To conduct a test, a 2.3 m (7.5 ft) long by 1.1 m (3.5 ft) wide sheet of geotextile/geonet/geotextile composite (Gundnet) was centered and placed on the bottom surface of the tank. The Gundnet was cut smaller than the area of the tank to create a 75 mm (3 in.) wide space between the drainage material and edge of the tank to accommodate a bentonite seal (Fig. 4). The geotextile that separated the geonet from the GCLs was a 200 g/cm^2 (6 oz/sq yd), nonwoven geotextile with an apparent opening size of 0.15–0.25 mm.

Next, dry bentonite was placed in the space between the drainage material and the walls of the tank. A photograph of the seal and the drainage material is shown in Fig. 5. The GCL being tested was then placed over the drainage composite and bentonite edge seal, with the edges of the GCL either going to the edges of the steel tank (first test set) or within 25 mm (1 in.) of the edge of the tank (subsequent test sets). The spaces between the edges of the GCLs and the walls of the tank were filled with dry bentonite.

Next, a 300 or 600 mm (1 or 2 ft) thick layer of gravel was placed over the GCL with a front-end loader. The gravel had dry and saturated unit weights of 15.4 and 19.3 kN/m^3 (98 and 123 pcf), respectively, and a hydraulic conductivity of 5 cm/s (Estornell 1991). The tank was then slowly filled with water over a period of several days. The depth of water was then kept constant. The first set of tests was performed with a 300 mm (1 ft) thick gravel layer and 600 mm (2 ft) of water ponded on the GCLs. These conditions produced a calculated vertical effective stress of 3 kPa (0.4 psi) at the top of the GCL and 9 kPa (1.3 psi) at the bottom. The vertical effective stress was increased in the second and subsequent series of tests by increasing the thickness of gravel to 600 mm (2 ft) and decreasing the water depth to 300 mm (1 ft); the calculated effective stress acting on the top and bottom surface of the GCLs was 8 kPa (1.1 psi) and 10 kPa (1.5 psi), respectively.

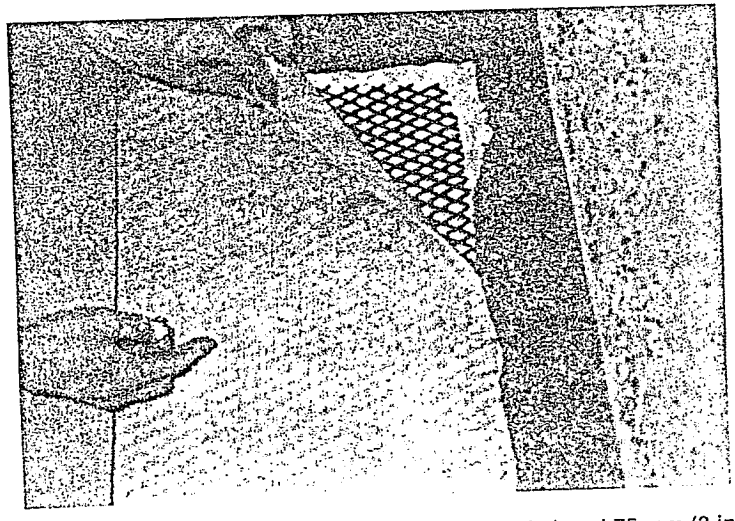

FIG. 5. Drainage Material (Geotextile/Geonet Composite) and 75 mm (3 in.) Wide Bentonitic Edge Seal

Page 81

G-3

Effluent water passing through the drainage hole was collected and weighed to determine the flux of water. Corrections were made to account for evaporation of water from collection pans. Tests were continued until the flux was steady. Except for Gundseal, steady flow was achieved after one to two and a half months, at which point outflow readings varied by no more than ±10%. For Gundseal, no outflow from any of the tanks occurred during more than five months of testing.

Hydraulic conductivity was calculated from Darcy's law for those GCLs that produced flow. It was assumed that the head loss was constant and that the pressure head was zero on the base of the GCL. The hydrated thicknesses of the GCLs (9.4 mm for Bentomat and 16–18 mm for Claymax), which were used to calculate hydraulic conductivity, were determined from laboratory swelling tests. Hydraulic gradient was typically in the range of 30–60.

Three types of tests were performed (Fig. 6). One type of test was a control test on individual sheets of GCL material that had no overlap. The second type of test was on overlapped sheets of GCL material. For Bentomat, sodium bentonite was placed along the overlap at the manufacturer's recommended rate, as shown in Fig. 7. Placement of Claymax overlaps is shown in Fig. 8. Placement of a Gundseal overlap is shown in Fig. 9 for the test with the HDPE facing upward.

At least one test was performed using the minimum overlap width rec-

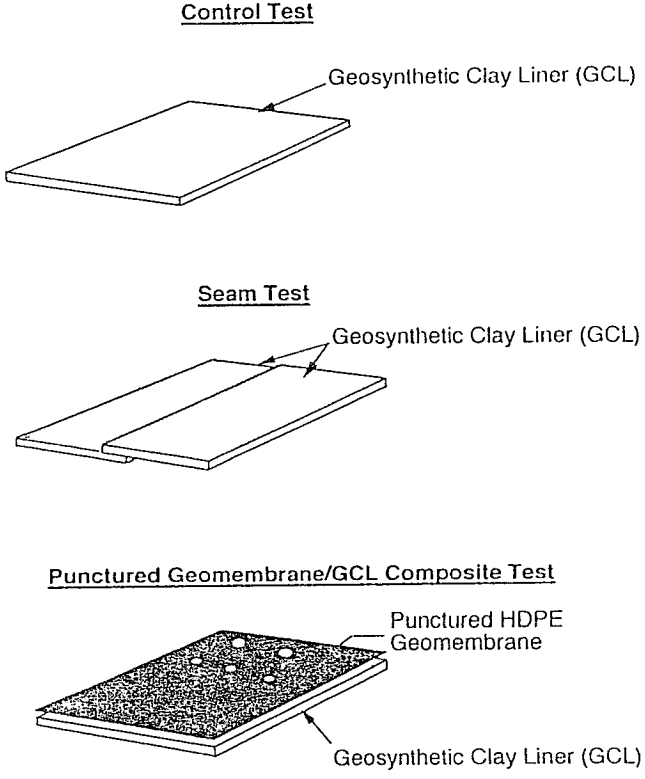

FIG. 6. Schematic Diagram of Types of Tests Performed in Tanks

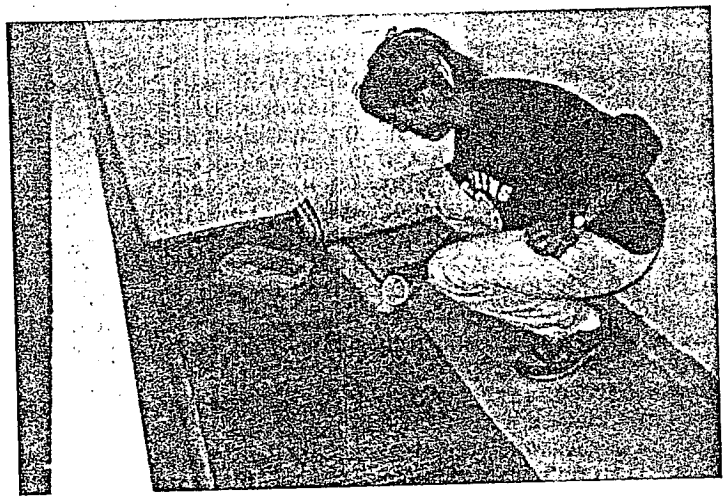

FIG. 7. Placement of Bentomat with Overlapped Seam (Note Spreading of Granular Bentonite along Overlapped Zone)

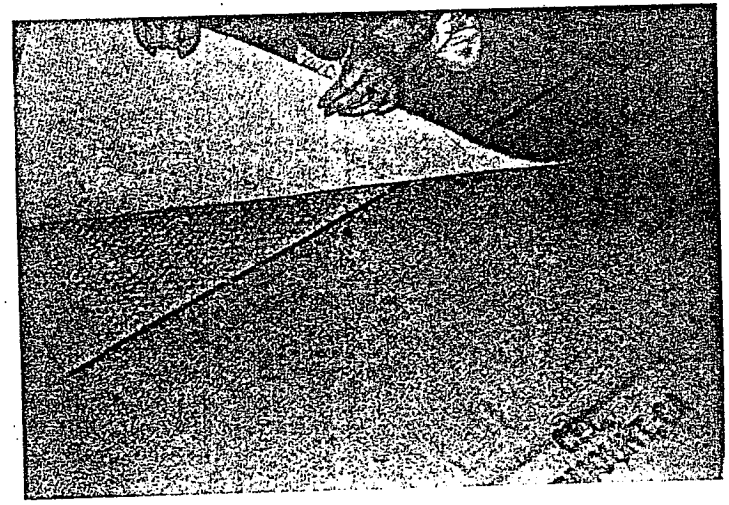

FIG. 8. Placement of Claymax with Overlapped Seam

ommended by the manufacturer [150 mm (6 in.) for Bentomat and Claymax, and 75 mm (3 in.) for Paraseal/Gundseal], and at least one test was conducted using half of the minimum recommended overlap width.

The third type of test (Fig. 6) involved a composite with the GCL overlain by a 1.5 mm (60 mil) HDPE geomembrane. Punctures that were made in the geomembrane included two 75 mm (3 in.) diameter holes, three 25 mm (1 in.) diameter holes, and three 600 mm (2 ft) long slits that were about 1 mm wide (Fig. 6).

Small-scale hydraulic conductivity tests were conducted on 100 mm (4 in.) diameter specimens. Flexible-wall permeameters were used, and pro-

Page 82

G-4

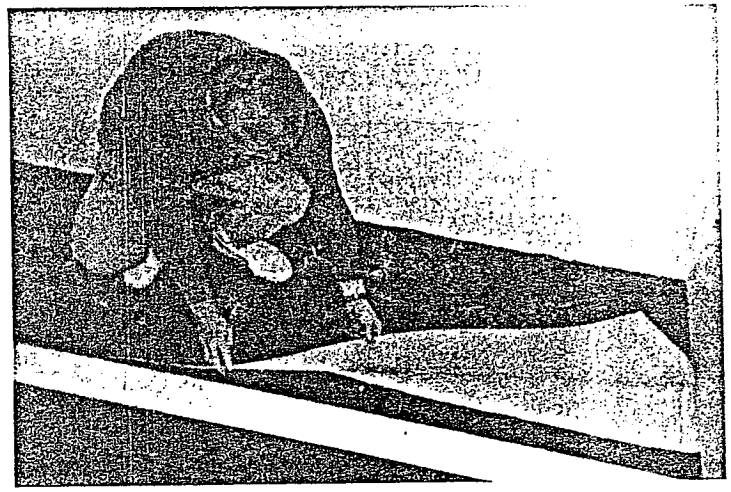

FIG. 9. Placement of Gundseal with Overlapped Seam

cedures outlined in ASTM method D5084 were generally followed. Only Bentomat was tested during this study. Tests on Claymax were performed by Shan (1990) and were not repeated. Hydraulic conductivity data for all the materials were obtained from sources cited in the next section.

Results of Laboratory Hydraulic Conductivity Tests

The results of flexible-wall hydraulic conductivity tests on the three geosynthetic clay liners are shown in Table 1 and Fig. 10. Hydraulic conductivities of all three GCLs were in the range of 3×10^{-10} to 6×10^{-9} cm/s. Hydraulic conductivity has a tendency to decrease with increasing effective stress. Individuals who compare hydraulic conductivities of different materials should be careful to compare values measured at the same maximum effective stress.

Results of Bench-Scale Tests

Bentomat and Claymax: Tests on Control and Overlapped Samples

Two control tests (no overlapped seam) were performed on 1.2 m by 2.4 m (4 ft by 8 ft) samples. Hydraulic conductivities are summarized in Table 2. The hydraulic conductivity of Claymax measured in the bench-scale tanks compared reasonably well with results of flexible-wall hydraulic conductivity tests performed on small test specimens at similar effective stress. However, with Bentomat, the hydraulic conductivity in the bench-scale tanks was about 10 times lower than values measured in flexible-wall permeameters.

Possible sources of error in the tests on Bentomat were considered. In flexible-wall permeability tests, problems were initially encountered with loss of bentonite near the edges during preparation of test specimens, which led to high flow rates near edges. The problem was minimized by hydrating an oversized test specimen, trimming the moist specimen, and smearing the edge of the test specimen with additional bentonite paste. Despite these procedures, the edge seal may still have been imperfect.

[a]Clay blanket underlain by Trevira 1135 geotextile filter.

In the tank tests on Bentomat, migration of bentonite out of the GCL and into the underlying materials may have reduced the flux of water through the GCL. When the first set of tests was dismantled, grey bentonite was visible in the geotextile/geonet/geotextile composite drainage material beneath both the Bentomat and the Claymax specimens. In the final series of tests, a thick, nonwoven geotextile was placed between the Bentomat and Claymax and the underlying Gundnet drainage composite. The geotextile was a Trevira 1135 fabric with a weight of 356 g/m^2 (10.5 oz/sq yd) and an apparent opening size of 0.13–0.21 mm. The thick geotextile filter stopped downward movement of bentonite from Bentomat and Claymax during the three-month testing period: bentonite could be seen on the upper surface of the geotextile filter but not in the bulk of the geotextile nor in the underlying drainage layer. However, with respect to the hydraulic conductivity anomalies, problems with bentonite migration were about the same for Bentomat and Claymax, and yet the comparison of results from tank tests and flexible-wall-permeameter tests was much different (Table 2). The writers were unable to isolate the cause for the discrepancy in hydraulic conductivity of Bentomat measured in flexible-wall permeameters and bench-scale tanks. Further investigation is recommended.

The results of tests on overlapped sheets of Bentomat and Claymax are summarized in Table 3. When the manufacturers' recommended minimum overlap width of 150 mm (6 in.) was maintained, the overall hydraulic conductivity of the overlapped panels was about the same as the hydraulic

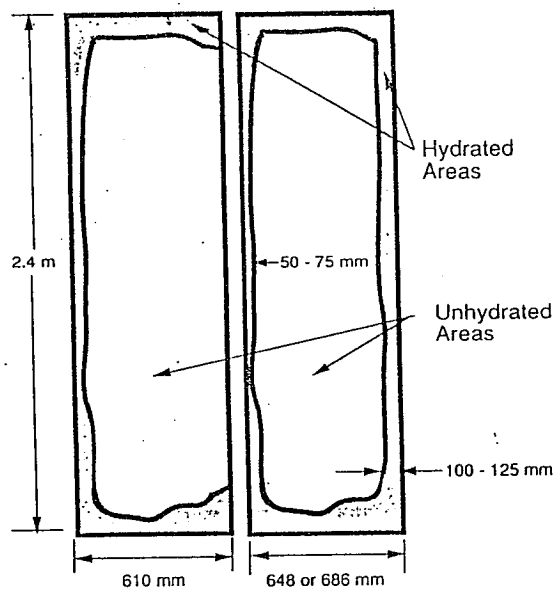

FIG. 11. Pattern of Wetting of Bentonite in Overlapped Gundseal when HDPE Faced Upward

conductivity of nonoverlapped, control panels. The GCLs self-sealed along the overlaps in these bench-scale tests.

When the overlap width for Claymax panels was reduced to half the minimum recommended value, the overall hydraulic conductivity of the overlapped panels was 1.2–9 times higher than the hydraulic conductivity of the control specimens, depending on the vertical stress applied to the specimens. For tests with effective stress greater than 7 kPa (1 psi), the performance of a narrow overlay of Claymax was better than for tests in which a lower effective stress was used. The differences between control and overlapped specimens may simply have been due to variations in the materials themselves; multiple tests for statistical purposes were infeasible due to the great time, effort, and expense associated with each of the tank tests. Intuitively, however, one would expect that the hydraulic integrity of the overlap might be more sensitive to the width of the overlap when the vertical stress is small. Overburden stress is probably needed for the Claymax seams to work because it appears that with little or no overburden, the bentonite simply expands unevenly when wetted and does not ooze through the openings of the geotextile and form a seal.

When the overlap width of Bentomat was reduced to half the minimum recommended value of 150 mm (6 in.), the hydraulic conductivity was 2.5 times greater than the value measured on the control sample with no overlap or the value measured on panels with the minimum 150-mm (6-in.) overlap (Table 3). Again, the difference may simply be the result of material variability. No tests were performed on Bentomat at the lower range of effective stress used for the first test series on Claymax.

Gundseal: Tests on Control and Overlapped Samples

Five tests were performed on Gundseal. In the first series, the HDPE geomembrane faced upward, the calculated effective stress was between 3

Page 84

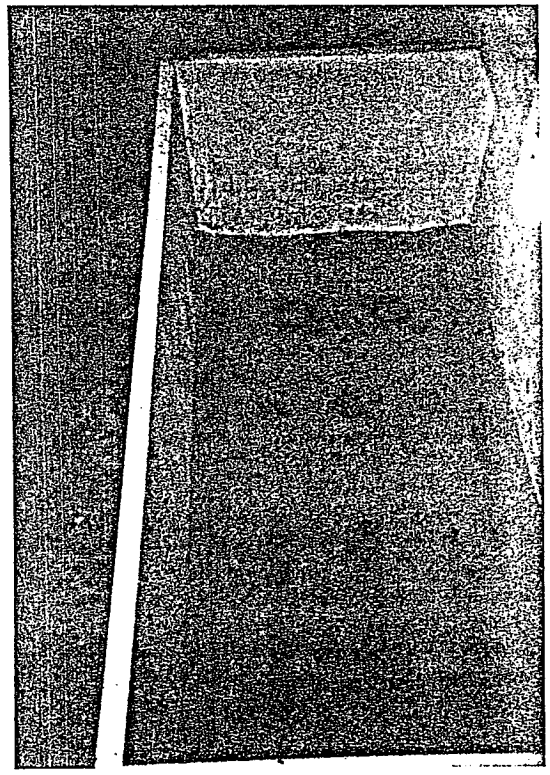

FIG. 12. Pattern of Wetting of Bentonite in Gundseal after Overlying Gravel and Punctured Geomembrane had been Removed from Tanks

TABLE 4. Results of Tests on Punctured Geomembrane/GCL Composites

Material (1)	Hydraulic Conductivity (cm/s)		Conductivity ratio: column 3 divided by column 2 (4)
	Control (no geomembrane) (2)	Composite (with punctured geomembrane) (3	
Bentomat	4×10^{-10}	6×10^{-10}	1.5
Claymax	7×10^{-9}	7×10^{-9}	1.0

and 9 kPa (0.4 and 1.3 psi), and the overlap widths were 75 mm (3 in.) and 38 mm (1.5 in.). A test on a control sample with no overlap was also performed. After five months of testing, no outflow was observed from any of the tanks. The tanks were dismantled, and it was found that the bentonite was wetted approximately 100–125 mm (4–5 in.) around the edges and 50–75 mm (2–3 in.) along the overlap (Fig. 11). Otherwise, the bentonite was not wetted. The tests on overlapped seams indicate that the minimum recommended overlap width contains a factor of safety under these test conditions.

In the second series, two tests were performed with the bentonite facing

upward. The calculated effective stress was between 8 and 10 kPa (1.1 and 1.5 psi), and the overlap width was 0 (control test) or 75 mm (3 in.). After five months, no outflow was detected. There was still some unhydrated bentonite in the overlapped areas at the end of the tests.

Composite GCL/Punctured Geomembrane

The puncture pattern in the geomembranes that were placed on top of the GCLs is shown in Fig. 2. Vertical effective stress varied from 8–10 kPa (1.1–1.4 psi), and a pressure head of 300 mm (1 ft) of water was maintained on the materials tested.

With Gundseal, water penetrated the bentonite at the defects, but water migrated < 75 mm (3 in.) from the defects over the five-month testing period (Fig. 12). Effective composite action was obvious: the bentonite sealed off defects in the geomembrane and the GCL prevented outflow of water from the punctured geomembrane/GCL composite.

With tests involving Bentomat and Claymax, outflow did occur. An apparent hydraulic conductivity was calculated, assuming one-dimensional flow through the entire cross-sectional area of the GCL; results are shown in Table 4. Hydraulic conductivities of the punctured geomembrane/GCL composites were about the same as those of the GCLs alone. When the tests were dismantled after about three months of permeation, it was found that the bentonite was fully hydrated over the entire area of the Bentomat and Claymax sheets. It is assumed that water flowed through the punctures in the geomembranes, spread laterally through the geotextile that separated the bentonite from the geomembrane, and soaked the GCL. Once the bentonite was wetted, the high in-plane transmissivity of the geotextile that separated the punctured geomembrane from the bentonite provided an avenue for water to spread laterally from the punctures and permeate the GCLs. However, in-plane transmissivity of geotextiles tends to decrease with increasing vertical stress; the vertical stress used in these tests was low.

Conclusions

Bench-scale hydraulic conductivity tests were performed on three geosynthetic clay liners (GCLs). The purpose of the tests was to determine: (1) Whether overlapped seams self-seal when the bentonite in the GCL is hydrated; and (2) whether the bentonite forms a seal against an overlying, punctured geomembrane. Conclusions drawn from this study are as follows:

1. The GCLs that were placed in large tanks self-sealed at overlaps when the bentonite was hydrated. Except for the case where low (< 7 kPa or 1 psi) vertical effective stress was employed, the hydraulic conductivities of overlapped materials were almost identical to values measured on control samples with no overlap.
2. For tests in which the minimum vertical effective stress was greater than 7 kPa (1 psi), the overlap width could be reduced as much as 50% below the minimum values recommended by the manufacturers without significantly increasing the overall hydraulic conductivity of overlapped panels. For the carefully controlled test conditions employed in this investigation, there was a factor of safety built into the manufacturers' minimum recommended overlap widths.
3. Bentonite was found to migrate vertically out of the two GCLs that contained bentonite between two geotextiles and into the underlying drainage layer when adequate filtration was not provided. Bentonite consistently migrated through a 200 g/m² (6 oz/sq yd), nonwoven, needle-punched geotextile with an apparent opening size of 0.15–0.25 mm and into an underlying geonet. However, bentonite migration was stopped during the three-month testing period by a 356 g/m² (10.5 oz/sq yd) nonwoven, needle-punched geotextile with an apparent opening size of 0.13–0.21 mm.
4. The effectiveness of composite action between a punctured geomembrane and the bentonite in the GCLs depended on whether a geotextile separated the punctured geomembrane from the bentonite. Good composite behavior was observed when the bentonite was in direct contact with the punctured geomembrane; liquid migrated laterally no more than about 75 mm (3 in.) from the punctures. Less effective composite action was observed when a geotextile separated the bentonite from the geomembrane.

Stress-Strain-Strength Responses of Compressible Chicago Glacial Clays

By Richard J. Finno,[1] Member ASCE, and Choong-Ki Chung[2]

ABSTRACT: The stress-strain-srength responses of compressible Chicago glacial clays are presented.These clays are lightly overconsolidated supra- or subglacial tills. Fixed piston and Shelby tube samples from various locations in the Chicago area were subjected to an extensive laboratory testing program, including index property, consolidation, direct shear, and K_o-consolidated, and undrained triaxial compression and extension tests. Results of the experimental program indicated the strengths of tills can be normalized when proper consideration is given to variations in natural water content. The different undrained strengths in compression and extension indicate that the clays exhibit stress-induced anisotropy. Initial undrained elastic moduli of the clays vary systematically with the overconsolidation ratio. Comparisons are made between strengths computed from relations based on normalized undrained strengths determined in the laboratory and those based on in-situ tests made at several locations. These data suggest that field vane strengths represent a conservative index of undrained shear strength for these Chicago clays.

Introduction

This paper describes the laboratory behavior of compressible Chicago glacial clays. These clays are low-to-medium plastic clays, which are typical of many deposits in the Great Lakes area (Wu 1958). There is a dearth of published information concerning the shearing properties of these clays, which is surprising given the extensive developoment of this area. This paper reviews the geology of the compressible clays, describes the experimental program, and presents the results of conventional index, consolidation, and shear tests, as well as K_o-consolidated undrained (CK_oU) triaxial compression (TXC) and extension (TXE) tests. Results of these triaxial tests are expressed in terms of normalized soil parameters. Undrained shear strengths based on these normalized soil parameters are compared to results of in-situ tests conducted at the two sites where most of the specimens were obtained.

Geology of Chicago Clays

The soils in the Chicago area are primarily glacially derived, and only the most recent advance of the continental glaciers left deposits in significant quantities. Bretz (1939) and Otto (1942) suggested that the soil was deposited in six fairly distinct till sheets during the Wisconsin stage of the Pleistocene epoch; in order of deposition, they are the Valparaiso, Tinley, Park Ridge, Deerfield, Blodgett, and Highland Park tills. Otto (1942) identified each till on the basis of water content and unconfined compression strength

point of compliance, C_p.

$$DAF = \frac{C_o}{C_p}$$

Therefore, if C_o is equivalent to 1, then with the calculation of the DAF, the predicted concentrations at the Point of Compliance will be dependent on the input leachate concentrations. The TWC has tabulated in Table 2 the recommended input concentrations for use in Multimed (or other fate and transport models) when site-specific-leachate data are not available. Values considered for recommended input concentrations were taken from USEPA's "Draft Background Document Summary of Data on Municipal Solid Waste Landfill Leachate Characteristics: July 1988, and the Toxicity Characteristic Leaching Procedure (TCLP) in 40 CFR §261.62. The greater of the values for each constituent is the recommended input concentration.

For concentrations used in the alternate design demonstration, the designer may:

1. Use the concentrations for the municipal solid waste landfills found in Table 2: or

2. Submit a proposal for a site characterization study for the alternate design.

Values in Table 2 will be revised as more leachate data become available. The designer should contact the TWC prior to commencing with design of a site to ensure the values listed are current or to obtain an updated list.

LEACHATE CHARACTERISTICS FOR MISSOURI SANITARY LANDFILLS

Lee D. Tharp, P.E.[1]

Abstract

Leachate management is a crucial issue that must be addressed during landfill design. To compile a detailed database of leachate chemical characteristics, the Missouri Department of Natural Resources (MDNR) ha in recent years required as permit conditions that sanitary landfills sample for and analyze semiannually certain metals and annually for hazardous waste characteristics, in accordance with 40 CFR Part 261. The original goal was to determine if sanitary landfill leachate is characteristically hazardous. The data indicates that it is not characteristically hazardous for the eight inorganic parameters specified in 40 CFR Part 261. The organic parameters required by TCLP for hazardous waste characterization are not included because of the lack of data.

Data from 13 sanitary landfills is provided with a total of 121 sampli events. One of the landfills is in the St. Louis area, although it is on the Illinois side of the Mississippi River. The sampling and analysis of the leachates were done by the individual landfills or the contracted private laboratories. The MDNR did not have requirements o laboratory QA/QC or sampling techniques. Data for two of the landfill was obtained from the local sewer district and was not a requirement o the individual landfill permits. All of the laboratory data is assume to be accurate, however it cannot be confirmed.

The data is presented along with ranges of values reported in the literature. For nearly all parameters the data is on the low side of the range reported in the literature. There is some question about wh methods should be used in sample preparation when analyzing for metals specifically with respect to filtering.

Introduction

Until the early 1970s land disposal of municipal solid waste was unregulated and uncontrolled in comparison to today's standards.

Memorandum

To: TCEQ

From: Cami A. Van Abel, SAIC

Subject: Appendix 3K, Attachment 1 – Site Characteristics and Monitoring Plan

Date: June 3, 2013

SAIC has reviewed the attached "Site Characterization and Monitoring Plan, McCombs Landfill, El Paso, Texas, October 11, 1993" and subsequent revision dated December 2012. The attached Report for the site characterization and monitoring references MSW Permit No. 729A throughout. It should be noted the attached report and data are applicable to the major permit amendment for MSW Permit No. 729B. Reference to MSW Permit No. 729A should be used synonymously with MSW Permit No. 729B.

EXECUTIVE SUMMARY

A hydrogeologic evaluation of the McCombs Sanitary Landfill was completed by SHB AGRA, Inc. (SHB) in 1993. The object of the evaluation was to develop a suitable groundwater monitoring plan at the subject site in order to comply with requirements set forth by the Texas Water Commission, now known as the Texas Commission on Environmental Quality (TCEQ), under Chapter 330 of the Texas Administrative Code. Parkhill, Smith & Cooper, Inc. and The Carel Corporation prepared modifications to comply with the 2006 revisions of Chapter 330.

The original evaluation program included a review of existing geotechnical, geological, hydrogeological and climatological data for the site. Groundwater data were obtained from federal, state and selected private entities. Details of daily operation were obtained from City of El Paso personnel familiar with the site.

Results of the SHB review indicate that the climate of the El Paso region is characterized by low average annual rainfall and high rates of evaporation. Groundwater is known to occur at depths exceeding 300 feet. These factors suggest an extremely low potential for leachate generation and migration to groundwater.

The original groundwater monitoring system consisted of the installation of three monitor wells at the facility. One located upgradient for background water quality determination, and two located downgradient to detect potential groundwater impacts based on regional groundwater flow direction data. A detailed Groundwater Sampling and Analysis Plan is included as a separate document.

The proposed groundwater monitoring system will be comprised of nine (9) monitoring wells: MW-1, MW-2, MW-3, MW-4, MW-5, MW-6, MW-7, MW-8, and MW-9. This will be done by retaining existing wells MW-1, MW-2, and MW-3, converting existing piezometers PZ-4 and PZ-5 to MW-4 and MW-5, and installing new wells MW-6, MW-7, MW-8, and MW-9. It is proposed that monitoring wells MW-6 through MW-9 be installed within 180 days of the approval date of this permit modification. Five (5) additional monitoring wells (MW-10, MW-11, MW-12, MW-13, and MW-14) may also be added to the facility groundwater monitoring system in the event the landfill constructs cells in Sectors B, C, D, and E.

1 INTRODUCTION

1.1 Background

This report presents the results of a hydrogeologic evaluation of the McCombs Landfill in El Paso, Texas. The purpose of the study was to characterize the operational history of this municipal landfill and to study the geotechnical and hydrogeologic conditions of the site vicinity in order to evaluate the potential for a leachate migration and develop a groundwater monitoring system that would meet Texas Commission on Environmental Quality (TCEQ) requirements.

The TCEQ, formerly known as the Texas Natural Resource Conservation Commission, adopted Subtitle D as published by the United States Environmental Protection Agency (EPA) relating to municipal landfills. As adopted, the regulations required the development of a groundwater monitoring program for large municipal landfills. The State of Texas required submission of a groundwater and/or leachate migration monitoring plan based on a hydrogeologic evaluation of the landfill prior to implementation. The monitoring plan was required for all municipal landfills unless specifically exempted by the TCEQ Executive Director. This monitoring plan includes details concerning the number and location of monitor wells for the facility, construction of the wells, sampling procedures and frequency, and target parameters for chemical analyses.

The City of El Paso (City) contracted SHB AGRA, Inc. (SHB) to evaluate site specific hydrogeological and geotechnical conditions and develop the original monitoring plan for submission to the TCEQ. Subsequently, the City retained Parkhill, Smith & Cooper, Inc. and The Carel Corporation to prepare modifications to the original monitoring plan to comply with the 2006 revisions of Chapter 330.

1.2 Purpose & Scope

The objective of this study is to develop a groundwater monitoring plan for the McCombs Landfill within the regulatory framework of the 2006 revisions to Chapter 330 of the Texas Administrative Code (TAC) by the State of Texas and the TCEQ. SHB originally reviewed available background data on the hydrogeologic characteristics of the site area and previous geotechnical investigations completed at the site during the permitting process. On-site conditions and waste disposal practices were further evaluated during a site reconnaissance. A groundwater monitoring program was developed based on regulatory requirements and estimates of the groundwater characteristics at the site.

1.3 Project Location & Landfill Description

The McCombs Landfill is located approximately 20 miles northeast of downtown El Paso in Section 6, Block 80, Township 1, Texas and Pacific Surveys. The landfill is situated at the northeast corner of the intersection of McCombs Road and Farm Road 2529 (see Figure 1). The permitted landfill area encompasses approximately 327 acres, although only a portion has been landfilled at present. The City is the Owner and operator of the facility.

The McCombs Landfill was originally permitted as a municipal solid waste landfill on August 13, 1976 under Permit No. 729 for operation on 25 acres. A permit amendment was issued on May 30, 1984, which increased the total permitted area from 25 acres to 327 acres; however, the site development details were only provided for approximately 70 additional acres (landfill cells, Phases I-III) at the time since a quarry operation was active on the remaining acreage to the north and east of the existing landfill and Phases I-III. In 2002 the permit was modified to comply with Subtitle D requirements and to provide the site development details and landfill capacity of the remaining acreage (landfill cells, Sectors A-G). The site development plan allowed for the sand and gravel quarry to continue operating, but the quarry is scheduled to move towards the south and eventually east as Sectors A-G are developed.

Sector A was constructed in 2003 and has been filled since that time. The landfill was placed in an inactive status effective February 3, 2005 with only limited waste being disposed of since that time from a City of El Paso clean up project. The City of El Paso intends to re-open the McCombs Landfill at a later date.

The McCombs Landfill currently uses an alternate liner design that was approved on July 10, 1995. The approved alternate liner consists of a single 60-mil geomembrane liner overlain by a 24-inch protective soil cover. A 60-mil geomembrane is constructed over a 6-inch compacted caliche layer. This alternate liner design supercedes a previous alternative liner design (consisting of a double geomembrane liner separate by a geonet [leachate detection layer] and overlain by 24-inch leach collection system/protective cover with a minimum hydraulic conductivity of 1x10-2 cm/sec) that was approved on October 19, 1994. Landfill cells constructed prior to this time are presumably un-lined. The depth of the landfill cells at this facility are estimated to be approximately 40 to 50 feet deep. The elevation of the liner for Sectors A-G at the lowest points (leachate collection sumps) is approximately 4017 feet mean sea level (City Datum).

2 ASSESSMENT

2.1 Overview & Limitations

The scope of this project was limited to the review and analysis of available data for the McCombs Landfill. The discussions and recommendations of SHB are based on geotechnical, geological and hydrogeological conditions at the site, as described in published literature and available well records. No additional field exploration and/or testing was completed during this phase of the project. Based on past site history, climatological records, expected soil conditions and depth to groundwater, it appears very unlikely that leachate will impact groundwater. Locations for existing groundwater monitoring wells were selected on the basis of groundwater flow directions published in reviewed literature and evaluation of well data. After installation of monitor wells was complete, actual groundwater measurements on site indicated differing groundwater flow directions, necessitating installation of additional wells.

These and related limitations associated with the interpretation of results and data provided by other independent entities should be recognized in evaluating discussions and recommendations presented herein.

2.2 Regulatory Review

The TCEQ implemented new 30 TAC 330 Subchapter J rules governing groundwater monitoring and corrective action in 2006 (effective March 26, 2006). Per 30 TAC §330.401(b) *owners and operators of landfill units shall comply with the 2006 Revisions to this subchapter* [Subchapter J] *by applying for a permit modification with public notice in accordance with §305.70(l) of this title (relating to Municipal Solid Waste Permit and Registration Modifications) to revise any inconsistent provisions within two years from the effective date of the 2006 Revisions.* This plan has been modified to satisfy 30 TAC §330.403(a)(2), which states: *The point of compliance monitoring system must include monitoring wells installed to allow determination of the quality of groundwater passing the point of compliance as defined in §330.3 of this title and to ensure the detection of groundwater contamination in the uppermost aquifer. Monitoring well spacing for a municipal solid waste landfill unit shall not exceed 600 feet without an applicable site-specific technical demonstration that may be supplemented with a multi-dimensional fate and transport numerical flow model as set forth in subsection (e) of this section. The owner or operator of a municipal solid waste landfill unit must install a groundwater monitoring system at the point of compliance, as required by 40 Code of Federal Regulations §258.51(a)(2). When physical obstacles preclude installation of the groundwater monitoring wells at existing units,*

the wells may be installed at the closest practicable distance to the point of compliance as defined in §330.3 of this title that will ensure detection of groundwater contamination of the uppermost aquifer.

2.3 Review & Analysis of Available Data

Available information concerning the history of landfilling at the site, regional and local geology and hydrogeology was obtained and reviewed by SHB. The pertinent information is summarized in Section 4. Sources included federal, state and local agencies, as well as readily available private sector studies pertaining to local conditions and landfill operations in general. Information collected included:

- A time-lapse series of aerial photographs spanning the time from before commencement of landfilling operations at the site to the present.
- Site investigative report compiled by Danny R. Anderson Consultants (DRA), presented as part of the permit application in January, 1984 (DRA, 1984).[1]
- Documentation of permitting, inspection reporting and correspondence concerning landfilling operations received from the TDHR and the TCEQ.
- Published geologic and hydrogeologic mapping and literature available from public agencies and private/professional sources.
- Subtitle D section applicable to municipal landfills as outlined by the EPA, and the TCEQ's interpretation of the same (TAC Chapter 330).
- Data on water wells located within about 2 miles of the landfill site obtained from the Texas Water Development Board (TWDB), the TCEQ, and New Mexico State Engineers Office and the Interstate Stream Commission in New Mexico. This information included well location maps, water uses, depths to groundwater, well depths, well owners and drillers logs.
- Additional groundwater information was obtained from the Public Service Board (PSB), and the El Paso Water Utilities (EPWU).

Parkhill, Smith & Cooper, Inc. and The Carel Corporation reviewed additional data as part of the 2007 and 2012 modifications to this report. The new data from groundwater monitoring wells, groundwater contour maps, and groundwater sampling events is discussed in Section 4.7.

[1] References are listed at the end of this report.

2.4 Field Reconnaissance

SHB personnel completed multiple site visits during May, 1993. During the site reconnaissance, observations were made of site conditions, landfill operations, environmental conditions and general land use. Visible geologic, hydrogeologic and geotechnical conditions were studied in the open pit exposures. Groundwater wells and lysimeters on site were also visually located. Buildings, fenced areas, vegetation and land use on and around the subject site were also noted.

Parkhill, Smith & Cooper, Inc. and The Carel Corporation performed a site visit on July 16, 2007. During that reconnaissance, observations were made of current site conditions, on-site aggregate mining operations, water supply wells in the vicinity of the site and monitor wells located at the sludge disposal site, which is owned and operated by El Paso Water Utilities, located west of McCombs Road.

2.5 Groundwater Wells

Available information regarding groundwater wells in the site vicinity was originally reviewed and analyzed by SHB. Well information from TCEQ files was collected for wells located within a two-mile radius of the project site by Agency Information Consultants (AIC, 1993). Additional data was collected from El Paso Water Utilities (EPWU) and the New Mexico State Engineers Office (NMSEO). Many of the water wells in the project vicinity are EPWU public water supply and recharge wells. Groundwater flow maps and hydrographs of selected wells were constructed in an effort to analyze hydrologic conditions in the area. Regional hydrologic conditions and local well data are further discussed in Sections 4.5 and 4.6, respectively. Site-specific groundwater information in provided in Section 4.7.

3 REVIEW OF PREVIOUS INVESTIGATION

The initial permit application for the McCombs Landfill was completed by DRA on behalf of the City. The permit application addresses site characteristics, and includes discussions of the types of wastes to be accepted, and presents pertinent operational and maintenance criteria. Subsurface investigations completed on site were presented in a report that was appended to the permit application.

Certain limitations exist in the interpretation of results and data provided by other independent entities.

3.1 Geotechnical Investigation Data

This section primarily focuses on the subsurface investigations and the geotechnical profile of the soils underlying the site as described by DRA (1984).

- **Subsurface Drilling:** DRA completed 8 test borings west of the then existing landfill between September, 1982 and January, 1983, to depths between 30 and 50 feet below existing grades. Fifteen additional borings were drilled to 60 feet at locations to the east and north of the landfill. All drilling by DRA was completed using a Mobile B-52/61 and 8-inch diameter hollow stem auger. The geotechnical investigation report prepared by DRA also includes logs of 6 borings previously completed by Dickenson Laboratories to depths of 50 feet north of the landfill.

- **Geotechnical Profile:** The original 8 borings completed by DRA were drilled within an existing sand and gravel pit. The soils encountered predominantly were relatively clean sands, interbedded with lesser amounts of silty sands and occasional layers of clayey sands and sandy clays. Relatively clean sands with varying silt and gravel contents were noted in the 15 additional borings completed by DRA. The surface elevations of these 15 borings is unknown. In the 6 borings drilled by Dickenson, clayey sands were encountered to depths ranging between 13 and 25 feet, underlain by relatively clean sands. In one of the 6 borings, however, clean sands were encountered for the entire depth of the boring.

  In general, the relatively clean and silty sands are non-plastic, while the clayey soils range from low to high in plasticity. No groundwater was reported in any of the borings drilled. Permeability tests were not considered necessary, based on the soil types encountered. DRA estimated a coefficient of permeability to be between 0.01 and 0.04 cm/sec.

The report includes recommendations for temporary and permanent slopes, and for fill material to be used for site grading. Recommendations and specifications for other earthwork elements of the project were also addressed.

3.2 Permit Application Data

Pertinent information, including site characteristics and solid waste data was provided along with the permit application. Design criteria such as engineering considerations, land use, ground and surface water protection, etc. were also addressed. This information is briefly summarized below:

- **Solid Waste Data:** The landfill was located to serve the northeast parts of El Paso with an estimated population of approximately 77,500. The facility was designed to accept approximately 162 tons of non-hazardous industrial, municipal, commercial and domestic waste per day. Based on current estimates however, the landfill accepts about 220 tons of domestic waste per day. City personnel have indicated that the landfill does not accept industrial or commercial waste.

- **Site Location & Land Use:** The location of the site was defined as "...approximately 20 miles northeast of downtown El Paso in Section 6, Block 80, Township 1." Land use within a one mile radius included the existing landfill, a sand quarry, and some commercial operations. The nearest airfield reportedly was a privately owned sail plane airfield located approximately 2.3 miles from the site. The report states that "...an Eastern Boundary Fault Zone exists between the Franklin Mountains and the Hueco Bolson deposits.", and "...assuming continuous movement this (movement of the fault) would equate to approximately 0.005 inches per year" (DRA, 1984).

- **Groundwater Protection:** According to the DRA report attached to the permit application, unconfined groundwater occurs beneath the land surface of the Hueco Bolson at depths ranging between 260 and 360 feet. The water table reportedly has a hydraulic gradient of about 0.025 "...toward a major cone of depression in the vicinity of the El Paso International Airport." The report states that there is a steady increase in the total dissolved solids (TDS) with increasing depth. An inventory of existing water wells in the vicinity of the site also was completed.

  According the DRA report, the landfill would not pose a significant risk to groundwater underlying the site. The report states that "...soil moisture storage is always below available water holding capacity so gravity percolation is impossible." The report further states that the cemented soils and clay lenses underlying the site will also inhibit downward movement of leachate generated in the landfill units. The report points out that the then existing landfill had not caused a deterioration in groundwater quality, since important constituents from landfill leachate including BOD, COD, iron, manganese, chlorides, nitrates, hardness and trace elements were not detected in the wells located downgradient from the site.

- **Miscellaneous Information:** The DRA report addressed other subjects such as daily operational procedures, utility corridors within the site, surface water issues, and controlling methane generated in the landfill units. Discussions of site access were also included. These points are not further discussed herein.

4 SITE CONDITIONS & HISTORY

4.1 Site History

Available historical information was originally reviewed by SHB to assist in evaluating conditions on and in the vicinity of the site. The review included a brief evaluation of prior site usage. Particular attention was paid to past and current landfilling operations. Information reviewed included data available from federal, state, city and private agencies. Persons familiar with the site and landfilling operations were contacted for additional site information. Additional site history information has since been provided by the City of El Paso.

Prior to landfilling operations, the site was owned by Prices Producer, Inc. The City of El Paso purchased the property from Prices in September, 1954. The site was subsequently leased to El Paso Sand Products Inc. to be used for aggregate mining and was later leased to Jobe Concrete Products. Quarrying operations continued to date on site through a lease with Cemex.

The McCombs Landfill was first permitted as a Type I landfill by the Texas Department of Health Resources (TDHR) in August, 1976. According to City personnel, landfilling operations commenced in 1960. This initial permit was issued in 1976 for an area of 25 acres and a waste volume of approximately 400 tons per day. In May, 1984, the permit was amended to cover a total area of approximately 327 acres.

4.2 Climate

Weather information was collected from the National Oceanic and Atmospheric Administration (NOAA, 1993) by SHB. Based on this information, the climate of the El Paso region is characterized by an abundance of sunshine throughout the year, high daytime temperatures with very low humidity, scanty rainfall, and a relatively mild winter season typical of arid areas at low latitudes. Summer temperatures are high, frequently above 90 degrees and occasionally above 100 degrees. Humidity generally ranges between 10 and 25 percent. Winter daytime temperatures are mild, rising to 55 to 60 degrees on the average.

Rainfall throughout the year is light and generally insufficient for any plant growth except desert vegetation. Most of the precipitation occurs between July and September, from short but heavy thunderstorms. Small amounts of snowfall occur almost every year, but accumulations rarely exceed one inch, and snow seldom remains on the ground for more than a few hours. Average annual rainfall and snowfall are approximately 8.5 and 5.2 inches, respectively. Total annual precipitation varies from approximately 8 to 12 inches per year.

Wind velocities are not excessively high. Prevailing winds are from the north in the winter and south in summer, with the prevailing direction for the year north by a small margin.

4.3 Topography

The original topography of the site was presumably hilly. However, subsequent quarrying and landfilling operations have significantly modified the natural contours of the site. The present topography is now dominated by large depressions which are remnants of the old quarrying operations. These excavations range up to 50 feet in depth. The elevated landfilled areas are built-up to elevations in excess of 50 feet above grade. Earthen berms surrounding the landfill reduce the potential for run-on from adjacent properties.

4.4 Geologic Setting & Soil Profile

The McCombs Landfill lies within the Rio Grande Rift portion of the Mexican Highlands section of the Basin and Range Physiographic Province (Fenneman, 1931; Thornbury, 1965). Thornbury (1965) defines the Mexican Highlands Section as an area of variable geologic structure characterized by high desert valleys and mountain ranges. Hawley (1975) subdivided the Mexican Highlands Section into the Bolson and Rio Grande subsections. The Bolson Subsection covers a large area of southwestern New Mexico and portions of Texas, Chihuahua, Mexico and Arizona. This region is characterized by broad intermontane basins with internal drainage, called bolsons, that are bounded by fault-block mountain ranges.

The mountain ranges on the eastern side of the Bolson subsection trend in a general north-to-northwest direction and typically flank sizeable basins, including the Hueco Bolson in which the site is located (Thornbury, 1965). The Rio Grande Valley is incised into thick deposits of basin fill at the southern end of the Hueco Bolson typically ranging in age from Pliocene to Holocene. A broad alluvial plain with gently sloping terraces characterizes the valley of the Rio Grande River.

Tectonic adjustment initiating basin formation began in the region in the early Miocene. As the basins developed, erosion and subsequent deposition of Santa Fe Group sediments occurred (Gile and others, 1981; Strain, 1966). Renewed faulting in Late Miocene and Pliocene time, coupled with continued relative uplift, produced a series of en echelon grabens, such as the Mesilla and Hueco Bolsons, that characterize this section of the Rio Grande Rift Valley. These bolsons

regionally have received several thousand feet of sediments during the Late Cenozoic (Strain, 1966).

Basin fill was initially derived from the surrounding mountains. During the Pleistocene, the ancestral Rio Grande River flowed into closed basins in the area depositing thick sequences of sediments and forming an ephemeral lake (Strain, 1969). This basin fill has been correlated with similar deposits in other sections of the Rio Grande Rift and is named the Santa Fe Group by Hawley and others (1969). It has been proposed that the sediments of the Hueco Bolson be included in the Santa Fe Group, based on similar composition and depositional history.

The Hueco Bolson deposits have been divided into two rock stratigraphic units by Strain (1966), the Fort Hancock Formation and the Camp Rice Formation. The older Fort Hancock Formation is a massive unit composed of poorly consolidated clays, silts and fine grained sands ranging in color from grayish red to brown (Strain, 1966, 1980). The persistent and essentially horizontal bedding and fine texture of the Fort Hancock Formation indicates that it was deposited in lacustrine and playa environments. Goebel and others (1987) hypothesized deposition of the Fort Hancock Formation on a low-relief basin floor with a highly sinuous meandering river and ephemeral lakes.

In early Pleistocene time, adjacent basins had aggraded to levels sufficient to coalesce with the Hueco Bolson. Periods of moderately high precipitation resulted in the formation of a large ephemeral lake system which Strain (1966) named Lake Cabeza de Vaca. This ancient lake covered an area from Mesilla Bolson, more than 50 miles northwest of the site, to the Red Light Bolson, south of Sierra Blanca.

Deposition of fine grained sediments in the Hueco Bolson continued until an outlet to the southeast formed in early Pleistocene time. This outlet essentially breached Lake Cabeza de Vaca and changed the depositional environmental from predominantly lacustrine to fluvial (Strain, 1980). The Camp Rice Formation (Strain, 1966) records continued fluvial aggradation by the ancestral Rio Grande River in the Hueco Bolson.

The Camp Rice Formation unconformably overlies the Fort Hancock Formation. It is primarily composed of gravel, sand, silt and occasional discontinuous lenses of volcanic ash. Its color varies from very light gray to shades of pink, orange and light brown. The Camp Rice Formation is composed of two basic subdivisions, a fluvial and a piedmont facies (Gile and others, 1981). The fluvial facies is chiefly sandy to pebbly river-channel deposits with subordinate fine-grained overbank units. This facies thickens toward the bolson axes and commonly wedges out against the piedmont facies. The permitted area is probably underlain by fluvial deposits of the Camp Rice Formation (Seager and others, 1987).

Termination of Camp Rice deposition probably occurred as a result of spillover from the upper reaches of the Rio Grande River or stream capture by an arroyo system draining the Hueco Bolson. The upper reach of the Rio Grande River in the Mesilla Bolson was thus joined to the Rio Conchos through El Paso Canyon in mid-Pleistocene time (Strain 1970; Hawley and

Kottlowski, 1969). Integration of the upstream and downstream reaches of the Rio Grande River, re-establishing through-flowing drainage, was apparently the major cause of subsequent valley incision (Johnson and others, 1984).

The timing of this key shift from basin aggradation to incision is not precisely known, but can be estimated reasonably well from dated units within and overlying the Camp Rice Formation, and from subsequent development of geomorphic surfaces and soils (Gile and others, 1981; Machette, 1985). After the establishment of an integrated Rio Grande in mid-Pleistocene time, large-scale aggradation of the bolsons ceased. Several cycles of accelerated river downcutting followed, separated by periods of relative stability. This Quaternary history is expressed morphologically as a series of terrace, alluvial fan and pediment surfaces cut into or deposited upon the Santa Fe Group (Kottlowski, 1958). These surfaces are locally modified by recent sand deposits.

Numerous fault scarps of Quaternary age are present in the Hueco Bolson near the landfill. One inferred scarp apparently traverses the northeastern quadrant of the landfill permit area (SHB, 1993). This fault was not identified on the geologic map prepared by Harbour (1972). Insufficient information is available to confirm or refute the presence of a fault. Other north-south trending scarps are also apparent in the area. The age of faulting in Hueco Bolson has been dated as less than 0.5 m.y., based on offset in the Camp Rice Formation and in soils formed on the Camp Rice Formation (Seager, 1980). More precise dating of the faults has not been performed.

As noted previously, the McCombs Landfill is located on deposits of the Hueco Bolson, probably Camp Rice Formation. These deposits primarily consist of clay, sand and gravel, with some caliche (Bureau of Economic Geology, 1983). The landfill site is underlain by Tertiary and Quaternary basin (bolson) deposits, overlain by areas of gravel and caliche rimrock as presented in Figure 3 (Harbour, 1972). Recent Quaternary alluvial deposits are also present in the landfill vicinity in topographically low areas.

The caliche rimrock of Pleistocene age is commonly two to four feet thick, and consists of angular fragments of bedrock derived from the mountains and cemented by white caliche. The bolson deposits in the area were described by Harbour (1972) as "friable white sand with rounded volcanic pebbles". Bolson deposits of clay and sand with some gravel and caliche have been observed in water wells drilled east of the Franklin Mountains. The bolson deposits have been documented to extend to a depth of at least 4,920 feet below ground surface in a well drilled south of Newman, New Mexico, approximately five miles east of the landfill (Harbour, 1972).

A soil investigation was performed in 1983 by DRA. During the investigation, numerous soil borings were drilled on site to a depth of 60 feet below ground surface. According to boring logs generated during the investigation, the soils consist of an upper zone of variable thickness of silty sand, underlain by deposits of clean and gravelly sands. Stringers of clay which did not appear to be laterally extensive were observed in some of the soil borings. The sands and gravelly sands appear to be lenticular in nature, with little correlation across the site.

4.5 Regional Hydrogeology

Published information on the hydrogeology of the site area was reviewed to evaluate the factors influencing the groundwater system at the site. The regional groundwater system in the area primarily consists of the Hueco Bolson aquifers.

The Hueco Bolson has been divided into the City Artesian area, the Mesa area and the Lower Valley (Leggat, 1962). The City Artesian area underlies downtown El Paso and east El Paso as far as Ysleta. The Mesa area extends north of the City Artesian area into New Mexico and east to the Hueco Mountains. The Lower Valley area parallels the Rio Grande, and extends from Ysleta to beyond Tornillo. The McCombs Landfill is located in the Mesa area.

In general, the groundwater regimes of the City Artesian and the Lower Valley areas are essentially the same. Two aquifers occur in these areas: an upper aquifer in the Rio Grande alluvium and a lower aquifer in the Hueco Bolson deposits. Since no known impermeable zone of regional extent separates these aquifers, the Rio Grande alluvium and the Hueco Bolson are considered to be, at least in part, hydrologically connected in the City Artesian and Lower Valley areas (Alvarez and Buckner, 1980). Increased pumpage from public supply wells and lining of a portion of the Rio Grande River in the City Artesian area have affected the recharge-discharge relationships, and caused fluctuations in the direction of groundwater flow. In the Lower Valley area, recharge occurs from the Rio Grande Alluvial aquifer into the Hueco Bolson during times when the water level in the river is high, and from the Hueco Bolson into the Rio Grande alluvium when the water level in the river is lower.

The Mesa area primarily consists of Hueco Bolson deposits. Historic withdrawals of groundwater since 1906 for public water supply and irrigation have caused major declines in the water level. The average water level decline in the Hueco Bolson from 1903 to 1980 is approximately 53 feet (White, 1987).

Locally, recharge to the aquifer occurs due to mountain front infiltration of precipitation from the surface and from the injection of treated sewage into the aquifer from the Hueco Bolson Recharge Project (White and Sladek, 1990). Numerous injection wells have been constructed northeast of El Paso and water from the Fred Hervey Water Treatment Plant has been injected into the aquifer by El Paso Water Utilities (EPWU) since the mid-1980s. Over one billion gallons of treated water per year were injected into the Hueco Bolson between 1986 and 1991. The reinjection resulted in mounding of groundwater in the recharge project area, and has caused

some change in the groundwater flow regime. A slight mounding effect from the recharge project was observed on the EPWU 1993 Water Table Contour Map (EPWU, 1993). Since 1991, EPWU has been selling the reclaimed water to customers; thus, less water has been injected into the aquifer (Sperka, 1993) (Solis-Rojas, 2009). As of June 2009, over 60% of the reclaimed water produced at the Hervey Plant is sold to customers by the EPWU (Solis-Rojas, 2009). Selling the reclaimed water has produced a decline on water available for aquifer recharge. The recharge well nearest to the landfill is well RW11, located approximately one mile southwest of the landfill near well 49-05-214 (Solis-Rojas, 2009).

Based on available information regional groundwater flow in the McCombs Landfill area is generally to the south-southeast. However, more recent data indicates that site-specific groundwater flow is easterly as discussed in Section 4.7. Groundwater movement in the area is generally less than 1.0 feet per day (White, 1987). EPWU groundwater data indicate that the static groundwater elevation in the area is between 3670 and 3675 feet above mean sea level (msl), or approximately 370 to 390 feet below ground surface (EPWU, 1993). No evidence of perched aquifers in the area was noted during our research.

The Hueco Bolson generally contains fresh water in its upper portion and becomes saline at depth (Davis and Leggat, 1965). Groundwater quality in the landfill area is variable, with total dissolved solids (TDS) contents ranging from less than 500 ppm to greater than 1000 ppm (White, 1987). A localized plume of groundwater exhibiting elevated TDS and high nitrate values was observed in the vicinity of the former Price's Dairy Farm during the 1960s and 1970s. The Dairy was located approximately ¾-mile southwest of the permitted area. The plume probably occurred due to the leaching of salts into groundwater during excessive irrigation of crops in the area from 1956 to 1974 (White, 1987). Injection of high quality water from the Hueco Bolson Recharge Project has essentially diluted and dissipated the plume (Sperka, 1993).

4.6 Local Well Data

There are 41 wells located within the two-mile study area of the McCombs Landfill site according to well registration reports. The locations of the wells are shown in Figure 4. Available detailed well logs are presented in Appendix A. The wells range in total depth from 104 to 1483 feet below the local ground surface. Most of the wells are registered for public supply or industrial use. The registered wells were completed between 1940 to 2007.

Well records reviewed by SHB showed a wide range of measured groundwater depths. The variation in the recorded depths appears to be primarily due to the wide variation in measurement dates. Wells with earlier completion dates generally indicate shallower water depths than wells constructed at later dates. The location of the wells relative to the local recharge and pumping depression zones also affects the measured water depths. The recorded depth to water in the wells range from 296.6 to 385 feet below the ground surface (bgs). Depths to water in two original water wells for the quarry operations located directly west of the site were measured at 361 and 385 feet bgs. General contouring of the regional water table by SHB, considering time of measurements, is presented in Figures 5 through 8. Based on that information, groundwater

flow was originally believed to be southerly as illustrated in Figure 9. However, site specific water level data subsequently collected indicates that groundwater flow is easterly. Hydrographs of selected wells indicate a groundwater level decline in the area of approximately 20 feet in the past 20 years (Figures 10 through 13).

The nearest water wells currently used for public water supply are State Well Numbers JL-49-05-301 and JL-49-05-303 (EPWU wells 42 and 53, respectively) (Sperka, 1993). Well 303 is located approximately 1/2-mile southeast of the landfill and well 301 is located about 2/3-mile south of the site. Two wells are currently present directly adjacent to the site, State Well Numbers JL-49-05-315 located to the west and another well (CEMEX) whose State Well Number is unknown is located to the south. Both wells are owned and used by Cemex for quarrying operations. A former well, JL-49-05-314, was also located directly west of the site and was plugged and abandoned October 17, 2007. A copy of the plugging report is included in Appendix A.

4.7 Site Specific Groundwater Data

Supplemental site-specific hydrogeologic information was obtained and reviewed by Parkhill, Smith & Cooper, Inc. and The Carel Corporation. The supplemental information includes:

- The 2003 Groundwater Monitoring Well Installation Report by Raba Kistner. The aforementioned report details the installation activities for groundwater monitoring wells MW-1, MW-2, and MW-3.
- The geophysical logs for groundwater monitoring wells MW-1, MW-2, and MW-3 and El Paso Water Utilities wells EPWU-1, EPWU-2, EPWU-3.
- Water-level measurements were collected from groundwater monitoring wells MW-1, MW-2, and MW-3 from September 2003 to November 2007 by the City of El Paso.
- Water-level measurements from four (4) proximal groundwater monitoring wells collected by the City of El Paso in July and November 2007. The four (4) proximal groundwater monitoring wells were wells EPWU-1, EPWU-2, EPWU-3, and EPWU-4A.
- Well completion information for a water well (CEMEX) installed near the southeast corner of the site in the Spring 2007.
- Groundwater Monitoring Reports from June 2004 to July 2007.

4.7.1 Existing Groundwater Monitoring Wells

The existing groundwater monitoring system is comprised of monitor wells MW-1, MW-2, and

MW-3 and is illustrated in Figure 2. The boring logs for MW-1, MW-2, and MW-3 indicate the subsurface sediments are primarily composed of sand with some interbedded clay lenses and gravels. Most sands above a depth of 350 feet are described as being coarse grained and poorly sorted. Medium grained and fine grained sands appear to become more prevalent below 350 feet. The lower value of coefficient of permeability provided by Anderson (1983) is believed to be applicable to the medium and fine grained sands in the screen intervals.

The existing monitor wells have been constructed in accordance with 30 TAC §330.242, Monitor Well Construction Specifications. The logs and construction details of monitor wells MW-1 through MW-3 are provided in a December 18, 2003 Groundwater Monitoring System Installation Report by Raba Kistner (see Appendix B). Geophysical logs were also completed in monitor wells MW-1 through MW-3. The said geophysical logs are also provided in Appendix B.

4.7.2 September 2003 – July 2007 Water-Level Measurements

Water-levels were measured in wells MW-1, MW-2, and MW-3 from September 2003 to July 2007 by the City of El Paso. The recorded groundwater measurements are shown in the table below. Groundwater contour maps from September 2003 to July 2007 are provided in Appendix C.

Water-Level Measurements

Monitor Well	MW-1		MW-2		MW-3	
Top of Casing Elevation, ft msl	*4070.23*		*4083.89*		*4076.70*	
Total Well Depth from Top of Casing, ft	475.88		500.83		498.02	
Measurement Date	**WATER LEVEL DEPTH (FT) / *ELEVATION (FT MSL)***					
9/5/2003	396.15	*3674.08*	400.27	*3683.62*	397.71	*3678.99*
11/14/2003	396.29	*3673.94*	399.89	*3684.00*	391.52	*3685.18*
11/18/2003	396.03	*3674.20*	399.87	*3684.02*	391.25	*3685.45*
5/12/04 - 5/13/04	393.60	*3676.63*	400.58	*3683.31*	389.60	*3687.10*
9/27/04 - 9/28/04	394.10	*3676.13*	387.20	*3696.69*	390.00	*3686.70*
12/28/2004	394.10	*3676.13*	387.20	*3696.69*	390.00	*3686.70*
3/30/2005	393.00	*3677.23*	399.10	*3684.79*	389.10	*3687.60*
1/10/2006	393.40	*3676.83*	397.80	*3686.09*	388.90	*3687.80*
4/5/06-4/8/06	393.80	*3676.43*	397.70	*3686.19*	389.30	*3687.40*
7/20/2006	393.85	*3676.38*	399.02	*3684.87*	389.51	*3687.19*
10/31/06 - 11/2/06	394.65	*3675.58*	399.35	*3684.54*	390.45	*3686.25*
4/17/2007	394.30	*3675.93*	400.20	*3683.69*	389.90	*3686.80*
5/21/2007	394.10	*3676.13*	399.60	*3684.29*	389.50	*3687.20*
7/25/2007	394.10	*3676.13*	399.55	*3684.34*	389.70	*3687.00*
11/9/2007	393.74	*3676.49*	399.95	*3683.94*	389.75	*3686.95*
11/21/2007	393.70	*3676.53*	399.68	*3684.21*	389.86	*3686.84*

The above values were used to construct a hydrograph, Figure 14, to evaluate potential trends in the water-level data. The hydrograph indicates that MW-2 and MW-3 typically have comparable water-levels. The lowest groundwater elevation consistently occurred in MW-1. The initial water-levels were slightly depressed in each well; however, the elevations were stable with no major trends or fluctuations, except for the two anomalous measurements in MW-2. The anomalously high groundwater elevations recorded for MW-2 in September and December 2004 are believed to reflect an error in measurement due to the absence of a similar response in other on site monitor wells and the relatively consistent water-levels measured since that time.

Groundwater contour maps constructed from the three on site wells depict a uniformly sloping water table surface to the east-southeast as illustrated by Figure 1C through 14C in Appendix C. Review of available information revealed that four (4) additional groundwater monitoring wells exist within one-half mile west of the landfill: EPWU-1, EPWU-2, EPWU-3, and EPWU-4A. The four (4) wells were installed by the El Paso Water Utilities (EPWU) – Public Service Board to monitor a sludge disposal site located immediately west of McCombs Road and north of Stan Roberts Road. Their locations are illustrated on Figures 15, 16 and 17. Completion records and well logs are provided in Appendix A. Geophysical logs for wells EPWU-1, EPWU-2, EPWU-3 were also obtained and are included in Appendix A. Water-levels were measured in the four (4) EPWU wells on July 25, November 9, and November 21, 2007 in an effort to better define the groundwater flow direction in the vicinity of the landfill. Groundwater contour maps constructed using the July and November 2007 water-levels are provided as Figures 15, 16, and 17, respectively. These maps reveal an east to west trending low in the water table surface. According to Figures 15, 16, and 17, groundwater in the northern portion of the landfill flows southeasterly and flow in the southern portion of the site is to the northeast. Groundwater flow directions have been slightly modified following collection of additional water level measurements from August 2011 through July 2012 (see Section 4.8.1). Based on Figures 15, 16, and 17, each of the three (3) existing groundwater monitoring wells was determined to be positioned hydraulically upgradient of the landfill. However, groundwater flow data from August 2011 through July 2012 indicates existing wells MW-1 and MW-2 are downgradient of the landfill and MW-3 is upgradient of the landfill (see Section 4.8.1).

4.7.3 Groundwater Flow Gradient and Rate

Hydraulic gradients were estimated for the saturated zone for various points at the site from the water-level measurements recorded on November 9, 2007. The gradient for a particular part of the site is determined by calculating the difference between the groundwater contours (head difference) and dividing by the horizontal distance between the contours. The values are in ft/ft; multiply by 5,280 for the gradient in feet per mile. Minimum and maximum rates of groundwater movement were estimated using the groundwater velocity equation (Driscoll, 1986):

$v = 2{,}830Ki/ne$

Where:

v = groundwater velocity (ft/day);
K = hydraulic conductivity (cm/sec);
i = hydraulic gradient (ft/ft);
ne = effective porosity (percent); and
2,830 converts cm/sec to ft/day.

The hydraulic conductivity obtained from Anderson (1983) is estimated to be 1.0 x 10^{-2} cm/sec. Minimum and maximum hydraulic gradients were estimated for the saturated zone from Figure 16. Estimated hydraulic gradients range from a minimum of 0.0042 ft/ft in the south-central portion of the site, to a maximum of 0.0106 ft/ft in the southern portion of the site between MW-1 and MW-2. The average effective porosity is estimated to be 30 percent, based on values provided by Freeze and Cherry (1979).

$$v_{min} = \frac{2{,}830 \times 1.00\text{E-}02 \times 0.0042}{0.30}$$

$$v_{min} = 0.396 \text{ ft/day (easterly)}$$

and

$$v_{max} = \frac{2{,}830 \times 1.00\text{E-}02 \times 0.0106}{0.30}$$

$$v_{max} = 1.00 \text{ ft/day (northeasterly)}$$

4.7.4 Groundwater Quality

Groundwater monitoring results from nine groundwater sampling events conducted from May 2004 through May 2007 have been reviewed to determine if any potential groundwater impacts exist. The data indicate that of the 15 heavy metals listed in 30 TAC §330.419 only arsenic, barium and vanadium have been detected and all results for volatile organic compounds are non-detect. Some spatial variation does exist in the available data. Arsenic has been detected in MW-1 and MW-2 at concentrations below the primary drinking water standard of 10 µg/L and barium concentrations in MW-3 are elevated above those in MW-1 and MW-2. Neither arsenic or barium concentrations exhibit an increasing trend. Vanadium concentrations have been increasing in MW-2 and MW-3 since April 2005. Additionally, inorganic indicator constituents magnesium, calcium, potassium, chloride, sodium, and total dissolved solids occur at greater concentrations in MW-3 than MW-1 and MW-2. The occurrence of elevated heavy metals and inorganic indicator constituent in an upgradient well suggests that they are a natural phenomenon unrelated to the landfill. A summary of the existing groundwater analytical data for MW-1,

MW-2 and MW-3 is provided in Appendix D.

4.8 Piezometers PZ-4 and PZ-5

Piezometers PZ-4 and PZ-5 were installed at the McCombs Landfill in May – June, 2011 to aid in the determination of groundwater flow and to determine the extent of the point of compliance (POC). The installation report for PZ-4 and PZ-5 was submitted to the TCEQ on August 12, 2011 (PSC, 2011). Boring logs and well completion diagrams for PZ-4 and PZ-5 are provided in Appendix E. Subsurface sediments encountered during the drilling of PZ-4 and PZ-5 was primarily composed of sand with some interbedded clay lenses and gravels.

A geologic cross section trending west to east through PZ-4 and PZ-5 is included as Figure 18. Geophysical results for El Paso Water Utilities well EPWU-2 and McCombs Landfill wells MW-1 and MW-2 are also illustrated on Figure 18. Geophysical logging did not occur in PZ-4 or PZ-5. Given the interbedded nature of the sands and clays there is no discernable correlation of the stratigraphic units; however, similar variation exists in the lithologic logs and geophysical logs. The measured groundwater surface elevation on July 3, 2012 is also depicted on the geologic cross section. The groundwater surface elevation is generally level with a slight decreasing trend from EPWU-2 through MW-1. A noticeable decrease in groundwater surface elevation occurs between MW-1 and PZ-4. This observable decrease is likely due to drawdown induced by the extraction well (i.e. CEMEX well) located south of the facility and north of Stan Roberts Road.

4.8.1 August 2011 Through July 2012 Water Levels

Monthly water-levels were measured in El Paso Water Utilities wells EPWU-1, EPWU-2, EPU-3, and EPWU-4A; McCombs Landfill wells MW-1, MW-2, MW-3; and piezometers PZ-4 and PZ-5 from August 2011 through July 2012 by the City of El Paso. The recorded groundwater measurements are provided in Table 2. The values in Table 2 were used to construct a hydrograph, Figure 19, to evaluate potential trends in the water-level data. Groundwater elevations in all wells and each piezometer were generally stable from month to month aside from noticeable decreases in PZ-4 over the first two (2) months of measurements. The observable drawdown in PZ-4 was believed to be induced by the extraction well (i.e. CEMEX well) located south of the facility and north of Stan Roberts Road.

Groundwater contour maps from August 2011 through July 2012 are provided in Appendix F (Figures F1 through F12). These maps reveal a predominant easterly to southeasterly flow direction. A northwesterly component of groundwater flow is apparent in the southwest corner of the landfill; however, the flow changes to the east and southeast are believed to be due to drawdown induced by the extraction well (i.e. CEMEX well) located south of the facility and north of Stan Roberts Road. Based on the groundwater contour maps in Appendix F, MW-1 and

MW-2 are downgradient of the landfill and MW-3 is upgradient of the landfill.

5 CONCLUSIONS

Findings of the hydrogeologic evaluations of the McCombs Landfill are summarized below:

- According to information provided by a soil investigation report prepared by DRA, the soil underlying the site predominantly consists of sand with varying silt and gravel contents, and occasional layers of sandy clay. These soils typically are associated with the Pleistocene age Camp Rice Formation.

- Groundwater underlying the site occurs in the Hueco Bolson and Rio Grande Alluvial aquifers. Based on published information, the depth to groundwater at the landfill varies between 370 and 390 feet.

- Regional groundwater flow direction is generally toward the south-southeast.

- Climate in the El Paso region is characterized by an abundance of sunshine, low annual rainfall and high rates of evaporation.

- Climatic conditions indicate a low potential for leachate generation and migration to groundwater at the McCombs Landfill.

- The boring logs for MW-1, MW-2, and MW-3 indicate the subsurface sediments are primarily composed of sand with some interbedded clay lenses and gravels. Most sands above a depth of 350 feet are described as being coarse grained and poorly sorted. Medium grained and fine grained sands appear to become more prevalent below the 350 foot depth.

- Groundwater elevations recorded for the landfill since 2003 are stable and do not indicate any major trends or fluctuations.

- The estimated groundwater velocity for the uppermost water-bearing zone is about 1.0 feet per day.

- Spatial variability is apparent in the groundwater data with arsenic, barium, vanadium, magnesium, calcium, potassium, chloride, sodium, and total dissolved solids occurring at greater concentration in MW-3 than in MW-1 or MW-2.

- Groundwater flow at the McCombs Landfill is predominantly to the east/southeast. A northwesterly component of groundwater flow is apparent in the southwest corner of the landfill; however, the flow changes to the east and southeast likely due to the drawdown induced by the extraction well (i.e. CEMEX well) located south of the facility and north of Stan Roberts Road. MW-1 and MW-2 are downgradient of the landfill and MW-3 is upgradient of the landfill.

6 REVISED GROUNDWATER MONITORING SYSTEM

The TCEQ implemented new 30 TAC 330 Subchapter J rules governing groundwater monitoring and corrective action in 2006 (effective March 26, 2006). Per 30 TAC §330.401(b) *owners and operators of landfill units shall comply with the 2006 Revisions to this subchapter* [Subchapter J] *by applying for a permit modification with public notice in accordance with §305.70(l) of this title (relating to Municipal Solid Waste Permit and Registration Modifications) to revise any inconsistent provisions within two years from the effective date of the 2006 Revisions.*

6.1 Proposed Groundwater Monitoring System

The McCombs Landfill will comply with 30 TAC §330.403(a)(2) by modifying the ground water monitoring system appropriately. The McCombs Landfill will utilize the ground water monitoring system to monitor the uppermost groundwater in accordance with 30 TAC §§330.403-407 to protect human health and the environment.

The proposed groundwater monitoring system was based on the potentiometric surfaces illustrated on the groundwater contour maps provided in Appendix F. As previously discussed, the maps were constructed using water-level data collected from August 2011 to July 2012. The proposed groundwater monitoring system will be comprised of nine (9) monitoring wells: MW-1A, MW-2A, MW-3, MW-4, MW-5, MW-6, MW-7, MW-8, and MW-9. This will be done by plugging and abandoning existing wells MW-1 and MW-2, retaining existing well MW-3, converting existing piezometers PZ-4 and PZ-5 to MW-4 and MW-5, and installing new wells MW-1A, MW-2A, MW-6, MW-7, MW-8, and MW-9. It is proposed that monitoring wells MW-1A, MW-2A, and MW-6 through MW-9 be installed within 180 days of the approval date of this permit modification. Monitoring wells MW-1 and MW-2 will be plugged and abandoned, but will remain a part of the POC until background has been established in wells MW-1A and MW-2A, respectively. Five (5) additional monitoring wells (MW-10, MW-11, MW-12, MW-13, and MW-14) may also be added to the facility groundwater monitoring system in the event the landfill constructs cells in Sectors B, C, D, and E. Well MW-10 would be installed prior to acceptance of waste in Sector B. Wells MW-11 and MW-12 would be installed prior to acceptance of waste in Sector C. Wells MW-13 and MW-14 would be installed prior to waste acceptance in Sector D. If the sequence of landfill sector development changes, the phasing of well installations for MW-10, MW-11, MW-12, MW-13, and MW-14 will be adjusted accordingly as needed to ensure that POC wells will be in place before waste is accepted in a sector. Existing and proposed monitoring wells, the POC, and landfill Sectors are depicted on Figure 20.

Proposed wells MW-1A, MW-2A, MW-4, MW-5, MW-6, MW-7, MW-8, and MW-9 will be

located at the POC (*i.e.,* the vertical surface no more than 500 feet from the hydraulically downgradient limit of the waste management unit boundary, extending down through the uppermost ground water underlying the regulated units, and located on land owned or operated by the McCombs Landfill). Existing well MW-3 will be a background (i.e., upgradient well). Wells MW-10, MW-11, MW-12, MW-13, and MW-14 will also be located at the POC in the event their installation is required. If physical obstacles preclude installation of the groundwater monitoring wells at proposed locations in the existing sectors, the wells will be installed at the closest practical distance hydraulically downgradient from the relevant point of compliance that will ensure detection of groundwater contamination. The design of the monitoring system was based on site-specific technical information. Certification of the system is provided as Appendix G.

The proposed groundwater monitoring wells, with corresponding piezometer numbers (where applicable), and hydraulic gradient positions are listed in the following table.

Proposed Groundwater Monitoring System

Monitoring Well ID	Status	Gradient Position	Latitude and Longitude*	Total Well Depth (ft)**	Top of PVC Casing Elevation (ft MSL)**	Screen Interval Depths (ft)**	Screen Interval Elevations (ft. MSL)**
MW-1	Existing (To be plugged and abandoned)	POC	N 31°59'00.64" W 106°24'14.07"	473	4,070.23	461 to 473	3,606.35 to 3,594.35
MW-1A	New	POC	N 31°59'17.96" W 106°24'14.51"	416	4,070	396 to 416	3,671 to 3,651
MW-2	Existing (To be plugged and abandoned)	POC	N 31°59'00.54" W 106°24'25.57"	498	4,083.89	478 to 498	3,603.06 to 3,583.06
MW-2A	New	POC	N 31°59'17.85" W 106°24'26.02"	424	4,084	404 to 424	3,677 to 3,657
MW-3	Existing	Background	N 31°59'43.41" W 106°24'13.34"	495	4,076.70	475 to 495	3,598.68 to 3,578.68
PZ-4	Existing (Convert to MW-4)	POC	N 31°59'18.82" W 106°24'07.71"	465	4,049.64	413 to 463	3,634.28 to 3,584.28
PZ-5	Existing (Convert to MW-5)	POC	N 31°59'29.27" W 106°23'53.85"	440	4,061.05	418 to 438	3,640.44 to 3,620.44
MW-6	New	POC	N 31°59'17.90" W 106°24'21.29"	408	4,067	388 to 408	3,676 to 3,656

Proposed Groundwater Monitoring System (continued)

Monitoring Well ID	Status	Gradient Position	Latitude and Longitude*	Total Well Depth (ft)**	Top of PVC Casing Elevation (ft MSL)**	Screen Interval Depths (ft)**	Screen Interval Elevations (ft. MSL)**
MW-7	New	POC	N 31°59'18.57" W 106°24'0.75"	462	4,065	412 to 462	3,650 to 3,600
MW-8	New	POC	N 31°59'18.93" W 106°23'53.86"	443	4,071	423 to 443	3,645 to 3,625
MW-9	New	POC	N 31°59'23.93" W 106°23'53.78"	443	4,071	423 to 443	3,645 to 3,625
MW-10	Potential (Install if landfill expands to Sector B)***	POC	N 31°59'35.15" W 106°23'53.83"	446	4,080	426 to 446	3,651 to 3,631
MW-11	Potential (Install if landfill expands to Sector C)***	POC	N 31°59'41.04" W 106°23'54.00"	441	4,079	421 to 441	3,655 to 3,635
MW-12	Potential (Install if landfill expands to Sector C)***	POC	N 31°59'46.93" W 106°23'54.00"	433	4,076	413 to 433	3,660 to 3,640
MW-13	Potential (Install if landfill expands to Sector D)***	POC	N 31°59'52.81" W 106°23'54.12"	416	4,064	396 to 416	3,665 to 3,645
MW-14	Potential (Install if landfill expands to Sector D)***	POC	N 31°59'58.70" W 106°23'54.16"	406	4,059	386 to 406	3,670 to 3,650

* - Locations of new and potential wells may be adjusted based on site conditions at time of drilling. 600 foot spacing will be maintained.
** - Depths and elevations for new and potential wells are estimated.
*** - If the sequence of landfill sector development changes, the phasing of well installations will be adjusted accordingly as needed to ensure that POC wells will be in place before waste is accepted in a sector.

The new monitoring wells will be installed by a Texas licensed monitoring well driller in accordance with TCEQ monitoring well specifications. They will be completed in a manner not to introduce contaminants. The monitoring well installation and development be supervised by a geologist or engineer who is familiar with the area geology. Anticipated construction details for the new wells are provided in the table on the following page:

Well Construction Specifications

Well Depths	All wells approximately 25 feet into saturated zone, except MW-7. MW-7 installed approximately 55 feet into saturated zone to account for CEMEX well drawdown
Well Materials	4" diameter sched. 80 PVC, flush threaded with screw joints, and o-rings.
Screen	MW-7 - Approximately 50 ft section, machine slotted with 0.010" slots. All other wells - Approximately 20 ft section, machine slotted with 0.010" slots.
Filter Pack	Inert 10/20 silica sand extending approx. 2 ft above top of screen.
Annular Seal	30 ft thick, composed of hydrated sodium bentonite pellets or granules.
Casing Seal	Bentonite grout or cement-bentonite grout placed from the annular seal to within approximately 2 ft. of the surface.
Concrete Pad	A 4' x 4' x 6" reinforced concrete pad extending to grout below surface.
Protective Casing and Bollards	Four-inch steel locking protective casing and two bollards placed outside of concrete pad.

Note: Well depths may vary based on field conditions and the actual elevation of the groundwater producing interval encountered during drilling.

Project Description: 2011 McCombs Landfill Piezometer Installations

CAREL CORPORATION

Location: McCombs Landfill
Top of PVC El.: 4049.64 feet MSL
Surface El.: 4047.28 feet MSL
Completion Depth: 466 feet
Date Boring Started: 5/26/2011
Date Boring Completed: 6/2/2011

Latitude: 31.988560
Longitude: 106.402142

Depth, feet	Samples	Symbol/USCS	MATERIAL DESCRIPTION	Piezometer Construction Details	Piezometer Description
0–5			SAND, tan, well graded, subangular to angular, fine to cobble grained, dry, loose, some gravel, carbonate cement		Concrete from surface to 2' bgs
5–10					
10–15			SAND, light grayish red brown, well graded, round to subangular, fine to pebble grained, dry, loose, some gravel, some volcanic rock fragments, quartz rich with mafic gravel and volcanic rocks, multicolored grains		
15–20					
20–25			SAND, light reddish brown to brown, poorly graded, rounded, fine grained, dry, loose, quartz rich with mafic minerals, multicolored grains		
25–30					
30–35					
35–40					
40–45			SANDY GRAVEL, light brown, well graded, round to angular, fine to gravel grained, dry, loose, quartz rich with mafic minerals, multicolored grains		
45–50					
50–55			SAND, dark brown, well graded, fine to pebble grained, dry, loose, and gravel, iron oxide staining, quartz rich with multicolored grains		
55–60					
60–65			SAND, light grayish brown, well graded, round to subangular, fine to pebble grained, dry, loose, and gravel, with volcanic rock fragments, with limestone, quartz rich with multicolored grains		
65–70					
70–75			SAND, light brown, well graded, dry, loose, and gravel, quartz rich with mafic minerals, multicolored grains		
75–80					
80			CLAY, reddish brown, dry		
80–85			SAND, light brown, well graded, subrounded, fine to medium grained, dry, loose, iron oxide staining, quartz rich with mafic minerals, multicolored grains		
85–90					
90–95			SAND, light brown, well graded, fine to pebble grained, dry, loose, and gravel, quartz rich with mafic minerals, multicolored grains

Monitor Well Data Sheet

Permittee or Site Name: McCombs Landfill
County: El Paso County
Date of Monitor Well Installation: June 1, 2011
Latitude: 31°59'18.81720" Longitude: 106°23'53.84750"
Monitor Well Groundwater Gradient Position:
Upgradient: _____ Downgradient: _____

MSW Permit No.: 729A
Monitor Well I.D. No.: PZ-4
Date of Monitor Well Development: June 8, 2011
Monitor Well Driller
Name: William B. Bludworth
License No. 4885

NOTES:

- Report all depths from Surface Elevation and all Elevations relative to Mean Sea Level (MSL), to nearest hundredth of a foot.
- Diameter of boring should be at least 4 inches larger than diameter of well casing.
- Use flush screw joint casing only, 2-inch diameter or larger, with o-rings or PTFE tape in joints (4-inch diameter recommend).
- Well development should continue until water is clear, and pH and conductivity are stable.

Geologist, Hydrologist, or Engineer Supervising Well Installation: Michael J. Hull, PG
Static Water Level Elevation (with respect to MSL) after Well Development: 3,650.81' MSL
Name of Geologic Formation(s) in which Well is completed: Hueco Bolson

Type of Locking Device: Pad Lock Type of Casing Protection: 6" x 6" x 5' Steel
Concrete Surface Pad (with steel reinforcement) Dimensions: 4' x 4' x 6"

Monitor Well Data Sheet

Permittee or Site Name: McCombs Landfill
County: El Paso County
Date of Monitor Well Installation: May 25, 2011
Latitude: 31°59'29.26715" Longitude: 106°23'53.84750"
Monitor Well Groundwater Gradient Position:
Upgradient: _____ Downgradient: _____

MSW Permit No.: 729A
Monitor Well I.D. No.: PZ-5
Date of Monitor Well Development: June 7, 2011
Monitor Well Driller
Name: William B. Bludworth
License No. 4885

NOTES:

- Report all depths from Surface Elevation and all Elevations relative to Mean Sea Level (MSL), to nearest hundredth of a foot.
- Diameter of boring should be at least 4 inches larger than diameter of well casing.
- Use flush screw joint casing only, 2-inch diameter or larger, with o-rings or PTFE tape in joints (4-inch diameter recommend).
- Well development should continue until water is clear, and pH and conductivity are stable.

Geologist, Hydrologist, or Engineer Supervising Well Installation: Michael J. Hull, PG
Static Water Level Elevation (with respect to MSL) after Well Development: 3,653.97' MSL
Name of Geologic Formation(s) in which Well is completed: Hueco Bolson

Type of Locking Device: Pad Lock Type of Casing Protection: 6" x 6" x 5' Steel
Concrete Surface Pad (with steel reinforcement) Dimensions: 4' x 4' x 6"

APPENDIX G

GROUNDWATER MONITORING SYSTEM DESIGN CERTIFICATION

Appendix 3K – Attachment 2
2-Mile Water Wells

Memorandum

SAIC

To: TCEQ

From: Randall J. Sippel, P.G., SAIC

Subject: Water Well Search

Date: July 9, 2012

SAIC Energy, Environment & Infrastructure, LLC has conducted a water well search for the McCombs Landfill located in El Paso County, El Paso, Texas in accordance with 30 TAC §330.63(e)(3)(J). The water well search was conducted utilizing the online Texas Water Development Board (TWDB) Water Information Integration and Dissemination (WIID) database. Site coordinate boundaries were entered into the database (buffer numbers 1 through 4) and a 2-mile boundary was placed on the buffer numbers (see attached figure). All scanned well logs located within the approximate 2-mile radius were downloaded from the TWDB website and are included as an attachment to this memo. The scanned quality of the documents is as they were located on the TWDB website and are considered the best version available. The wells located within the search radius include the following:

Table 1

Water Well Search

4905201	4905202	4905203	4905204	4905205
4905208	4905212	4905213	4905214	4905215
4905216	4905217	4905218	4905219	4905220
4905221	4905222	4905223	4905224	4905225
4905226	4905227	4905301	4905302	4905303
4905304	4905305	4905306	4905307	4905308
4905309	4905310	4905311	4905312	4905313
4905314	4905315	4905316	4905317	4905318
4905319	4905320	4905321	4905322	4905323
4905324	4905325	4906102	4906104	4906105

This information was also provided to TCEQ in a letter from Parkhill, Smith & Cooper (PSC) dated July 6, 2009, responding to a TCEQ comment letter of May 4, 2009 regarding the permit modification of the groundwater monitoring system for the City of El Paso McCombs Municipal

SAIC Energy, Environment & Infrastructure, LLC

Landfill, MSW Permit No. 729A. The Water Well Search map, Figure 4 and Water Well Inventory, Table 1, of that letter are also provided with the TWBD well logs. In addition to the wells listed above, well sealing and redrilling records for the Cemex replacement well (2007) is located in the attachment.

TEXAS WATER DEVELOPMENT BOARD

WELL SCHEDULE

Aquifer Hueco Bolson Field No. E-3 R-78 State Well No. 49 05 201

Owner's Well No. _____ County El Paso

1. Location: NE 1/4, NW 1/4 Sec. 2, Block 81 Survey _____
NEC
31 59 52 N 106 26 10 1

2. Owner: City of El Paso Address: _____

3. Tenant: El Paso Electric Co Address: _____

Driller: City Address: _____

3. Elevation of LSD is 4060 ft. above msl, determined by Topo

4. Drilled: 12 1958; Dug, Cable Tool, Rotary, _____

5. Depth: Rept. 631 ft. Meas. _____ ft.

6. Completion: Open Hole, Straight Wall, Underreamed, Gravel Packed _____

7. Pump: Mfgr. Layne-Bowler Type turbine

No. Stages 11, Bowls Diam. _____ in., Setting 450 ft.

Column Diam. _____ in., Length Tailpipe _____ ft.

8. Motor: Fuel Elec Make & Model _____ HP. 200

9. Yield: Flow _____ gpm, Pump 1480 gpm, Meas., Rept., Est. 2/24/59

10. Performance Test: Date _____ Length of Test 24 Made by _____

Static Level _____ ft. Pumping Level _____ ft. Drawdown 48.8 ft.

Production 1480 gpm Specific Capacity SC 30.3 gpm/ft.

CASING & BLANK PIPE
Cemented From _____ ft. to _____ ft.

Diam. (in.)	Type	Setting, ft. from	to
24	Stl		
18	"		
12	"	498	bottom

11. Water Level: 351.4 ft. rept. meas. 1/6 1957 above below top of meas'g pipe which is 2.5 ft. above below surface.

_____ ft. rept. meas. _____ 19__ above below which is _____ ft. above below surface.

_____ ft. rept. meas. _____ 19__ above below which is _____ ft. above below surface.

_____ ft. rept. meas. _____ 19__ above below which is _____ ft. above below surface.

12. Use: Dom., Stock, Public Supply, Ind., Irr., Waterflooding, Observation, Not Used, _____

13. Quality (Remarks on taste, odor, color, etc.) _____

Temp. ___ °F, Date sampled for analysis 2/25/59 Laboratory _____

Temp. ___ °F, Date sampled for analysis _____ Laboratory _____

Temp. ___ °F, Date sampled for analysis _____ Laboratory _____

14. Other data available as circled: Driller's Log, Radioactivity Log, Electric Log,

Formation Samples, Pumping Test, _____

WELL SCHEDULE

Aquifer Hueco Bolson Field No. R-72 State Well No. 49-05-301

Owner's Well No. 42 County El Paso

1. Location: ___ 1/4, ___ 1/4 Sec. ___, Block ___ Survey ___

2. Owner: City of El Paso Address: ___

Tenant: ___ Address: ___

Driller: City Address: ___

3. Elevation of 4017.5 is ___ ft. above msl, determined by ___

4. Drilled: April 1958; Dug, Cable Tool, Rotary

5. Depth: Rept. 670.87 ft. Meas. ___ ft.

6. Completion: Open Hole, Straight Wall, Underreamed, Gravel Packed

7. Pump: Mfgr. U.S. Pumps Type turbine

No. Stages 12, Bowls Diam. 14 in., Setting 420 ft.

Column Diam. ___ in., Length Tailpipe ___ ft.

8. Motor: Fuel Elec Make & Model Allis-Chalmers HP. 250

9. Yield: Flow ___ gpm, Pump 1250 gpm, Meas., Rept., Est.

10. Performance Test: Date 6/16/60 Length of Test 8 hrs Made by ___

Static Level ___ ft. Pumping Level ___ ft. Drawdown 365 ft.

Production 1600 gpm Specific Capacity ___ gpm/ft.

CASING & BLANK PIPE
Cemented From 0 ft. to 314 ft.

Diam. (in.)	Type	Setting, ft. from	to
24	Steel	0	314
18	Steel	0	319.66
Swage		504.83	507.33

11. Water Level: 319.4 ft. rept. meas. 6/13 1960 above below Meas pipe which is 3.0 ft. above below surface.

340.27 ft. rept. meas. 1/7 1975 above below USD which is ___ ft. above below surface.

___ ft. rept. meas. ___ 19__ above below ___ which is ___ ft. above below surface.

___ ft. rept. meas. ___ 19__ above below ___ which is ___ ft. above below surface.

12. Use: Dom., Stock, Public Supply, Ind., Irr., Waterflooding, Observation, Not Used, Test well

13. Quality: (Remarks on taste, odor, color, etc.) ___

Temp. ___ °F, Date sampled for analysis ___ Laboratory ___

Temp. ___ °F, Date sampled for analysis ___ Laboratory ___

Temp. ___ °F, Date sampled for analysis ___ Laboratory ___

SAMPLE OF: Water RECEIVED: April 8, 1955.
MARKED: Price's Dairy, 20 miles north of El Paso and 2 miles west of Highway 54, El Paso, Texas. Well No. 1, Sample No. 2, screen 602-622, static head 338, cone packer at 598, taken 4-6-55 after 8 hours pumping with air at 5 G.P.M. T. P. Bryant.

CERTIFICATE OF ANALYSIS
Parts per Million:

Calcium Bicarbonate	210
Magnesium Bicarbonate	72
Sodium Bicarbonate	92
Sodium Carbonate	42
Sodium Sulfate	186
Sodium Chloride	416
Silica	17
Iron Oxide	0.3
Aluminium Oxide	1.7
Volatile & Organic Matter	30.
Total Solids	1067.

Total Hardness as Calcium Carbonate	180
Phenolphthalein Alkalinity	20
Methyl Orange Alkalinity	274
Free Carbon Dioxide	0
pH	8.55

IONS:

Calcium	52	Bicarbonate	285
Magnesium	12	Carbonate	24
Sodium (Diff.)	267	Sulfate	126
Iron (Fe) (Filt.)	0.2	Chloride	252
Iron (Fe) (Unfilt)	1.8		

Appearance: Quite turbid (light yellowish). Analysis on filtered water.

SAMPLES OF: Two Waters RECEIVED: April 15, 1955.
MARKED: Price's Dairy, 20 miles North of El Paso, Texas and 2 miles West of Highway 54, Well No. 1.

CERTIFICATE OF ANALYSIS
Parts per Million:

Sample No.	#3 4-11-55	#4 4-13-55
Screen	726-746	836-857
Static head	342	294
Cone Packer set at	724	834
Pumped with air	8 hrs. at 5 CFM	5 hrs. at 12 PSI
Taken by	L. P. Bryant	Albert Caren
Calcium Bicarbonate	124	154
Calcium Carbonate	10	10
Calcium Sulfate	105	121
Calcium Chloride	50	42
Magnesium Chloride	63	78
Sodium Chloride	826	1338
Silica	18	[illegible]
Iron Oxide	0.1	0.1
Aluminium Oxide	3.9	2.9
Volatile & Organic Matter	39.	48.
Total Solids	1239.	1818.
Total Hardness as Calcium Carbonate	276	315
Phenolphthalein Alkalinity	5	5
Methyl Orange Alkalinity	86	105
Free Carbon Dioxide	0	0
pH	7.90	8.10
IONS:		
Calcium	84	93
Magnesium	16	20
Sodium (Diff.)	325	527
Bicarbonate	93	116
Carbonate	6	6
Sulfate	74	85
Chloride	580	896
Iron (Fe)	0.1	0.1

Appearance: Both samples quite turbid. Analyses on filtered water.

Respectfully submitted,

Aquifer Hueco Bolson Field No. R-100 State Well No. 49 05 306

Owner's Well No. 61 County El Paso

1. Location: ___ 1/4, ___ 1/4 Sec. ___, Block ___ Survey ___

2. Owner: City of El Paso Address: ___

Tenant: ___ Address: ___

Driller: City Address: ___

3. Elevation of 4053.5 is ___ ft. above msl, determined by TW2-TOPO

4. Drilled: May 19 65; Dug, Cable Tool, (Rotary)

5. Depth: Rept. 603 ft. Meas. ___ ft.

6. Completion: Open Hole, Straight Wall, (Underreamed), (Gravel Packed)

7. Pump: Mfgr. ___ Type Turbine

No. Stages ___, Bowls Diam. ___ in., Setting ___ ft.

Column Diam. ___ in., Length Tailpipe ___ ft.

8. Motor: Fuel Elec Make & Model ___ HP. ___

9. Yield: Flow ___ gpm, Pump ___ gpm, Mess., Rept., Est.

10. Performance Test: Date 8/4/65 Length of Test 12 hrs Made by ___

Static Level ___ ft. Pumping Level 444 ft. Drawdown 77.45 ft.

Production 1200 gpm Specific Capacity ___ gpm/ft.

11. Water Level: 367.02 ft. (rept.) (meas.) 8/5 1965 (above) below Top of M.P. which is 3.0 ft. (above) below surface.

359.7 ft. rept. meas. 1-20 1970 above (below) LSD which is ___ ft. above below surface.

366.75 ft. rept. meas. 1/6 1975 above (below) LSD which is ___ ft. above below surface.

___ ft. rept. meas. 19___ above below which is ___ ft. above below surface.

12. Use: Dom., Stock, (Public Supply), Ind., Irr., Waterflooding, Observation, Not Used, ___

13. Quality: (Remarks on taste, odor, color, etc.) ___

Temp. ___ °F, Date sampled for analysis ___ Laboratory ___

Temp. ___ °F, Date sampled for analysis ___ Laboratory ___

Temp. ___ °F, Date sampled for analysis ___ Laboratory ___

14. Other data available as circled: Driller's Log, Radioactivity Log, (Electric Log),

Formation Samples, Pumping Test, ___

15. Record by: TWDB-El Paso Date ___ 1972

Source of Data USGS well schedule by M.E. Davis 5/18/65

Diluted Conductance (micromhos/cm3): _____ x _____ = 722

" ☐ " items will be analyzed if checked.

		MG/L	ME/L
Carbonate	00445	0	
Bicarbonate	00440	98	
Sulfate	00945	40	
Chloride	00940	146	
Fluoride	00951	7	
Nitrate	71850	3.50	
pH	00403		
	Total		
[1] Dissolved Solids (residue at 180°C)	70300	416	
Phenolphthalein Alkalinity as $CaCO_3$	00415		
Total Alkalinity as $CaCO_3$	00410		
Total Hardness as $CaCO_3$	00900	94	
[2] Nitrogen Cycle			
Ammonia - N	00610		
Nitrite - N	00615		
Nitrate - N	00620		
Organic Nitrogen	00605		

[1] The bicarbonate reported in this analysis can be converted by computation (multiplying by 0.4917) to an equivalent amount of carbonate, and the carbonate figure used in the computation of dissolved solids.
[2] Nitrogen cycle requires separate sample.
[3] Total Iron and Manganese require separate sample.

2)LOCATION OF WELL:

The sketch showing the well location must be as accurate as possible, showing [illegible], in such a manner that the well may be plotted on a General Highway Map of the county in which the well is located.

Reference points from which distances are measured and directions given should be some permanent landmark such as intersections, center of towns, river and creek bridges, railroad crossings, etc. The distance and direction from the nearest town should always be indicated.

When giving a legal description include a sketch showing location of the well within the described [illegible].

Information furnished in Section 2) of the TWDBE-GW-53 is very important. Unless the well can be [illegible] the value of the other data contained in the Report is greatly reduced.

220 - 260 Sandy & clay
260 - 300 clay gray
300 - 325 clay - sandy
325 - 355 clay - gray
355 - 360 water sand
360 400 sand
400 450 sand
450 500 sandy clay
500 550 sand
550 600 sand

Type: Old New Steel Plastic Other
Cemented from ______ ft. to ______ ft.

Diameter (inches)	Setting From (ft.)	Setting To (ft.)	Gage

10) SCREEN:
Type ______
Perforated Slotted

Diameter (inches)	Setting From (ft.)	Setting To (ft.)	Slot Size

7) COMPLETION (Check):
Straight wall | Gravel packed | Other
Under reamed | Open Hole

8) WATER LEVEL:
Static level ______ ft. below land surface Date ______
Artesian pressure ______ lbs. per square inch Date ______
Depth to pump bowls, cylinder, jet, etc., ______ ft. below land surface.

11) WELL TESTS:
Was a pump test made? Yes No If yes, by whom?
Yield: ______ gpm with ______ ft. drawdown after ______ hrs.
Bailer test ______ gpm with ______ ft. drawdown after ______ hrs.
Artesian flow ______ gpm
Temperature of water ______

12) WATER QUALITY:
Was a chemical analysis made? Yes No
Did any strata contain undesirable water? Yes No
Type of water? ______ depth of strata ______

I hereby certify that this well was drilled by me (or under my supervision) and that each and all of the statements herein are true to the best of my knowledge and belief.

Comments:
[1] Matrix Spike Recovery is outside acceptable limits. All other associated QC within acceptable limits.
[2] Matrix Spike Duplicate is outside acceptable limits. All other associated QC within acceptable limits.

Laboratory analyses were performed on samples utilizing procedures published in Standard Methods for the Examination of Water and Wastewater, 18th Edition 1992, or in EPA Methods for the Determination of Metals in Environmental Samples [EPA-600/4-91-010], June 1991 and the latest promulgated updates. ND, where noted, indicates Not Detected, with the detection limit listed.

El Paso, Texas 79907

RE: Replacement of Groundwater Well
McCombs Quarry
6101 Stan Roberts
El Paso, Texas 79934

Dear Ms. Smyth:

Cemex would like to inform the City of El Paso and the El Paso Water Utilities of a new location of a ground water well in order to replace the groundwater well located within the McCombs Landfill property boundary which collapsed and is no longer operable (see attached aerial photo).

According to the 2003 lease agreement between the El Paso Water Utilities, the City of El Paso, and Cemex (formerly Jobe), in the "Lease of Wells" section (Attached) it states the installation of a replacement well is the responsibility of the LESSEE. Cemex would like to install the replacement well in the 12.1754 acre parcel where the material center is currently located. The replacement well will be identical to the previous well located on the western boundary of the McCombs Landfill. The replacement well will be drilled 560 feet below ground level. The new four inch pump to be installed will produce the same capacity as the one being replaced (175 to 200 gallons per minute). The well will be installed approximately 212 feet north of Stan Roberts Sr. Avenue and approximately 71 feet east of the McCombs Landfill fence line. Cemex is scheduling the work to start during the week of March 26, 2007.

If you have any questions or need additional information, please do not hesitate to call me at (915) 564-1653.

for Materials removed during the month of March, shall be due and payable 15 days after the needed indexes are published.

4. **Lease of Wells**

In addition to Parcels I, II and III, described above, LESSOR also leases by this agreement to LESSEE a tract of land shown on Exhibit "D" attached hereto and identified as containing the LESSEE wells, which tract contains approximately 1.84 acres more or less and is the location site of two wells owned by LESSOR, which LESSOR hereby leases to LESSEE (hereinafter the "Well Site") described in Exhibit "D-2). LESSEE acknowledges the water produced from the wells shall only be used by it at its quarry operations upon other property leased. The discharge lines from such wells shall be metered and LESSOR shall bill LESSEE monthly on the amount of water used by LESSEE. For water use from the date of commencement of this lease through the end of December of 2003, LESSEE shall pay to LESSOR the sum of $0.48 per CCF. For the years 2004 through 2010, the price shall be calculated in accordance with the schedule attached hereto as Exhibit "E". The prices during the term of this lease will be pursuant to the schedule attached. In addition, LESSEE shall own the well pumping equipment and the transmission lines necessary for transporting such water from the wells to LESSEE's operations and shall have full responsibility for the maintenance and repairs of all well pumping equipment, transmission lines, and other appurtenances relating to such water wells. LESSEE shall also bear the cost for the electric bill or other energy cost associated for the pumping of such wells. If either or both of such wells shall fail, cave in or otherwise cease to be useable for the purposes anticipated herein, then LESSEE at its own expense, shall have the right to drill a new replacement well on either the 12.1754 acre parcel described in Exhibit "C" attached hereto, or on a site on Parcel II or its choosing, for purposes of providing the water required hereunder. If LESSEE should drill a new well, it shall bear all cost and expense of the drilling of such well and equipment the same, but shall not relieved of its obligation to pay LESSOR the fee per CCF of water pumped, as described hereinabove.

LESSOR and EPSW shall grant to LESSEE an new easement for a pipeline from the two wells described above, to provide a means whereby LESSEE can take the water by pipeline from those wells to its operating site. The route of such easement will be shown on Exhibit "D" attached hereto, and will be generally in a southerly direction from the wells, immediately adjacent to the west boundary of LESSOR/EPSW property, proceeding south toward Stan Roberts Avenue, until the landfill operation has been cleared, and then proceeding east, parallel to Stan Roberts Avenue, until it reaches LESSEE's property identified as Parcel III.

Job No. 02-02-15768B | Scale: 1" = 300' | Date: December 3, 2002

Appendix 3K – Attachment 3
Borings

Memorandum

SAIC

To: TCEQ

From: Randall J. Sippel, P.G., SAIC RJS

Subject: Appendix 3K, Attachment 3 – Boring Logs

Date: July 9, 2012

SAIC Energy, Environment & Infrastructure, LLC (SAIC) has included the site boring logs completed by Danny R Anderson, Consultants (DRA) in May 1983 and November 1983 for TCEQ information. The boring information provided is considered adequate and generally conforms to 30 TAC § 330.63(e).

This permit application is related to a vertical expansion of the permitted landfill, therefore, the originally permitted landfill footprint will remain the same. There is no change in the base grades nor is there any lateral expansion of the permitted waste disposal area. Discussion with TCEQ staff prior to starting work on this permit modification and during the subsequent permit application review and comment period indicate that no additional geologic site characterization is necessary since there is not a horizontal expansion of the landfill. As per these discussions with TCEQ staff, an updated geology report is not necessary unless requesting a lateral expansion of the permitted waste disposal area.

SAIC has reviewed the reports related to the regional and site specific geology completed for the previous permit application and subsequent modifications and finds the reports adequate for the existing landfill.

Re: Northeast Sanitary Landfill
El Paso, Texas
File No. 82182

Dear Mr. Harned:

In response to a request from the Texas Department of Health, we include the following addendum to our soils report dated May 3, 1983. Please attach this to all copies of our soil report so it may be considered a part of said report.

Begin Addendum No. 1:

We have completed fifteen additional borings to a depth of sixty feet in the area making the balance of 327 acres from the initially proposed 75 acre site.

Also enclosed, information for the area immediately north of the existing landfill from a subsurface investigation conducted by Dickinson Laboratories, Inc., in June of 1976.

The locations of the borings are as shown on Sheet A1 in the Appendix of this report. The soils encountered are shown on the attached Log of Boring Sheets A1/1 through A1/27.

End Addendum No. 1.

Should you require further information, please call us.

Sincerely,

Danny R. Anderson, P.E.

Re: Northeast El Paso Sanitary Landfill
El Paso, Texas
File No. 82192

Dear Mr. Harned:

We have completed a geotechnical investigation at the above named site. The attached report describes the investigation techniques and the data obtained, together with our engineering recommendations for landfill design and site preparation.

We are pleased to assist you on this phase of your project, and look forward to serving you in the future. If we may be of further assistance, please call us.

Sincerely,

Danny R. Anderson, P.E.

1. INTRODUCTION

We were authorized by the City of El Paso to perform a geotechnical investigation at the site of the proposed Northeast El Paso Sanitary Landfill Expansion. The 327 acre site is located in northeast El Paso in Section 6, Block 80, Township 1. It is situated in the northeast corner of the intersection of McCombs Road and FM2529. The proposed expansion will be to the north, west and east of the existing sanitary landfill operated by the City of El Paso.

The proposed site has been set aside as a mineral resource area, and will continue to be quarried for sand and mineral deposits. The area immediately west of the existing landfill is a pit which remains as a result of this operation.

The purpose of our geotechnical investigation was to determine the types of soils present at the site and their physical properties which relate to permeability, slope stability, and subgrade for roads.

2. INVESTIGATION

2.1 Subsurface soil strata and conditions at the site were determined by visual inspection of materials recovered from eight 8 inch O.D., hollow stem auger borings. The locations of the borings are as shown on Sheet A1 of the Appendix of this report.

Continuous sampling of subsurface soils was provided by the auger as well as split spoon samples which were recovered through the hollow

PT 8

stem. A two inch O.D., split tube sampler was used in obtaining disturbed samples and in determining standard penetration values of all soil strata. Samples were field extracted and classified, identified according to boring number and depth, and placed in moisture-proof containers for transportation to the laboratory for tests and further study. The soils encountered are shown on the Log of Boring Sheets A2 through A9 in the Appendix. Symbols and classifications shown on the logs are based on the Unified Soil Classification System. A key to the classification symbols is shown on Sheet A47.

2.2 All samples of subsurface materials from the borings were examined and classified in the laboratory. Atterberg Limits and grain size determinations were performed on typical samples to establish index properties and aid in proper classification of soil strata. The results of thirty-seven grain size determinations are shown on Sheet A10 through A46. Index properties are shown on the boring logs adjacent to the depth at which the sample was recovered.

3. SITE CONDITIONS AND SUBSOIL PROFILE

3.1 The proposed landfill site is located on the broad lowland surface of the Hueco Bolson. The soils of the site are predominantly alluvial sands and gravels.

3.2 The site is located on a high point sloping north, west, and south. The average rate of drop away from this high point is approximately 1.5%.

T 8

3.3 The site has sparse vegetation with primary growth consisting of desert dropseed grasses and woody plants of creosotebush and mesquite.

3.4 The soils at the site are predominantely poorly graded sands, either gravelly sands (SP group, Unified Soil Classification), or clayey sands (SC group). The SP and SC group materials exhibit low and medium plasticity respectively. A layer of clay is reported at depths of 44 to 49 feet (Boring Number 2), 24 to 28 feet (Boring Number 3), and 30 to 32 feet (Boring Number 7), all in the proposed landfill area. Elsewhere, thin clay lenses are reported below 20 feet.

3.5 The groundwater table was not encountered in any of the test borings. Based on information obtained from several wells that exist in the vicinity of the proposed landfill, we would expect the groundwater table to be encountered at approximately three hundred and fifty feet below existing grade.

4. DISCUSSION AND RECOMMENDATIONS

4.1 We understand that landfill operations wil start on the first 70 acres made available by the sand and gravel operator. Part of this area will include the existing pit, with depths of 50 to 60 feet and approximately 1:1 slopes (1 horizontal to 1 vertical). We recommend these slopes and future ones to be shaped according to the requirements of Section 4.3 of this report.

T 8

The material for cover, for the proposed landfill will be obtained from the overburden of mining operations. If this material has not been stockpiled by the sand and gravel operator, it will be removed directly from its natural location.

We understand that the State Health Department requirements are such that all finish slopes shall be a minimum of 4 to 1 (4 horizontal to 1 vertical). In order to maximize the fill volumes available, temporary cut and/or fill slopes should be as steep as safety will allow.

We understand that the State Health Department requires that a natural and/or artificial lining be present at the base of the landfill cells to prevent leachate migration. Where natural soils deposits exist, the premeability coefficient of the material shall be less than 1×10^{-7} (cm/sec).

4.2 Due to the nature of the materials at the site, laboratory permability tests were not deemed necessary for this project. The materials are predominately clean uniform sands with a coefficient of permeability much higher than that required for a cell liner. By emperical methods, we predict the coefficient of permeability to be 0.01 to 0.04 cm/sec.

4.3 Clean, dry sands are stable regardless of their height, provided the slopes do not exceed their angle of internal friction. Therefore, we recommend that all cut and/or fill slopes required to construct the

T 8

fill cells be 1 1/2 to 1 (1 1/2 horizontal to 1 vertical). This will provide a factor of safety against a sliding failure of 1.0 which we consider adequate for temporary slopes.

All permanent slopes, other than those connected to the landfill and required to be 4 to 1, shall have a minimum slope of 2 horizontal to 1 vertical.

4.4 Fill material for site grading for permanent facilities shall be free of any organic or deleterious substance and shall not contain rocks or lumps over four inches in greatest dimension and, in addition, shall not consist of more than 60 percent by weight of rock larger than No. 4 sieve, and not more than 40 percent passing No. 200 sieve. The fill shall show low shrinkage or swelling when subjected to changes in moisture content and its plasticity index shall not exceed twelve. Grain size analysis, text for liquid limit, for plastic limit, shrinkage limit and computation of the plasticity index shall be performed in accordance with ASTM D422, D423, D424, and D427 respectively.

Prior to placing any backfill, all fill materials should be sampled, tested and approved by the geotechnical engineer. The surface on which the material is to be placed shall be scarified to a depth of six inches, watered to add the amount of moisture required for optimum compaction, then compacted to the required density.

PT 8

The fill material shall be placed in lifts not to exceed six inches in depth and then compacted. The moisture content of the materials shall be uniform and within plus or minus two percent of the optimum value as determined by ASTM D1557.

Compaction of the fill material shall be performed with approved types of power, vibratory, pneumatic or tamping equipment. Each lift of fill shall be compacted to a relative compaction which is not less than 95 percent of maximum density as determined by ASTM D1557. Determination of density in the field shall be in accordance with the requirements of ASTM D1556 or D2922.

Control of the backfilling shall consist of field inspection and testing to determine that each lift of fill has been compacted to the required density. Should any lift or portion of a lift not conform to the density requirements, the lift shall be scarified and recompacted until the required density is obtained.

Fill for the landfill operation shall have a quality and placement requirement as specified on the plans.

4.5 · We recommend that the pavement structure throughout the project area consist of one and one half inches of HMAC, four inches of crushed stone base on twelve inches of compacted subgrade. Where heavy truck traffic is expected, we recommend that we be notified to provide additional recommendations. Subgrade soils shall be excavated to the

required grade and compacted as stated previously in this report. Base course shall meet the requirements for Type "B", Grade 2 material according to Item 248, Flexible Base, Texas Highway Department, 1982 Standard Specifications for Construction of Highways, Streets, and Bridges. All other requirements of this document shall be met except where density is specified, the density shall be not less than 100% as determined by ASTM D1556 and D2922. The surface course shall meet the requirements for Type "C" coarse mix paving mixture according to Item 340, Hot Mix Asphaltic Concrete Pavement (Class A) of the above referenced standard. All other requirements of this document shall be met except density and stability shall be determined by the Marshall Method. The Marshall stability of the mix shall be not less than 1200 pounds when compacted at 75 blows, and have a flow between 8 and 16.

5. INSPECTION

We recommend that all site grading and fill operations be inspected by Danny R. Anderson, Consultants, Inc. Test of fill material should be made at the following rates:

(1) Two field densities per each lift or 1 per 10,000 square feet of fill, according to ASTM D2922 or ASTM D1556.

(2) One moisture density curve for each type of material used, according to ASTM D1557.

(3) One sieve analysis and one plasticity index for each type of imported material used, according to ASTM D422, 423, and 424.

T 8

6. LIMITATIONS

We have made every reasonable effort to properly evaluate the subsurface conditions and the physical properties of the subsoils as revealed by the samples recovered from the borings and the laboratory test results. It must be recognized that the conclusions reached in this report were based on conditions in the eight test borings drilled at the site. Our professional services were performed, our findings obtained, and our recommendations prepared in accordance with generally accepted engineering principles and practices. Should any unusual site conditions exist which appear to vary from those reported herein, we request immediate notification so that further investigations and supplemental recommendations can be made.

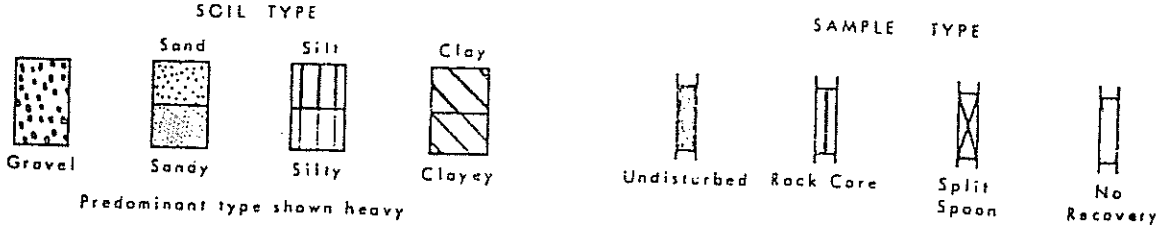
KEY TO SOIL CLASSIFICATIONS AND SYMBOLS



TERMS DESCRIBING CONSISTENCY OR CONDITION

COARSE GRAINED SOILS
(Major portion retained on No. 200 sieve)

Includes (1) clean gravels and sands described as fine, medium or coarse, depending on distribution of grain sizes and (2) silty or clayey gravels and sands. Condition is rated according to relative density, as determined by laboratory tests or estimated from resistance to sampler.

Penetration Resistance Blows/Foot **	Descriptive Term	Relative Density *
0 - 10	Loose	0 to 40%
10 - 30	Medium dense	40 to 70%
30 - 50	Dense	70 to 90%
Over 50	Very dense	90 to 100%

* From tests on undisturbed sand sample
** 140# hammer, 30-inch drop

FINE GRAINED SOILS
(Major portion passing No. 200 sieve)

Includes (1) inorganic and organic silts and clays, (2) gravelly, sandy, or silty clays, and (3) clayey silts. Consistency is rated according to shearing strength, as indicated by penetrometer readings or by unconfined compression tests.

Descriptive Term	Compressive Strength Tons/Sq. Ft.
Very soft	less than 0.25
Soft	0.25 to 0.50
Firm	0.50 to 1.00
Stiff	1.00 to 2.00
Very stiff	2.00 to 4.00
Hard	4.00 and higher

Note: Slickensided and fissured clays may have lower unconfined compressive strengths than shown above, because of planes of weakness or shrinkage cracks in the soil. The consistency ratings of such soils are based on penetrometer readings.

TERMS CHARACTERIZING SOIL STRUCTURE

Slickensided - having inclined planes of weakness that are slick and glossy in appearance

Fissured - containing shrinkage cracks, frequently filled with fine sand or silt; usually more or less vertical

Sensitive - pertaining to cohesive soils that are subject to appreciable loss of strength when remolded

Laminated - composed of thin layers of varying color and texture

Interbedded - composed of alternate layers of different soil types

Calcareous - containing appreciable quantities of calcium carbonate

Well graded - having wide range in grain sizes and substantial amounts of all intermediate particle sizes

Poorly graded - predominantly of one grain size, or having a range of sizes with some intermediate size missing

November 17, 1982

TO WHOM IT MAY CONCERN:

The Eastern Boundary Fault Zone (EBFZ) in the vicinity of the proposed landfill site in northeast El Paso has not surface expression, having been covered by recent piedmont slope deposits and relict landslide blocks. Seismic and gravity profiles across the Hueco Bolson by Matticle (1967) indicate a drop of 25° eastward. Between 20,000 and 25,000 feet of throw would had to have occurred along this fault to account for displacement of strata between the Franklin Mountains and top of the Hueco Formation.

Thus, 400 feet of throw has occurred in the last 1 to 2.5 million years, decreasing in rate. No movement along the EPFZ has been documented since settlement in the El Paso area. For further reference, I would call your attention to the following publications:

Lovejoy, E.M.P., 1975a, An Interpretation of the Structural Geology of the Franklin Mountains, Texas. In: New Mexico Geological Society Guidebook, 26th Field Conference, Las Cruces Country, pp. 261-268.

Lovejoy, E.M.P., 1975b, Cenozoic Tectonics of the El Paso, Texas Region. In: Transactions of the Joint Meeting, Southwest Section of the American Association of Petroleum Geologist and Permian Basin Section of Society of Economic Paleontologists and Mineralogists, Exploration from the Mountains to the Basin, pp. 95-100.

Mattick, Robert E., 1976, A Seismic and Gravity Profile Across the Hueco Bolson, Texas: U.S. Geological Survey Prof. Pag. 575-D, p. D85-D91.

Sayne, A.N., and Livingston, P., 1945, Groundwater Resources of the El Paso Area, Texas. U.S. Geological Survey, Water Supply Paper 919, 140 pp.

If you have any further questions, please feel free to contact me at the Department of Geological Sciences, University of Texas at El Paso, El Paso, Texas 79968 (Phone 915-747-5842).

Sincerely,

Dr. Richard A. Marston

Appendix 3K – Attachment 4
Location Restrictions

SAIC®

SAIC®

Memorandum

To: TCEQ

From: Randall J. Sippel, P.G., SAIC

Subject: Appendix 3K, Attachment 4 – Location Restrictions

Date: March 15, 2013

SAIC Energy, Environment & Infrastructure, LLC (SAIC) has included the site locational restrictions completed by SHB AGRA June 7, 1994 for informational purposes related to previous site characteristics and previous permitting of the facility. Site locational restrictions have been updated to comply with 30 TAC §330, Subchapter M (as they apply to vertical expansions). Information located within this Major Permit Amendment are summarized below:

- 30 TAC §330.543 - Easements and Buffer Zones
  - In accordance to 30 TAC §330.543(a), no solid waste unloading, storage, disposal, or processing operations will occur within any easement, buffer zone, or right-of-way that crosses the facility. The easements are identified on Drawing P2-7 and are discussed in further detail in Section 4.9.6 (text provided for reference below).
  - In accordance to 30 TAC §330.543(b)(2)(B)(D), the vertical expansion utilized a 125-foot buffer zone for the newly permitted airspace. Discussion is provided in Section 4.9.6 (text provided for reference below).

"4.9.6 Easements and Buffer Zones

A 300-ft wide easement, owned by the El Paso Electric Company, is located adjacent and along the northern portion of the Landfill site. The easement is located outside of the permitted Landfill boundary. Contact information for the easement is:

El Paso Electric Company
P.O. Box 982
El Paso, TX 79960
(915) 543-4025 during work hours
(915) 543-5720 or (915) 543-6464 Emergency and after hours

The quarry operation is currently within the permitted Landfill boundary, but will move to the south and then to the adjacent eastern property upon development of future Landfill sectors. The quarry is currently using a 10-ft wide recorded easement, owned by the El Paso Electric Company, which is located north and within the permitted Landfill boundary, for delivery of power. This easement will be abandoned prior to the development of Landfill Sector C. The quarry is also currently using a telephone line located south of the Landfill running in a northern direction along the

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

proposed Landfill sectors. This telephone line will be removed prior to the development of Landfill Sectors E, F, and G. There is no recorded easement for the existing telephone line.

No solid waste unloading, storage, disposal, or processing operations will occur within any easement, buffer zone, or right-of-way that crosses the site. No solid waste disposal will occur within 25 feet of the center line of any utility line or pipeline easement, unless otherwise authorized by the executive director. All pipeline and utility easements will be clearly marked with posts which extend at least six feet above ground level, spaced at intervals no greater than 300 feet.

The buffer zones may vary around the perimeter of the site, but in no case will they be less than 50 feet for previously permitted waste boundaries. For the proposed vertical expansion of the Landfill, the buffer zone is 125-feet from the Landfill boundary in accordance with 30 TAC §330.543(b)(2)(B). All buffer zones, as depicted in the site design, will be clearly marked as specified in Section 4.9.7. Perimeter roads, which provide space for the safe passage and movement of operations and emergency fire fighting and other vehicles, are located within the buffer zone area. Drainage structures, berms, and landscaping as necessary for visual screening are also located in the buffer zone area."

- 30 TAC §330.545 - Airport Safety
  - Airport safety is addressed in Section 2.5.2 (text provided for reference below).

"2.5.2 Airport Safety

Pursuant to 30 TAC §330.61(i)(5), an evaluation of the facility was completed in accordance with 30 TAC §330.545 (a). The identified airports within the general vicinity of the Landfill are provided in Appendix 2A – Maps. The Biggs Army Airfield was identified as being located approximately 9 miles from the Landfill and the El Paso International Airport was identified as being located approximately 11 miles from the Landfill. Additionally, correspondence was submitted to the Federal Aviation Administration to ensure that the Landfill is not:

1. Located within 10,000 feet of any airport runway end used by turbojet aircraft;
2. Within 5,000 feet of any airport runway end used by only piston-type aircraft;
3. Within a six mile radius of any small general service airport runway end used by turbojet or piston-type aircraft; or

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

4. Within a five mile radius of any large general public commercial airport runway end used by turbojet or piston-type aircraft.

Documentation of this correspondence is also provided in Appendix 2C."

- 30 TAC §330.547 - Floodplains
  - Floodplains are addressed in Section 2.9.1 (text provided below for reference).

"2.9.1 Floodplains

According to 40 CFR §258.11**,** 30 TAC §330.307 and §330.547, "owners or operators of new MSWLF units, existing MSWLF units, and lateral expansions located in 100-year floodplains must demonstrate that the unit will not restrict the flow of the 100-year flood, reduce the temporary water storage capacity of the floodplain, or results in washout of solid waste so as to pose a hazard to human health and the environment."

As shown in the Federal Emergency Management Agency (FEMA) Flood Insurance Rate Map (FIRM) provided in Appendix 2E – Floodplains and Wetlands Documentation, a portion of the landfill is located within the 100-year floodplain. No waste disposal activities will occur in the section of the property lying within the 100-year floodplain. Instead, existing Retention Pond A has been designed to cover the area affected by the 100-year floodplain. Refer to Section 3.3 – Facility Surface Water Drainage Report for further details concerning the effects of the 100-year floodplain and the design of the stormwater detention ponds."

- 30 TAC §330.549 - Groundwater
  - Groundwater conditions at the site are described in Section 2.7.1 (text provided below for reference). However, 30 TAC §330.549 does not apply as additional groundwater evaluation is not required for the proposed vertical expansion of this facility.

"2.7.1 Groundwater Conditions

Consistent with §330.61(k)(1), a discussion of groundwater conditions at and near the facility was prepared. Data pertaining to the hydrogeology of the area and groundwater beneath the Landfill are provided in the reports *Site Characterization and Monitoring Plan, McCombs Municipal Landfill, El Paso, Texas* (SHB-AGRA, 1993) included in Appendix 3K, Attachment 1 and *Groundwater Monitoring System Installation, City of El Paso McCombs Landfill* (Raba-Kistner, 2003) included in Appendix 3L, Attachment 1.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

The regional groundwater system in the area primarily consists of the Hueco Bolson aquifers. The Hueco Bolson is divided into the City Artesian area, the Mesa area and the Lower Valley (Leggart, 1962). The Mesa area extends north of the City Artesian area into New Mexico and east to the Hueco Mountains. The Landfill is located within the Mesa area.

Two aquifers occur in these areas: an upper aquifer in the Rio Grande alluvium and a lower aquifer in the Hueco Bolson deposits. Since no known impermeable zone of regional extent separates these aquifers, the Rio Grande alluvium and the Hueco Bolson are considered to be, at least in part, hydrologically connected in the City Artesian and Lower Valley areas (Alvared and Buckner, 1980). The Mesa area primarily consists of Hueco Bolson deposits. Historic withdrawals of groundwater since 1906 for public water supply and irrigation have caused major declines in the water levels. The average water level decline in the Hueco Bolson from 1903 to 1980 is approximately 53 feet (White, 1987).

Locally, recharge to the aquifer occurs due to mountain front infiltration of precipitation from the surface and from the injection of treated sewage into the aquifer from the Hueco Bolson Recharge Project (White and Sladek, 1990). Numerous injection wells were constructed northeast of El Paso and water from the Fred Hervey Water Treatment Plant has been injected into the aquifer by El Paso Water Utilities (EPWU) since the mid-1980s. Since 1991, EPWU has been selling water to El Paso Electric Company for use as cooling water at the Newman Plant, thus less water has been injected into the aquifer (Sperka, 1993).

Based on available information, regional groundwater flow direction in the McCombs Landfill area is to the south-southeast. Groundwater movement in the area is generally less than 1.0 feet per day (White, 1987). EPWU groundwater data indicate that the static groundwater elevation in the area is between 3,670 and 3,675 feet MSL or approximately 370 to 390 feet below ground surface (EPWU, 1993).

Groundwater conditions at the site were determined using data from three groundwater monitoring wells constructed in 2003 around the landfill as part of the approved Subtitle D groundwater monitoring system. Water levels data from December 6, 2010 indicates ground water beneath the site occur approximately 390 to 398 feet below land surface, with corresponding elevations of 3,677 to 3,686 feet AMSI. Based on groundwater level measurements at the site, groundwater flow direction is S70° East or to the east-southeast.

Parkhill, Smith & Copper (PSC) completing an additional hydrogeologic evaluation for the Landfill that included the installation of two additional monitoring wells PZ-4

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

and PZ-5. Data collected from August 2011 through July 2012 indicate groundwater flow direction is predominately to the east/southeast, likely influenced by the drawdown from the Cemex well located near the southeast corner of the landfill and just north of Stan Roberts Road. The PSC report also notes a northwest component of groundwater flow in the southwest portion of the site.

The site-specific groundwater flow direction correlates with regional groundwater flow direction within the Hueco Bolson aquifer."

- 30 TAC §330.551 - Endangered or Threatened Species
  - Section 2.10 addresses endangered species (text is provided for reference below).

"2.10 Endangered Species Statement

To meet the requirements of 30 TAC §330.61(n) and 30 TAC §330.551, a letter dated August 13, 1982 from the United States Fish and Wildlife Service (USFWS) has been included in Appendix 2F – Endangered Species Documentation. This letter was previously included in both the 1984 and 2002 permit amendment application submittals. Additionally, current correspondence between the Texas Parks and Wildlife Department (TPWD) and the U.S. Fish and Wildlife Service is also provided in Appendix 2F.

According to the 1982 USFWS letter, the American Peregrine Falcon may use the project site as a feeding area or pass through the area during migration. According to the information provided on the USFWS website, the American Peregrine Falcon was delisted from the federal endangered species list on August 25, 1999. However, the American Peregrine Falcon remains a State of Texas protected species. A copy of the USFWS species profile is also provided in Appendix 2F – Endangered Species Documentation.

As indicated in the USFWS letter, it is unlikely that the Landfill will have any effect on this species. However, if the American Peregrine Falcon were to be observed within the permitted landfill area, the employees will be instructed to follow the steps listed below:

1. Avoid contact with the bird;
2. Temporarily halt or move site operations to an area away from the bird's location to prevent disrupting the bird's activities while feeding or passing by the site;
3. Wait until the bird abandons the site on its own will; and
4. Resume normal site operations once the bird has taken flight.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

In addition, Landfill personnel will be trained regarding the bird's physical characteristics and appearance in order to be able to identify it at once and with certainty during operations. This training will prevent unnecessary and unwarranted disruptions of site activities due to the presence of birds that may look similar to the American Peregrine Falcon.

According to the 2012 TPWD response letter, the following species have been listed as threatened or endangered under the Endangered Species Act (ESA) and have the potential to occur in El Paso County:

- Least Tern – Listed 08/28/1985
- Northern Aplomado Falcon – Listed 02/25/1986
- Mexican Spotted Owl – Listed 03/16/1993
- Southwestern Willow Flycatcher – Listed 02/27/1995

The following are state-listed threatened species that could potentially occur in the area:

- Texas Horned Lizard
- Mountain Short-Horned Lizard

The following are state-listed species of concern that could potentially occur in the area:

- Western Burrowing Owl
- Desert Night-Blooming Cereus

Further information regarding these species, their suitable habitats, and avoidance procedures are included in Appendix 2F."

- 30 TAC §330.553 – Wetlands
  - Wetlands are addressed in Section 2.9.2 (text is provided below for reference). However, 30 TAC §330.553 does not apply as additional wetland evaluation is not required for the proposed vertical expansion of this facility.

"2.9.2 Wetlands

According to 30 TAC §330.553, new MSW landfill units, lateral expansions, and material recovery operations from a landfill shall not be located in wetlands, unless the owner or operator makes specific demonstrations to show that the landfill will not cause environmental harm.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Based on a 1982 map prepared by T.E. Dohl, the Landfill is not located in area designated as a wetland. This map is included in Attachment 2E – Floodplains and Wetlands Documentation."

- 30 TAC §330.555 - Fault Areas
  - Fault areas are discussed in Section 2.6.4 (text is provided below for reference). However, 30 TAC §330.555 does not apply as additional fault area evaluation is not required for the proposed vertical expansion of this facility.

"2.6.4 Fault Areas[2]

The fault area restriction states that no new landfill units or lateral expansions can be placed within 200 feet of a fault that has experienced Holocene displacement. This restriction provides for minimal setbacks from actual fault traces since faults can result in damage to the landfill's integrity through:

- Movement along the fault causing displacement;
- Seismic activity associated with faulting resulting in seismic shaking of facility structures; and
- Seismic shaking resulting in slope failures.

The original permit states that "…an Eastern Boundary Fault Zone exists between the Franklin Mountains and the Hueco Bolson deposits" and "…assuming continuous movement this (movement of the fault) would equate to approximately 0.005 inches per year" (DRA, 1984).

Since several Quaternary faults have been identified within and at the margins of the Hueco Bolson, SHB reviewed recent published geologic mapping and literature to evaluate the proximity and age of known faults in the vicinity of the McCombs Landfill.

Numerous fault scarps of Quaternary age are preset in the Hueco Bolson near the Landfill. One inferred scarp apparently traverses the northeastern quadrant of the Landfill permit area (SHB, 1993). This fault was not identified on the geologic map prepared by Harbour (1972). Insufficient information is available to confirm or refute the presence of the fault. This fault is more than 200 feet from any existing or proposed Landfill units. Other north-south trending scarps are also apparent in the area.

The age of faulting in Hueco Bolson has been dated as less than 0.5 million years (m.y.), based on offset in the Camp Rice Formation and in soils formed on the Camp Rice formation (Seager 1980). A report by Collins and Raney (1991), indicates that

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

those faults near the site displace deposits of middle Pliestocene age (approximately 200,000 to 900,000 years old). Evidence of displacement of younger deposits have not been documented either because younger sediments do not exist along the fault traces or have been covered by windblown sand. Collins and Raney (1991) point out that movement on the basin bounding the East Franklin Mountains located a few miles to the west of the landfill may be as young as Holocene. Other basin bounding faults and some of the intragraben faults (such as those near the Landfill) most recently experienced rupture during the middle to late Pliestocene. More precise dating of the faults has not been performed, however, it is apparent that the faults have recurrence intervals of more than 10,000 years; otherwise the fault traces would be more clearly defined."

- 30 TAC §330.557 - Seismic Impact Zones
  - Seismic impact zones are discussed in Section 2.6.5 (text is provided below for reference). However, 30 TAC §330.557 does not apply as additional seismic impacts zone evaluation is not required for the proposed vertical expansion of this facility.

"2.6.5 Seismic Impact Zones[2]

The seismic impact zone restrictions (30 TAC §330.557) states that "New municipal solid waste landfill (MSWLF) units and lateral expansions shall not located in seismic impact zones, unless the owner or operator demonstrates to the Director that all containment structures, including liners, leachate collection systems, and surface water control systems, are designed to resist the maximum horizontal acceleration in lithified earth materials for the site."

Under this regulation, a seismic risk zone is considered to be an area that has a 10 percent or more probability that the maximum horizontal acceleration in lithified material, expressed as a percentage of the earth's gravitational pull (g), will not exceed 0.10g in 250 years.

This regulation pertains to new MSWLF units and lateral expansions. This permit modification is a vertical expansion of the existing permitted Landfill and no new horizontal area will be opened under this permit modification. Based on the work completed by SHB-AGRA (1994) a review of USGS Miscellaneous Field Study Map MF-2121, "Probabilistic Earthquake Acceleration and Velocity Maps for the United States and Puerto Rico", (Algermissen, et. al, 1991) was conducted. El Paso County (and the Landfill) fall outside of any designated seismic impact zone.

The map on Figure 2-1 is from the USGS website:

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

http://earthquake.usgs.gov/hazards/apps/map/

Based on 2008 revised data, this map demonstrates the facility is located within a seismic impact zone and exceeds the 30 TAC §330.557 standard of 10 percent or more probability. The seismic impact zone restrictions only apply to new MSWLF units and lateral expansions. The permit modification for the Landfill is for a vertical expansion and no previously-undisturbed earth will be added to the Landfill boundary.

The acreage within the proposed facility boundary was increased for this permit amendment from 327.29 to 346.74 acres at the request of the TCEQ to reflect the existing Landfill buildings and retention ponds that were submitted and approved by the TCEQ under Permit Amendment 729A. These features included existing buildings associated with the landfill operations on property previously leased and now owned by the City of El Paso. Retention ponds within this area were designed by Moreno Cardenas, Inc. to handle runoff from existing buildings and infrastructure (Permit Amendment 729-A, December 2010) in accordance with the applicable codes in place at that time.

- 30 TAC §330.559 - Unstable areas
  - Unstable areas are addressed in Section 2.6.6 (text is provided below for reference).

"2.6.6 Unstable Areas

Consistent with 330.61(j)(4) and 330.559, unstable areas documentation was prepared and part of the application to demonstrate that the Landfill meets the location restriction for unstable area.

TCEQ regulations require the owner or operators of new MSWLF units, existing MSWLF units and lateral expansions located in an unstable area shall demonstrate that engineering measures have been incorporated into the MSWLF unit's design to ensure that the integrity of the structural components of the MSWLF unit will not be disrupted.

An unstable area is defined by TCEQ as a location that is susceptible to natural or human-induced events or forces capable of impairing the integrity of some or all of the landfill's structural components responsible for preventing releases from a landfill. An unstable area can exhibit poor foundation conditions, area susceptible to mass movement, and karst terrains.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

2.6.6.1 Unstable Slopes

No landslide deposits in the vicinity of the Landfill are shown on any published geologic information and none have been identified during site visits (SHB-AGRA, 1994).

2.6.6.2 Karst

Several thousand feet of basin filling sediments occur beneath the Landfill. No limestone or other soluble units subject to karst formation exists in the vicinity (SHB-AGRA, 1994).

2.6.6.3 Subsidence

Subsidence has been documented in the El Paso metropolitan area as a result of groundwater withdrawal and subsequent decline in groundwater levels, especially in area having thick accumulations of clay in the subsurface. The Landfill is located in an area of documented groundwater withdrawal resulting in groundwater declines up to 40 feet (Ashworth 1990). No land surface subsidence has been documented in the vicinity of the Landfill (Land and Armstrong, 1985). Due to depth to groundwater, formation of large scale subsidence features is not anticipated, but cannot be precluded (SHB-AGRA, 1994)

2.6.6.4 Liquefaction

Since groundwater occurs at depths of 300-400 feet below land surface, no liquefaction concerns exist (SHB-AGRA, 1994)."

- 30 TAC §330.561 - Coastal Areas is not applicable to this facility.
- 30 TAC §330.563 - Type I and IV Landfill Permit Issuance Prohibited
  - 30 TAC §330.563 does not apply to vertical expansions of landfills.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

SAIC®

Memorandum

To: TCEQ

From: Randall J. Sippel, P.G., SAIC

Subject: Appendix 3K, Attachment 4 – Location Restrictions

Date: March 15, 2013

SAIC Energy, Environment & Infrastructure, LLC (SAIC) has included the site locational restrictions completed by SHB AGRA June 7, 1994 for informational purposes related to previous site characteristics and previous permitting of the facility. Site locational restrictions have been updated to comply with 30 TAC §330, Subchapter M (as they apply to vertical expansions). Information located within this Major Permit Amendment are summarized below:

- 30 TAC §330.543 - Easements and Buffer Zones
  - In accordance to 30 TAC §330.543(a), no solid waste unloading, storage, disposal, or processing operations will occur within any easement, buffer zone, or right-of-way that crosses the facility. The easements are identified on Drawing P2-7 and are discussed in further detail in Section 4.9.6 (text provided for reference below).
  - In accordance to 30 TAC §330.543(b)(2)(B)(D), the vertical expansion utilized a 125-foot buffer zone for the newly permitted airspace. Discussion is provided in Section 4.9.6 (text provided for reference below).

"4.9.6 Easements and Buffer Zones

A 300-ft wide easement, owned by the El Paso Electric Company, is located adjacent and along the northern portion of the Landfill site. The easement is located outside of the permitted Landfill boundary. Contact information for the easement is:

El Paso Electric Company
P.O. Box 982
El Paso, TX 79960
(915) 543-4025 during work hours
(915) 543-5720 or (915) 543-6464 Emergency and after hours

The quarry operation is currently within the permitted Landfill boundary, but will move to the south and then to the adjacent eastern property upon development of future Landfill sectors. The quarry is currently using a 10-ft wide recorded easement, owned by the El Paso Electric Company, which is located north and within the permitted Landfill boundary, for delivery of power. This easement will be abandoned prior to the development of Landfill Sector C. The quarry is also currently using a telephone line located south of the Landfill running in a northern direction along the

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

proposed Landfill sectors. This telephone line will be removed prior to the development of Landfill Sectors E, F, and G. There is no recorded easement for the existing telephone line.

No solid waste unloading, storage, disposal, or processing operations will occur within any easement, buffer zone, or right-of-way that crosses the site. No solid waste disposal will occur within 25 feet of the center line of any utility line or pipeline easement, unless otherwise authorized by the executive director. All pipeline and utility easements will be clearly marked with posts which extend at least six feet above ground level, spaced at intervals no greater than 300 feet.

The buffer zones may vary around the perimeter of the site, but in no case will they be less than 50 feet for previously permitted waste boundaries. For the proposed vertical expansion of the Landfill, the buffer zone is 125-feet from the Landfill boundary in accordance with 30 TAC §330.543(b)(2)(B). All buffer zones, as depicted in the site design, will be clearly marked as specified in Section 4.9.7. Perimeter roads, which provide space for the safe passage and movement of operations and emergency fire fighting and other vehicles, are located within the buffer zone area. Drainage structures, berms, and landscaping as necessary for visual screening are also located in the buffer zone area."

- 30 TAC §330.545 - Airport Safety
  - Airport safety is addressed in Section 2.5.2 (text provided for reference below).

"2.5.2 Airport Safety

Pursuant to 30 TAC §330.61(i)(5), an evaluation of the facility was completed in accordance with 30 TAC §330.545 (a). The identified airports within the general vicinity of the Landfill are provided in Appendix 2A – Maps. The Biggs Army Airfield was identified as being located approximately 9 miles from the Landfill and the El Paso International Airport was identified as being located approximately 11 miles from the Landfill. Additionally, correspondence was submitted to the Federal Aviation Administration to ensure that the Landfill is not:

1. Located within 10,000 feet of any airport runway end used by turbojet aircraft;
2. Within 5,000 feet of any airport runway end used by only piston-type aircraft;
3. Within a six mile radius of any small general service airport runway end used by turbojet or piston-type aircraft; or

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

4. Within a five mile radius of any large general public commercial airport runway end used by turbojet or piston-type aircraft.

Documentation of this correspondence is also provided in Appendix 2C."

- 30 TAC §330.547 - Floodplains
  - Floodplains are addressed in Section 2.9.1 (text provided below for reference).

"2.9.1 Floodplains

According to 40 CFR §258.11**,** 30 TAC §330.307 and §330.547, "owners or operators of new MSWLF units, existing MSWLF units, and lateral expansions located in 100-year floodplains must demonstrate that the unit will not restrict the flow of the 100-year flood, reduce the temporary water storage capacity of the floodplain, or results in washout of solid waste so as to pose a hazard to human health and the environment."

As shown in the Federal Emergency Management Agency (FEMA) Flood Insurance Rate Map (FIRM) provided in Appendix 2E – Floodplains and Wetlands Documentation, a portion of the landfill is located within the 100-year floodplain. No waste disposal activities will occur in the section of the property lying within the 100-year floodplain. Instead, existing Retention Pond A has been designed to cover the area affected by the 100-year floodplain. Refer to Section 3.3 – Facility Surface Water Drainage Report for further details concerning the effects of the 100-year floodplain and the design of the stormwater detention ponds."

- 30 TAC §330.549 - Groundwater
  - Groundwater conditions at the site are described in Section 2.7.1 (text provided below for reference). However, 30 TAC §330.549 does not apply as additional groundwater evaluation is not required for the proposed vertical expansion of this facility.

"2.7.1 Groundwater Conditions

Consistent with §330.61(k)(1), a discussion of groundwater conditions at and near the facility was prepared. Data pertaining to the hydrogeology of the area and groundwater beneath the Landfill are provided in the reports *Site Characterization and Monitoring Plan, McCombs Municipal Landfill, El Paso, Texas* (SHB-AGRA, 1993) included in Appendix 3K, Attachment 1 and *Groundwater Monitoring System Installation, City of El Paso McCombs Landfill* (Raba-Kistner, 2003) included in Appendix 3L, Attachment 1.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

The regional groundwater system in the area primarily consists of the Hueco Bolson aquifers. The Hueco Bolson is divided into the City Artesian area, the Mesa area and the Lower Valley (Leggart, 1962). The Mesa area extends north of the City Artesian area into New Mexico and east to the Hueco Mountains. The Landfill is located within the Mesa area.

Two aquifers occur in these areas: an upper aquifer in the Rio Grande alluvium and a lower aquifer in the Hueco Bolson deposits. Since no known impermeable zone of regional extent separates these aquifers, the Rio Grande alluvium and the Hueco Bolson are considered to be, at least in part, hydrologically connected in the City Artesian and Lower Valley areas (Alvared and Buckner, 1980). The Mesa area primarily consists of Hueco Bolson deposits. Historic withdrawals of groundwater since 1906 for public water supply and irrigation have caused major declines in the water levels. The average water level decline in the Hueco Bolson from 1903 to 1980 is approximately 53 feet (White, 1987).

Locally, recharge to the aquifer occurs due to mountain front infiltration of precipitation from the surface and from the injection of treated sewage into the aquifer from the Hueco Bolson Recharge Project (White and Sladek, 1990). Numerous injection wells were constructed northeast of El Paso and water from the Fred Hervey Water Treatment Plant has been injected into the aquifer by El Paso Water Utilities (EPWU) since the mid-1980s. Since 1991, EPWU has been selling water to El Paso Electric Company for use as cooling water at the Newman Plant, thus less water has been injected into the aquifer (Sperka, 1993).

Based on available information, regional groundwater flow direction in the McCombs Landfill area is to the south-southeast. Groundwater movement in the area is generally less than 1.0 feet per day (White, 1987). EPWU groundwater data indicate that the static groundwater elevation in the area is between 3,670 and 3,675 feet MSL or approximately 370 to 390 feet below ground surface (EPWU, 1993).

Groundwater conditions at the site were determined using data from three groundwater monitoring wells constructed in 2003 around the landfill as part of the approved Subtitle D groundwater monitoring system. Water levels data from December 6, 2010 indicates ground water beneath the site occur approximately 390 to 398 feet below land surface, with corresponding elevations of 3,677 to 3,686 feet AMSI. Based on groundwater level measurements at the site, groundwater flow direction is S70° East or to the east-southeast.

Parkhill, Smith & Copper (PSC) completing an additional hydrogeologic evaluation for the Landfill that included the installation of two additional monitoring wells PZ-4

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

and PZ-5. Data collected from August 2011 through July 2012 indicate groundwater flow direction is predominately to the east/southeast, likely influenced by the drawdown from the Cemex well located near the southeast corner of the landfill and just north of Stan Roberts Road. The PSC report also notes a northwest component of groundwater flow in the southwest portion of the site.

The site-specific groundwater flow direction correlates with regional groundwater flow direction within the Hueco Bolson aquifer."

- 30 TAC §330.551 - Endangered or Threatened Species
  - Section 2.10 addresses endangered species (text is provided for reference below).

"2.10 Endangered Species Statement

To meet the requirements of 30 TAC §330.61(n) and 30 TAC §330.551, a letter dated August 13, 1982 from the United States Fish and Wildlife Service (USFWS) has been included in Appendix 2F – Endangered Species Documentation. This letter was previously included in both the 1984 and 2002 permit amendment application submittals. Additionally, current correspondence between the Texas Parks and Wildlife Department (TPWD) and the U.S. Fish and Wildlife Service is also provided in Appendix 2F.

According to the 1982 USFWS letter, the American Peregrine Falcon may use the project site as a feeding area or pass through the area during migration. According to the information provided on the USFWS website, the American Peregrine Falcon was delisted from the federal endangered species list on August 25, 1999. However, the American Peregrine Falcon remains a State of Texas protected species. A copy of the USFWS species profile is also provided in Appendix 2F – Endangered Species Documentation.

As indicated in the USFWS letter, it is unlikely that the Landfill will have any effect on this species. However, if the American Peregrine Falcon were to be observed within the permitted landfill area, the employees will be instructed to follow the steps listed below:

1. Avoid contact with the bird;
2. Temporarily halt or move site operations to an area away from the bird's location to prevent disrupting the bird's activities while feeding or passing by the site;
3. Wait until the bird abandons the site on its own will; and
4. Resume normal site operations once the bird has taken flight.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

In addition, Landfill personnel will be trained regarding the bird's physical characteristics and appearance in order to be able to identify it at once and with certainty during operations. This training will prevent unnecessary and unwarranted disruptions of site activities due to the presence of birds that may look similar to the American Peregrine Falcon.

According to the 2012 TPWD response letter, the following species have been listed as threatened or endangered under the Endangered Species Act (ESA) and have the potential to occur in El Paso County:

- Least Tern – Listed 08/28/1985
- Northern Aplomado Falcon – Listed 02/25/1986
- Mexican Spotted Owl – Listed 03/16/1993
- Southwestern Willow Flycatcher – Listed 02/27/1995

The following are state-listed threatened species that could potentially occur in the area:

- Texas Horned Lizard
- Mountain Short-Horned Lizard

The following are state-listed species of concern that could potentially occur in the area:

- Western Burrowing Owl
- Desert Night-Blooming Cereus

Further information regarding these species, their suitable habitats, and avoidance procedures are included in Appendix 2F."

- 30 TAC §330.553 – Wetlands
  - Wetlands are addressed in Section 2.9.2 (text is provided below for reference). However, 30 TAC §330.553 does not apply as additional wetland evaluation is not required for the proposed vertical expansion of this facility.

"2.9.2 Wetlands

According to 30 TAC §330.553, new MSW landfill units, lateral expansions, and material recovery operations from a landfill shall not be located in wetlands, unless the owner or operator makes specific demonstrations to show that the landfill will not cause environmental harm.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

Based on a 1982 map prepared by T.E. Dohl, the Landfill is not located in area designated as a wetland. This map is included in Attachment 2E – Floodplains and Wetlands Documentation."

- 30 TAC §330.555 - Fault Areas
  - Fault areas are discussed in Section 2.6.4 (text is provided below for reference). However, 30 TAC §330.555 does not apply as additional fault area evaluation is not required for the proposed vertical expansion of this facility.

"2.6.4 Fault Areas[2]

The fault area restriction states that no new landfill units or lateral expansions can be placed within 200 feet of a fault that has experienced Holocene displacement. This restriction provides for minimal setbacks from actual fault traces since faults can result in damage to the landfill's integrity through:

- Movement along the fault causing displacement;
- Seismic activity associated with faulting resulting in seismic shaking of facility structures; and
- Seismic shaking resulting in slope failures.

The original permit states that "…an Eastern Boundary Fault Zone exists between the Franklin Mountains and the Hueco Bolson deposits" and "…assuming continuous movement this (movement of the fault) would equate to approximately 0.005 inches per year" (DRA, 1984).

Since several Quaternary faults have been identified within and at the margins of the Hueco Bolson, SHB reviewed recent published geologic mapping and literature to evaluate the proximity and age of known faults in the vicinity of the McCombs Landfill.

Numerous fault scarps of Quaternary age are preset in the Hueco Bolson near the Landfill. One inferred scarp apparently traverses the northeastern quadrant of the Landfill permit area (SHB, 1993). This fault was not identified on the geologic map prepared by Harbour (1972). Insufficient information is available to confirm or refute the presence of the fault. This fault is more than 200 feet from any existing or proposed Landfill units. Other north-south trending scarps are also apparent in the area.

The age of faulting in Hueco Bolson has been dated as less than 0.5 million years (m.y.), based on offset in the Camp Rice Formation and in soils formed on the Camp Rice formation (Seager 1980). A report by Collins and Raney (1991), indicates that

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

those faults near the site displace deposits of middle Pliestocene age (approximately 200,000 to 900,000 years old). Evidence of displacement of younger deposits have not been documented either because younger sediments do not exist along the fault traces or have been covered by windblown sand. Collins and Raney (1991) point out that movement on the basin bounding the East Franklin Mountains located a few miles to the west of the landfill may be as young as Holocene. Other basin bounding faults and some of the intragraben faults (such as those near the Landfill) most recently experienced rupture during the middle to late Pliestocene. More precise dating of the faults has not been performed, however, it is apparent that the faults have recurrence intervals of more than 10,000 years; otherwise the fault traces would be more clearly defined."

- 30 TAC §330.557 - Seismic Impact Zones
  - Seismic impact zones are discussed in Section 2.6.5 (text is provided below for reference). However, 30 TAC §330.557 does not apply as additional seismic impacts zone evaluation is not required for the proposed vertical expansion of this facility.

"2.6.5 Seismic Impact Zones[2]

The seismic impact zone restrictions ***(30 TAC §330.557)*** states that "New municipal solid waste landfill (MSWLF) units and lateral expansions shall not located in seismic impact zones, unless the owner or operator demonstrates to the Director that all containment structures, including liners, leachate collection systems, and surface water control systems, are designed to resist the maximum horizontal acceleration in lithified earth materials for the site."

Under this regulation, a seismic risk zone is considered to be an area that has a 10 percent or more probability that the maximum horizontal acceleration in lithified material, expressed as a percentage of the earth's gravitational pull (g), will not exceed 0.10g in 250 years.

This regulation pertains to new MSWLF units and lateral expansions. This permit modification is a vertical expansion of the existing permitted Landfill and no new horizontal area will be opened under this permit modification. Based on the work completed by SHB-AGRA (1994) a review of USGS Miscellaneous Field Study Map MF-2121, "Probabilistic Earthquake Acceleration and Velocity Maps for the United States and Puerto Rico", (Algermissen, et. al, 1991) was conducted. El Paso County (and the Landfill) fall outside of any designated seismic impact zone.

The map on Figure 2-1 is from the USGS website:

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

http://earthquake.usgs.gov/hazards/apps/map/

Based on 2008 revised data, this map demonstrates the facility is located within a seismic impact zone and exceeds the 30 TAC §330.557 standard of 10 percent or more probability. The seismic impact zone restrictions only apply to new MSWLF units and lateral expansions. The permit modification for the Landfill is for a vertical expansion and no previously-undisturbed earth will be added to the Landfill boundary.

The acreage within the proposed facility boundary was increased for this permit amendment from 327.29 to 346.74 acres at the request of the TCEQ to reflect the existing Landfill buildings and retention ponds that were submitted and approved by the TCEQ under Permit Amendment 729A. These features included existing buildings associated with the landfill operations on property previously leased and now owned by the City of El Paso. Retention ponds within this area were designed by Moreno Cardenas, Inc. to handle runoff from existing buildings and infrastructure (Permit Amendment 729-A, December 2010) in accordance with the applicable codes in place at that time.

- 30 TAC §330.559 - Unstable areas
  - Unstable areas are addressed in Section 2.6.6 (text is provided below for reference).

"2.6.6 Unstable Areas

Consistent with 330.61(j)(4) and 330.559, unstable areas documentation was prepared and part of the application to demonstrate that the Landfill meets the location restriction for unstable area.

TCEQ regulations require the owner or operators of new MSWLF units, existing MSWLF units and lateral expansions located in an unstable area shall demonstrate that engineering measures have been incorporated into the MSWLF unit's design to ensure that the integrity of the structural components of the MSWLF unit will not be disrupted.

An unstable area is defined by TCEQ as a location that is susceptible to natural or human-induced events or forces capable of impairing the integrity of some or all of the landfill's structural components responsible for preventing releases from a landfill. An unstable area can exhibit poor foundation conditions, area susceptible to mass movement, and karst terrains.

SAIC Energy, Environment & Infrastructure, LLC
1380 Corporate Center Curve, Suite 305 | St. Paul, MN 55121 | tel: 651.994.8415 | fax: 651.994.8396 | saic.com/EEandI

2.6.6.1 Unstable Slopes

No landslide deposits in the vicinity of the Landfill are shown on any published geologic information and none have been identified during site visits (SHB-AGRA, 1994).

2.6.6.2 Karst

Several thousand feet of basin filling sediments occur beneath the Landfill. No limestone or other soluble units subject to karst formation exists in the vicinity (SHB-AGRA, 1994).

2.6.6.3 Subsidence

Subsidence has been documented in the El Paso metropolitan area as a result of groundwater withdrawal and subsequent decline in groundwater levels, especially in area having thick accumulations of clay in the subsurface. The Landfill is located in an area of documented groundwater withdrawal resulting in groundwater declines up to 40 feet (Ashworth 1990). No land surface subsidence has been documented in the vicinity of the Landfill (Land and Armstrong, 1985). Due to depth to groundwater, formation of large scale subsidence features is not anticipated, but cannot be precluded (SHB-AGRA, 1994)

2.6.6.4 Liquefaction

Since groundwater occurs at depths of 300-400 feet below land surface, no liquefaction concerns exist (SHB-AGRA, 1994)."

- 30 TAC §330.561 - Coastal Areas is not applicable to this facility.
- 30 TAC §330.563 - Type I and IV Landfill Permit Issuance Prohibited
  - 30 TAC §330.563 does not apply to vertical expansions of landfills.

Re: City of El Paso
McCombs Municipal Solid Waste Landfill
MSW Permit No. 729A
Location Restrictions

Dear Mr. Cordova:

On June 20, 1994, the Texas Natural Resource Conservation Commission (TNRCC) received the certification of the demonstration of the location restrictions, pursuant to 30 Texas Administrative Code Section 330 Subchapter L, for the above-referenced facility. Based on a review of the information presented and the information contained within the TNRCC Central Records files, it appears that this facility meets the requirements of the demonstration of the location restrictions.

Please place individual certifications, signed by both the preparer of the location demonstration and the site operator, this letter, and the demonstration of the location restrictions within the facility's Site Operating Record.

If you have any questions concerning this letter, please contact Susan Janek, P.E. at (512) 239-6674.

Sincerely,

Susan Janek

EXECUTIVE SUMMARY

An evaluation of potential landfill restrictions associated with the McCombs Municipal Landfill was completed by SHB AGRA, Inc. This evaluation was completed to comply with EPA and TNRCC requirements set forth in 40 CFR Part 258, Subpart B and in Chapter 31 of the Texas Administration Code, Sections 330.250 (b) and Subchapter L.

To achieve project goals, the evaluation included a review of existing geotechnical, geological, topographic and hydrologic data for the site. In addition, the relative locations of airports and from the landfill were evaluated.

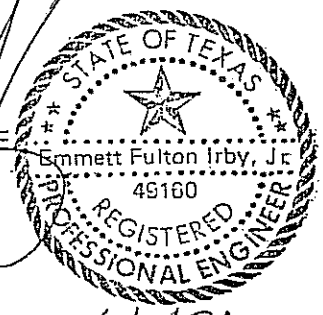
The results of our evaluation suggest the McCombs Municipal Landfill is not subject to restrictsions due to the presence of floodplains, wetlands, seismic zones or unstable areas. The site is not subject to restrictions due to the presence of nearby airports.

Several faults of Quaternary age are known in the immediate landfill vicinity. No evidence for Holocene displacement has been observed on known fault traces.

CERTIFICATION

I, Emmett F. Irby, Jr.,P.E., do hereby certify that the documentation presented in the attached document, "Evaluation of Location Restrictions, McCombs Municipal Landfill, dated June 7, 1994, does to the best of my knowledge, accurately reflect the conditions at the landfill as they pertain to landfill location restrictions stipulated in 31 TAC 330.250(b) and in Subchapter L.

Emmett F. Irby, Jr., P.E.



6/7/94

1. INTRODUCTION

1.1 BACKGROUND

An evaluation of location restrictions for the McCombs Municipal Landfill was conducted by SHB AGRA, Inc. to comply with requirements specified by the U.S. Environmental Protection Agency (EPA) as adopted by the Texas Natural Resource Conservation Commission (TNRCC).

The EPA's Subtitle D, Part 258, Subpart B and the State of Texas' adaptation of these guidelines in 31 Texas Administrative Code (TAC) Section 330.250(b) specify an evaluation and demonstration of location restrictions to address both the potential effects that a municipal solid waste landfill (MSWLF) may have on the surrounding environment, and the effects that natural and man-made conditions may have on the performance of a landfill unit. Pursuant to these guidelines, "the owner or operator of all existing MSWLF units or lateral expansions at a facility shall submit to the Executive Director of the TNRCC for review and approval a certification of compliance with (the appropriate guidelines for) Airport Safety, Floodplain(s), and Unstable Areas."

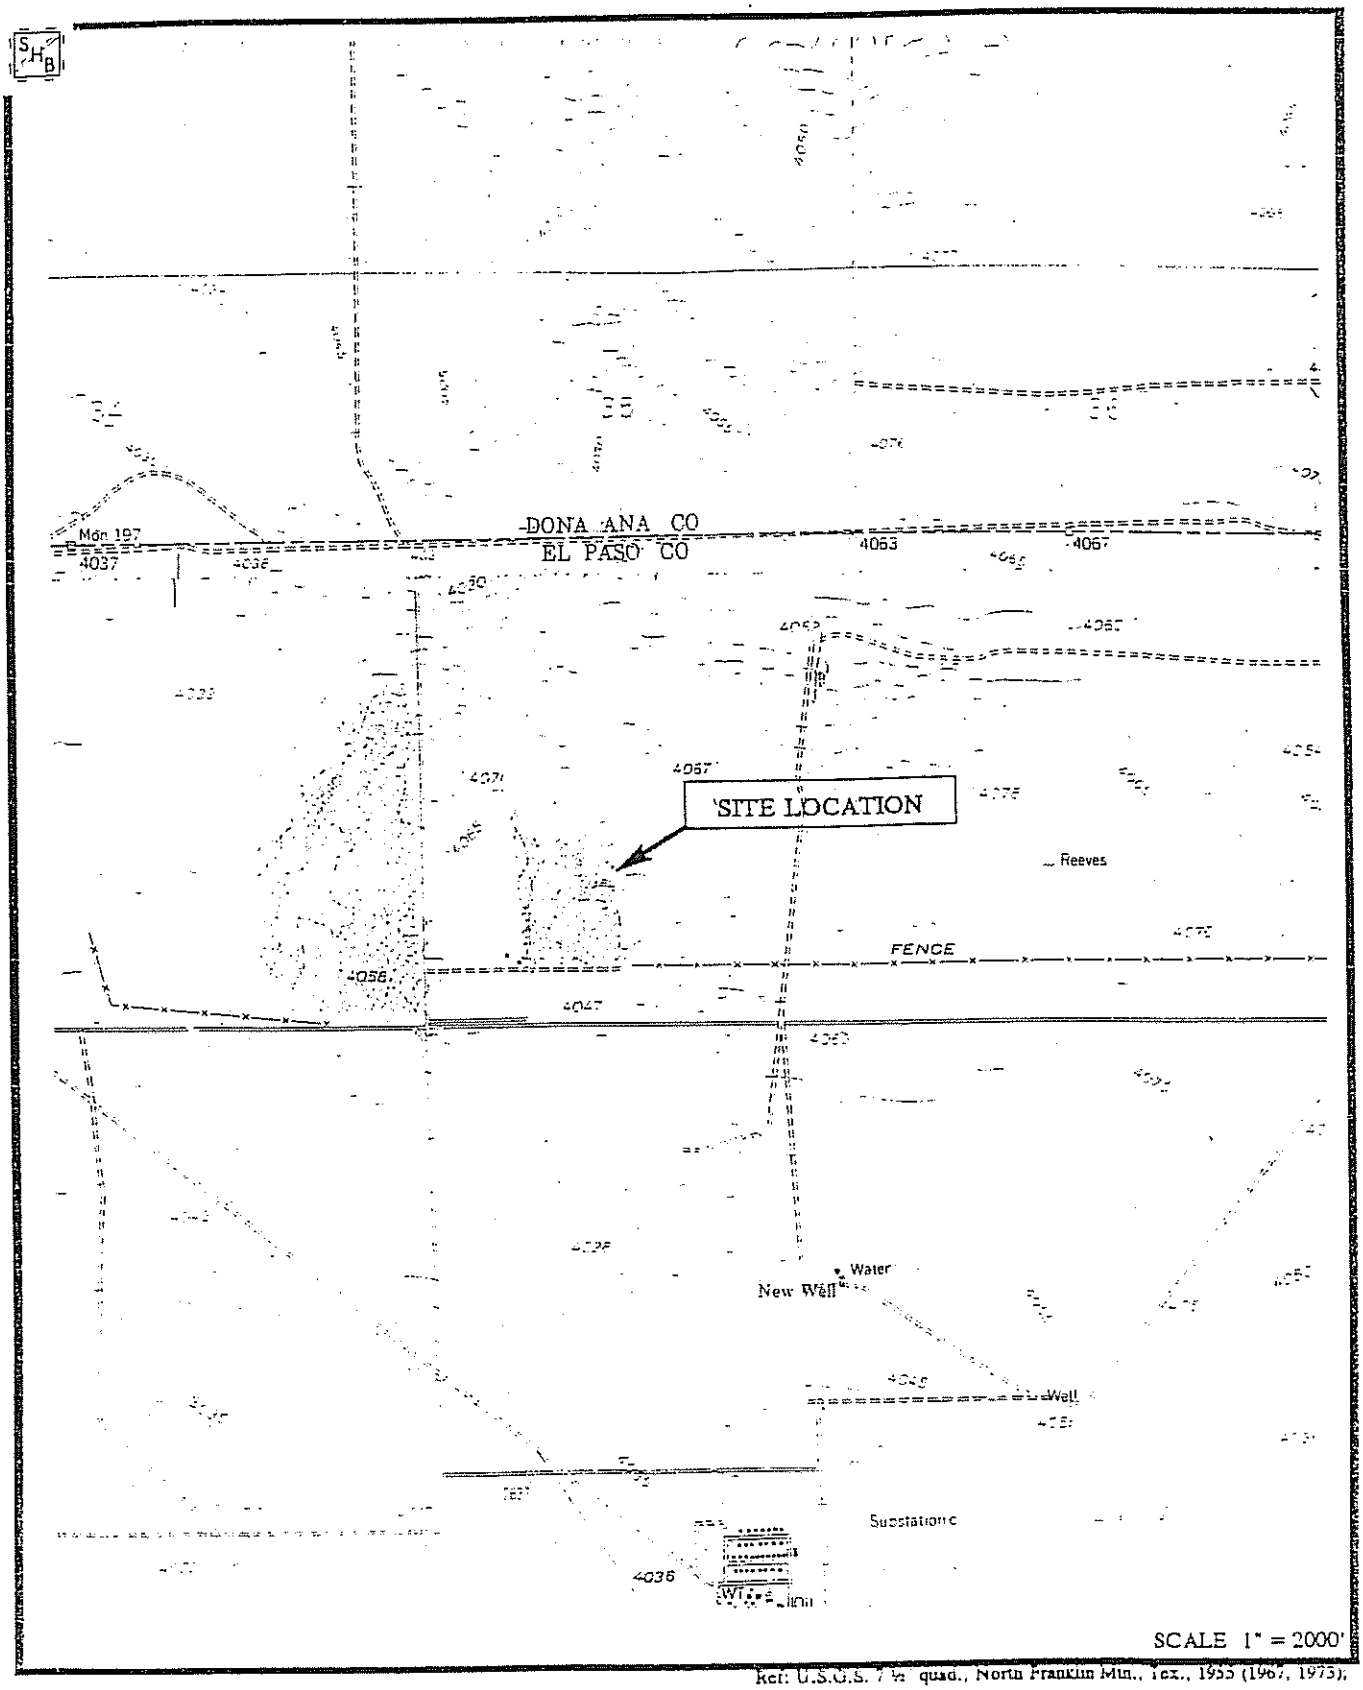
In summary these location restrictions state that existing MSWLF's within 10,000 feet of the end of any runway used by turbojet aircraft or within 5000 feet of runways used only by piston-type aircraft must demonstrate that the MSWLF does not pose a bird hazard to aircraft. Existing MSWLF's may not restrict the flow of the 100-year flood, reduce the temporary water storage capacity of the floodplain, or result in the washout of solid waste so as to pose a hazard to human health or the environment. Existing MSWLF's in unstable areas must demonstrate that the structural components of the MSWLF can withstand the impacts of events such as landslides, unstable slopes, karst areas, etc.

Existing MSWLF's that cannot establish the airport safety, floodplain or unstable area demonstrations are required to close the MSWLF by October, 1996, unless the State Director extends the deadline.

It is the intent of this document to be a modification of existing Permit No. 729A, and to be made part of the permanent permit files. A copy of this document, plus any correspondence between the City and the TNRCC, as well as final approval of the certification shall be made part of the permanent Site Operating Record of the landfill.

1.2 PROJECT LOCATION

The McCombs Landfill is located approximately 20 miles northeast of downtown El Paso in Section 6, Block 80, Township 1, Texas and Pacific Surveys. The landfill is situated at the northeast corner of the intersection of McCombs Road and Farm Road 2529 (see Figure 1). The landfill encompasses approximately 327 acres, although only a portion has been landfilled at present. The City owns and operates the facility. The landfill has been developed in an existing sand and gravel quarry.



Ref: U.S.G.S. 7½' quad., North Franklin Mtn., Tex., 1955 (1967, 1973).

Landfill Restrictions Evaluation
McCombs Landfill
El Paso, Texas
Job No. E94-4082

Figure 1
Site Location Map

AGRA
Earth & Environmental Group

The McCombs Landfill was first permitted by the Texas Department of Health Resources (TDHR) as a Type I Municipal Landfill in 1976. The original permit was for a 25 acre area and for approximately 400 tons per day of municipal solid waste. In 1984, the permit was modified (Permit No. 729 A) to cover an area of approximately 327 acres.

1.3. REVIEW OF ORIGINAL PERMIT APPLICATION

The initial permit application for the McCombs Landfill was completed by DRA on behalf of the City. The permit application addressed site characteristics, and included discussions of the types of wastes to be accepted, and presents pertinent operational and maintenance criteria. Subsurface investigations completed on site were presented in a report that was appended to the permit application.

Applicable sections of the original permit were reviewed to assist in the preparation of this document. This data was supplemented by our review of pertinent EPA and TNRCC guidance documents, publicly available documentation and maps, and a review of published literature for the site and surrounding area.

2. AIRPORT LOCATION RESTRICTIONS

Due to the potential for landfills to attract birds, the Federal Aviation Administration (FAA), has taken the position that when a new MSWLF unit or a lateral expansion is proposed within a 5 mile radius of any airport runway end, the owner or operator of the unit must notify both the affected airport and the FAA to allow for their review of any siting or expansion plans. In addition, MSWLF units within 10,000 feet of any airport runway used by turbojet aircraft or within 5000 feet of any airport runway used by only piston-type aircraft must demonstrate that the landfill unit does not pose a bird hazard to aircraft.

To evaluate this restriction, SHB obtained maps from both the United States Geologic Survey (USGS) and the FAA to identify any airports within 5 miles of the Landfill. No operating airports are currently known to be located within 5 miles of the McCombs Landfill. The nearest air strip to the McCombs Landfill is a private sail plane field (Skyport), more than two miles south-southwest of the landfill location. According to Mr. Antonio Borrego with the Engineering Department of the City of El Paso, this airfield is currently used for flying model aircraft. However, as a precautionary measure, this information is also being forwarded to the Aviation Division of the Department of Transportation for review. Biggs Airfield is approximately 10 miles south-southeast of the site, while the El Paso International Airport is more than 12 miles due south of the Landfill. Locations of the nearest airports with reference to the McCombs Landfill are shown in Figure 2. This information is generally consistent with that provided in the permit application for the facility. No further evaluation of bird hazards appears warranted.

AGRA
Earth & Environmental Group

3. FLOODPLAIN RESTRICTIONS

As stated in 40 CFR section 258.11 and in 30 TAC 330.301, " owners or operators of new MSWLF units, existing MSWLF units and lateral expansions located in 100-year floodplains must demonstrate that the unit will not restrict the flow of the 100-year flood, reduce the temporary water storage capacity of the floodplain, or result in washout of solid waste so as to pose a hazard to human health and the environment."

To evaluate whether the McCombs Landfill lies within a 100-year floodplain, SHB reviewed applicable Federal Emergency Management Agency (FEMA) flood insurance rate maps (FIRMs) for the site and surrounding area. In addition, the original permit application completed for the City in 1983 was reviewed.

The FIRM map shown on Figure 3 indicates that the site does not lie within a designated 100-year floodplain.

4. WETLANDS RESTRICTIONS

Under the existing regulatory framework, new MSWLF units or lateral expansions shall not be located in wetlands. Existing MSWLF units in wetlands may continue operation if they can comply with a variety of state and federal guidelines.

A wetlands is currently defined by the U.S. Army Corps of Engineers (1987) to include a variety swamps, marshes, bogs and other inundated or saturated areas where certain hydric soils, hydrophylic vegetation and wetland hydrology criteria are met.

Based on published information (Dohl, 1982), the McCombs Landfill does not impinge and is not adjacent to a designated wetland (See Figure 4). Supporting documentation with the permit application quotes the Department of the Interior Fish and Wildlife Service as stating that two listed endangered species - the Peregrine Falcon and Sneed's Pincushion Cactus - are known to exist in El Paso County. However, neither of these two species were found within the project area.

5. FAULT AREAS

The fault area restriction states that no new landfill units or lateral expansions can be placed within 200 feet of a fault that has experienced Holocene displacement. This restriction provides for minimal setbacks from actual fault traces since faults can result in damage to the landfill's integrity though:

- movement along the fault causing displacement.
- seismic activity associated with faulting resulting in seismic shaking of facility structures.
- seismic shaking resulting in slope failures.

The original permit states that "...an Eastern Boundary Fault Zone exists between the Franklin Mountains and the Hueco Bolson deposits.", and "...assuming continuous movement this (movement of the fault) would equate to approximately 0.005 inches per year" (DRA, 1984).

Since several Quaternary faults have been identified within and at the margins of the Hueco Bolson, SHB reviewed recent published geologic mapping and literature to evaluate the proximity and age of known faults in the vicinity of the McCombs Landfill.

Numerous fault scarps of Quaternary age are present in the Hueco Bolson near the landfill. One inferred scarp apparently traverses the northeastern quadrant of the landfill permit area (SHB, 1993). This fault was not identified on the geologic map prepared by Harbour (1972). Insufficient information is available to confirm or refute the presence of the fault. This fault is more than 200 feet from any existing or proposed landfill units. Other north-south trending scarps are also apparent in the area. These faults are shown on Figure 5.

The age of faulting in Hueco Bolson has been dated as less than 0.5 m.y., based on offset in the Camp Rice Formation and in soils formed on the Camp Rice formation (Seager, 1980). A report by Collins and Raney, (1991), indicates that those faults near the site displace deposits of middle Pleistocene age (approximately 200,000 to 900,000 years old). Evidence of displacement of younger deposits have not been documented either because younger sediments do not exist along the fault traces or have been covered by windblown sand. Collins and Raney (1991) point out that movement on the basin bounding East Franklin Mountains located a few miles to the west of the landfill may be as young as Holocene. Other basin bounding faults and some of the intragraben faults (such as those near the landfill) most recently experienced rupture during the middle to late Pleistocene. More precise dating of the faults has not been performed, however, it is apparent that the faults have recurrence intervals of more than 10,000 years, otherwise the fault traces would be more clearly defined.

Figure 5
Faults Location Map

AGRA
Earth & Environmental Group

Future development to the northern limits of the permit area will have to include either a detailed fault study or the incorporation of additional safety measures into the design. It is also considered prudent to design for fault contingencies in any new cell design.

6. SEISMIC IMPACT ZONES

The seismic impact zone restriction states that "New MSWLF units and lateral expansions shall not be located in seismic impact zones, unless the owner or operator demonstrates to the Director that all containment structures, including liners, leachate collection systems, and surface water control systems, are designed to resist the maximum horizontal acceleration in lithified earth material for the site."

Under this regulation, a seismic risk zone is considered to be an area that has a 10 percent or more probability that the maximum horizontal acceleration in lithified material, expressed as a percentage of the earth's gravitational pull (g), will exceed 0.10g in 250 years.

A review of USGS Miscellaneous Field Study Map MF-2120, "Probabilistic Earthquake Acceleration and Velocity Maps for the United States and Puerto Rico", (Algermissen, et. al., 1991), was conducted.

El Paso County (and the Landfill) fall outside of any designated seismic impact zones (See Figure 6).

7. UNSTABLE AREAS

7.1 REGULATORY REQUIREMENTS

Owners and operators of MSWLF units must demonstrate that proper engineering measures have been incorporated into the design in unstable areas. Those areas considered to be susceptible to natural or man-made events that may impair or destroy the integrity of any of the landfills structural components includes, but is not limited to:

- poor foundation conditions
- areas susceptible to mass movements (such as landslides, debris flows, etc.)
- Karst terranes

7.2 GEOLOGIC SETTING

The McCombs Landfill is located on deposits of the Hueco Bolson, probably Camp Rice Formation. These deposits primarily consist of clay, sand and gravel, with some caliche (Bureau of Economic Geology, 1983). The landfill site is underlain by Tertiary and Quaternary basin (bolson) deposits, overlain by areas of gravel and caliche rimrock (Harbour, 1972). Recent Quaternary alluvial deposits are also present in the landfill vicinity in topographically low areas.

The caliche rimrock of Pleistocene age is commonly two to four feet thick, and consists of angular fragments of bedrock derived from the mountains and cemented by white caliche. The bolson deposits in the area were described by Harbour (1972) as "friable white sand with rounded volcanic pebbles". Bolson deposits of clay and sand with some gravel and caliche have been observed in water wells drilled east of the Franklin Mountains. The bolson deposits have been documented to extend to a depth of at least 4,920 feet below ground surface in a well drilled south of Newman, New Mexico, approximately five miles east of the landfill (Harbour, 1972).

7.3 GEOTECHNICAL SETTING

A soil investigation was performed in 1983 by DRA. During the investigation, numerous soil borings were drilled on site to a depth of 60 feet below ground surface. According to boring logs generated during the investigation, the soils consist of an upper zone of variable thickness of silty sand, underlain by deposits of clean and gravelly sands. Stringers of clay which did not appear to be laterally extensive were observed in some of the soil borings. The sands and gravelly sands appear to be lenticular in nature, with little correlation across the site.

Based on the above information, it does not appear that any expansive or collapsible soils which would affect performance of the landfill have been identified.

7.4 UNSTABLE SLOPES

No landslide deposits in the vicinity of the Landfill are shown on any published geologic information and none have been identified during our site visits.

Since less than 40 feet of topographic relief occur across the site and no evidence of unstable slopes were observed, it is our opinion that no unstable slopes which would affect the structural integrity of the Landfill occur on site. Localized areas of loose soil could potentially produce unstable slopes in temporary excavations, but these can be mitigated by proper site grading.

7.5 KARST TERRANES

As noted above, several thousand feet of basin filling sediments occur beneath the Landfill. No limestone or other soluble units subject to karst formation exists in the vicinity.

7.6 SUBSIDENCE

Subsidence has been documented in the El Paso metropolitan area as a result of groundwater withdrawal and subsequent decline in groundwater levels, especially in areas having thick accumulations of clay in the subsurface.

The McCombs Landfill is located in an area of documented groundwater withdrawal resulting in groundwater declines up to 40 feet (Ashworth, 1990). No land surface subsidence has been documented in the vicinity of the Landfill (Land and Armstrong, 1985). Due to depth to groundwater, formation of large scale subsidence features is not anticipated, but cannot be precluded.

7.7 LIQUEFACTION

Since groundwater occurs at depths of over 400 feet (El Paso Water Utilities, 1993), no liquefaction concerns exist (SHB, 1993).

7.8 HUMAN-INDUCED INSTABILITIES

As part of the design of proposed additions to the McCombs Municipal Landfill, it is our understanding that a geotechnical engineering firm and a civil design team have been retained by the City. We assume these consultants are taking into account foundation conditions, slope stability and other sources in their design to minimize short-term or man-induced instabilities. This documentation has been submitted as part of the permit modification.

8. CONCLUSIONS

Based on our review of available information, the McCombs Municipal Landfill is not currently subject to any restrictions due to the presence of geologic hazards, airport safety concerns or from being within a 100-year floodplain. Fault restrictions may be a concern for future additions, however, no retrofitting of existing structures is required under current regulations.

Municipal Solid Waste (MSW) - Permit No. 729A
Monitor Well Installation Report
Tracking No. 14882536; CN601410244/RN100215599

Dear Ms. Smyth:

This letter acknowledges that we received a report documenting the installation of two piezometer monitor wells (PZ-4, PZ-5) at the referenced facility. The report was prepared by Parkhill, Smith & Cooper, Inc. (PSC) of El Paso, Texas and submitted on behalf of the facility by the supervising engineer Matt Dyer, P.E. of PSC, under a cover letter dated August 12, 2011. The report includes a well location map, geologic boring logs, well completion logs, monitor well data sheets, and State of Texas Well Reports for each well.

Thank you for the submittal. The installation appears to be in accordance with provisions of the permit modification issued on October 9, 2009.

If you have any questions in regard to this letter, please contact me at (512) 239-2242. When addressing written correspondence, please use mail code MC 124.

Sincerely,

Jason Wang, P.G.

1.0 INTRODUCTION

This report is submitted in accordance with 30 TAC §330.421 (e), and documents the construction of two piezometer wells, at the City of El Paso McCombs Landfill (MSW Permit No. 0729A) Changes to the groundwater monitoring system were submitted in two separate permit modification requests. The first request, approved in October 2009, updated the Groundwater Sampling and Analysis Plan and approved the installation of PZ-4 and PZ-5. The second request, approved December 2009, indicated that the facility would begin monitoring wells 1, 2, 3, and PZ-5 in accordance with the GWSAP as soon as PZ-5 is installed. Piezometer wells PZ-4 and PZ-5 have been installed to TCEQ groundwater monitoring well standards.

Actual construction of the wells was performed by WDC Exploration and Well of Peralta, New Mexico. Michael Hull, P.G. (Texas Registration No. 4152) witnessed the installation of the monitor and piezometer wells.

2.0 GROUNDWATER MONITOR WELL CONSTRUCTION

The piezometers were constructed using an Air Rotary Casing Hammer (ARCH) System, which consists of a non-rotating flush-threaded casing driven in conjunction with a conventional air rotary drill string. The advanced drive casing is a heavy walled pipe. The casing was driven with a pneumatic casing hammer. As the casing was advanced, the cuttings were cleared from the hole by rotation of the bit and air circulation. Cuttings were discharged though a hose into a cyclone, where they were separated from the air and contained for sample collection. Once the well was drilled to its total depth the drill rod and bit were extracted from the center of the drive casing and well casing was installed. After the casing was placed the annulus was filled as demonstrated in the design and permit documentation as the drive casing was pulled from the hole.

Well casing and screen was new 4-inch National Science Foundation certified Polyvinyl Chloride (PVC) Schedule 80 pipe. Screen pipe was slotted with 0.010-inch wide slots. The screened areas of the well were packed with Carmeuse Industrial Sands Colorado Spring Silica Sand 10/20 filter pack material. The annular seal above the gravel pack was made with a sodium

bentonite product (Holeplug) and the casing seal from the top of the annular seal to ground surface was made with a bentonite grout (Quik-Grout), both products manufactured by Baroid.

Following well construction, a concrete sealing block was constructed around the well for additional protection. Additionally, four 6-inch diameter steel bollards filled with concrete were placed around the well and painted with safety yellow paint for increased visibility and protection from vehicular traffic.

The well was then surveyed by Mr. Kenneth R. Kindle, a Texas Registered Professional Land Surveyor (RPLS 5710), and the well elevations were permanently mounted on each wells 8-inch diameter steel protective casing.

The construction specification for these wells is included for information in the Appendix.

3.0 WELL DEVELOPMENT

Following construction, each monitor well was developed using a small portable submersible stainless steel pump. The pump was placed at the bottom of the casing and pumped continuously for a minimum of between three and four hours. The water was relatively free of sand, and the temperature, specific conductivity and pH readings were constant at the end of the development period. A turbidity value of five (5) on the Jackson Turbidity Scale was used as a target well cleanliness value. The pumping rate varied between 5 and 5.3 gallons per minute during development. All equipment used in the development process was decontaminated between each well. The water produced during development was discharged onsite near the well.

4.0 MISCELLANEOUS DOCUMENTATION

The following items have been included in the Appendix to this report:

- State of Texas Well Report
- Monitor Well Data Sheet
- Geologic Boring Logs
- TCEQ Correspondence
- Material Information and MSDS Safety Sheets

- Construction Specifications
- Figure 1 – Vicinity Location Map
- Figure 2 – Monitor Well Layout Map
- Figure 3 – Typical Well Construction Details
- Figure 4 – Survey

5.0 CERTIFICATION OF GROUNDWATER MONITORING SYSTEM

In the professional opinion of R. Matt Dyer, P.E. as a registered professional engineer in the State of Texas (Registration No. 92189), the groundwater monitoring system was designed in accordance with TCEQ rules and regulations as published in 30 TAC §330, Subchapter J. To the best of my knowledge, no significant alterations were made by the contractor during actual construction of the piezometers.

Sincerely,

PARKHILL, SMITH & COOPER, INC.

By R Matt Dyer

NOTES:

- Report all depths from Surface Elevation and all Elevations relative to Mean Sea Level (MSL), to nearest hundredth of a foot.
- Diameter of boring should be at least 4 inches larger than diameter of well casing.
- Use flush screw joint casing only, 2-inch diameter or larger, with o-rings or PTFE tape in joints (4-inch diameter recommend).
- Well development should continue until water is clear, and pH and conductivity are stable.

Geologist, Hydrologist, or Engineer Supervising Well Installation: Michael J. Hull, PG
Static Water Level Elevation (with respect to MSL) after Well Development: 3,650.81' MSL
Name of Geologic Formation(s) in which Well is completed: Hueco Bolson

PIEZOMETER WELL 5 (PZ-5)

State of Texas Well Report
Monitor Well Data Sheet
Boring Log

STATE OF TEXAS WELL REPORT for Tracking #256218

Owner:	**City of El Paso Environmental Services D**	Owner Well #:	**PZ-5**
Address:	**7968 San Paulo El Paso , TX 79907**	Grid #:	**49-05-3**
Well Location:	**13600 McCombs St. El Paso , TX 79934**	Latitude:	**31° 59' 29" N**
Well County:	**El Paso**	Longitude:	**106° 23' 54" W**
Elevation:	**4058 ft.**	GPS Brand Used:	**Samsung Epic**
Type of Work:	**New Well**	Proposed Use:	**Monitor**

Drilling Date: Started: **5/23/2011**
Completed: **5/25/2011**

Diameter of Hole: Diameter: **10 in From Surface To 441 ft**

Drilling Method: **Air Rotary** Other: **Casing Hammer**

Borehole Completion: Gravel Packed From: **413 ft to 441 ft**
Gravel Pack Size: **10/20 Sand**

Annular Seal Data: 1st Interval: **From 3 ft to 403 ft with 40/ Bent. Grout (#sacks and material)**
2nd Interval: **From 403 ft to 413 ft with 5/ Bent. Chips (#sacks and material)**
3rd Interval: **No Data**
Method Used: **Tremie**
Cemented By: **WDC**
Distance to Septic Field or other Concentrated Contamination: **No Data**
Distance to Property Line: **No Data**
Method of Verification: **No Data**
Approved by Variance: **No Data**

Surface Completion: **Surface Sleeve Installed**

Water Level: Static level: **No Data**
Artesian flow: **No Data**

Packers: **No Data**

Plugging Info: Casing or Cement/Bentonite left in well: **No Data**

Type Of Pump: **No Data**

Well Tests: **No Data**

Water Quality: Type of Water: **No Data**
Depth of Strata: **No Data**
Chemical Analysis Made: **No**
Did the driller knowingly penetrate any strata which contained undesirable constituents: **No**

Certification Data: The driller certified that the driller drilled this well (or the well was drilled under the driller's direct supervision) and that each and all of the statements herein are true and correct. The driller understood that failure to complete the required items will result in the log(s) being returned for completion and resubmittal.

Company Information: **WDC Exploration and Wells**
3621 Hwy 47

	Peralta , NM 87042
Driller License Number:	**4885**
Licensed Well Driller Signature:	**William B. Bludworth**
Registered Driller Apprentice Signature:	**No Data**
Apprentice Registration Number:	**No Data**
Comments:	**No Data**

IMPORTANT NOTICE FOR PERSONS HAVING WELLS DRILLED CONCERNING CONFIDENTIALITY

TEX. OCC. CODE Title 12, Chapter 1901.251, authorizes the owner (owner or the person for whom the well was drilled) to keep information in Well Reports confidential. The Department shall hold the contents of the well log confidential and not a matter of public record if it receives, by certified mail, a written request to do so from the owner.

Please include the report's Tracking number (Tracking **#256218**) on your written request.

DESC. & COLOR OF FORMATION MATERIAL

From (ft) To (ft) Description
0- 43 Sand and Gravel, light red brown, vf to gravel.
43- 46 Silty Clay, lt brown.
46- 60 Sand and Gravel, lt red brown, fine to coarse gravel.
60- 61 Gravel, brown, pea size to cobbles.
61- 68 Clay, lt red brown.
68- 69 Sand, lt red brown, fine to coarse.
69- 72 Clay, lt red brown, some sand and silt.
72- 73 Sand, lt brown, fine to coarse.
73- 76 Silty Clay, lt gray brown.
76- 79 Sand, lt brown, fine to medium.
79- 90 Clay, red brown.
90-110 Sand, lt gray brown, silt to fine, dry.
110-138 Sand and Gravel, lt brown to lt gray, fine to coarse, dry.
138-141 Clay, brown and red brown.
141-160 Sand and Gravel, lt gray to lt gray brown, fine, some gravel, dry.
160-177 Silty Sand, lt gray brown, dry.
177-189 Silty Sand and Gravel, red brown, dry.
189-196 Clay, red brown, dry.
196-210 Sand, red brown, fine to medium, sl damp.
210-220 Sand, lt gray brown, fine to medium, dry.
220-223 Sand, lt gray, fine to medium.
223-230 Sandy Gravel, lt gray brown.
230-260 Sand, lt gray brown, fine to medium.

CASING, BLANK PIPE & WELL SCREEN DATA

Dia. New/Used Type Setting From/To
4 N PVC Riser +3-418 Sch#80
4 N PVC Slotted Screen 418-438 .010"
4 N PVC Sump 438-440 Sch#80

260-280 Sand, as above, but vf.
280-300 Sand, lt brown, silt to medium.
300-310 Sand and Gravel, lt brown, sl damp.
310-313 Sand, red brown, silty to vf.
313-323 Sandy Silt, lt brown.
323-327 Gravel and Sand, lt gray brown.
327-332 Sand and Gravel, light gray brown.
332-335 Clay, red brown.
335-340 Silty Sand, red brown.
340-343 Sand and Gravel, light brown, fine to pea gravel.
343-369 Clay, red brown.
369-384 Sand, light red brown, very fine to coarse.
384-385 Silty Clay, red brown, moist.
385-387 Clay, red brown, dry, hard.
387-396 Sand, red brown, fine.
396-400 Clay, red brown, slightly moist.
400-402 Sand, red brown, fine, dry.
402-403 Clay, red brown, moist.
403-410 Sand, red brown, fine, moist.
410-420 Sand, brown, fine, wet.
420-429 Sand, light brown to brown, fine to coarse, wet.
429-435 Sand, brown, fine.
435-439 Sand and Gravel, brown.
439-441 Clay, red brown.

Monitor Well Data Sheet

Permittee or Site Name: McCombs Landfill
County: El Paso County
Date of Monitor Well Installation: May 25, 2011
Latitude: 31°59'29.26715" Longitude: 106°23'53.84750"
Monitor Well Groundwater Gradient Position:
Upgradient: _____ Downgradient: _____

MSW Permit No.: 729A
Monitor Well I.D. No.: PZ-5
Date of Monitor Well Development: June 7, 2011
Monitor Well Driller
Name: William B. Bludworth
License No. 4885

NOTES:

- Report all depths from Surface Elevation and all Elevations relative to Mean Sea Level (MSL), to nearest hundredth of a foot.
- Diameter of boring should be at least 4 inches larger than diameter of well casing.
- Use flush screw joint casing only, 2-inch diameter or larger, with o-rings or PTFE tape in joints (4-inch diameter recommend).
- Well development should continue until water is clear, and pH and conductivity are stable.

Geologist, Hydrologist, or Engineer Supervising Well Installation: Michael J. Hull, PG
Static Water Level Elevation (with respect to MSL) after Well Development: 3,653.97' MSL
Name of Geologic Formation(s) in which Well is completed: Hueco Bolson

Type of Locking Device: Pad Lock Type of Casing Protection: 6" x 6" x 5' Steel
Concrete Surface Pad (with steel reinforcement) Dimensions: 4' x 4' x 6"

Municipal Solid Waste – Permit No. 729A
Permit Modification – Groundwater Monitoring System – Status Update
Tracking No. 12963070; RN100215599 / CN601410244

Dear Ms. Smyth:

This letter acknowledges that we received a response to our letter dated December 14, 2009, regarding your application for a municipal solid waste permit modification dated January 2, 2008 (and revisions), proposing changes to the Site Characterization and Monitoring Plan for the referenced facility. The response indicated that the facility would begin monitoring in accordance with the facility Groundwater Sampling and Analysis Plan in existing monitor wells MW-1, 2, and 3, and in piezometer PZ-5 at the first event following the installation of PZ-5, as requested in our letter.

Thank you for the response. We will look forward to receiving groundwater monitoring results later this year as indicated in the response letter, as well as the results of the additional groundwater investigation that is to take place this year, and following that a completed monitoring system design.

If you have questions regarding this letter, please contact me at (512) 239-4419. When addressing written correspondence, please use mail code MC 124.

Sincerely,

Arten J. Avakian, P.G., Project Manager

Re: City of El Paso McCombs Municipal Landfill – El Paso County
Municipal Solid Waste – Permit No. 729A
Permit Modification – Groundwater Monitoring System – Notice of Deficiency
Tracking No. 12904919; RN100215599 / CN601410244

Dear Ms. Smyth:

We have reviewed your application for a municipal solid waste permit modification dated January 2, 2008, and the revisions dated July 6, 2009, September 10, 2009, and November 6, 2009, proposing changes to the Site Characterization and Monitoring Plan for the referenced facility. The purpose of the changes is to address the revised groundwater monitoring and corrective action requirements in Title 30 Texas Administrative Code (30 TAC), Chapter 330, Subchapter J that became effective March 27, 2006 (2006 Revisions). The most recent revisions were submitted in response to comments in our letter dated October 8, 2009.

Thank you for the submittal. In our letter dated October 8, 2009, we advised that you may proceed with your plan to install two piezometers (PZ-4 and PZ-5) and conduct additional groundwater investigations for one year, and to submit a completed monitoring system design after the investigation. We also commented that during the interim you should begin groundwater monitoring in existing monitor wells MW-1, MW-2, and MW-3, and in piezometers PZ-4 and PZ-5 in accordance with the recently modified Groundwater Sampling and Analysis Plan (GWSAP) for the facility. The response to that comment requested that monitoring of the piezometers be delayed until after the additional investigation is complete and the hydraulic position of the piezometers is confirmed. According to information in the application, the location for PZ-4 may be upgradient of waste cells (instead of downgradient as indicated in the existing permit); however, it appears the location proposed for PZ-5 is downgradient from waste cells based on information in the existing permit and in the application. In addition, the location for PZ-5 may be on a groundwater flow path that leads back to existing landfill cells where waste has already been placed. It seems justifiable to delay sampling of PZ-4 (which may be upgradient), but not PZ-5.

We therefore are modifying the request in our letter dated October 8, 2009, and ask that you begin monitoring in accordance with the facility GWSAP in existing monitor wells MW-1, 2, and 3, and in piezometer PZ-5 at the first event following the installation of PZ-5.

Please respond within 30 days from the date of this letter. As a reminder, when you later revise your application, please ensure that each page has a header or footer that indicates the revision number and date, in accordance with 30 TAC §330.57. The revised and/or additional pages should be in a form suitable for replacement and/or inclusion in the initial permit modification application. In accordance with 30 TAC §305.44, please include an original certification statement with the revision. Along with the original signature and date, the certification statement should indicate the name, title, and address of the responsible official.

Also, when you submit the next revision, please provide one original, two unmarked copies, and one marked copy (for example, in redline/strikeout format) of the revisions in accordance with 30 TAC §305.70(f), to facilitate our review. Please send one of the unmarked copies directly to TCEQ Region 6, to the attention of Mr. Kent Waggoner, Waste Section Manager, 401 East Franklin Avenue, Suite 560, El Paso, Texas 79901-1212. Also, please include the tracking number referenced above in the subject line of your response. Note that we may have additional comments after we review the revised application.

If you have questions regarding this letter, please contact me at (512) 239-4419. When addressing written correspondence, please use mail code MC 124.

Sincerely,

Re: McCombs Landfill – El Paso County
Municipal Solid Waste - Permit No. 729A
Permit Modification – Groundwater Sampling and Analysis Plan (GWSAP)
Tracking Nos. 11969813 and 12831440; RN100215599/CN601410244

Dear Ms. Smyth:

We have reviewed your application for a municipal solid waste permit modification dated January 2, 2008, and the revision received September 11, 2009 requesting changes to the GWSAP for the referenced facility. The purpose of the requested changes is to address the revised groundwater monitoring and corrective action requirements in Title 30 Texas Administrative Code, Chapter 330, Subchapter J that became effective March 27, 2006 (2006 Revisions). The information presented is technically sufficient for a municipal solid waste permit modification.

Enclosed is a copy of the above referenced modification which is now part of your permit and should be attached thereto. The documentation prepared and submitted to support the modification request shall be considered as requirements of the permit.

If you have questions concerning this matter, please contact Ms. Eleanore Whitworth at (512) 239-2347. When addressing written correspondence, please use mail code MC 124.

This action is taken under authority delegated by the Executive Director of the Texas Commission on Environmental Quality.

Sincerely,

Richard C. Carmichael, Ph.D., P.E.
Manager, Municipal Solid Waste Permits Section
Waste Permits Division

Enclosure

TEXAS COMMISSION ON ENVIRONMENTAL QUALITY

MODIFICATION TO

MUNICIPAL SOLID WASTE PERMIT NO. 729A

CITY OF EL PASO MCCOMBS LANDFILL

Municipal Solid Waste Permit No. 729A is hereby modified as follows:

Description of Change:

Authorizes changes to the Groundwater Sampling and Analysis Plan to address the revised groundwater monitoring and corrective action requirements of Title 30 Texas Administrative Code, Chapter 330, Subchapter J that became effective March 27, 2006, (2006 Revisions).

The details of this permit modification are contained in the application dated January 2, 2009, and the revision dated September 10, 2009.

Part of Permit Modified:

Site Development Plan

Attachment 11, Groundwater Sampling and Analysis Plan

This modification is a part of Permit No. 729A and should be attached thereto.

APPROVED, ISSUED, AND EFFECTIVE in accordance with Title 30 Texas Administrative Code, Chapter 305, Section 305.70(j)(23) and Chapter 330, Subchapter J.

ISSUED DATE:

OCT 09 2009

For the Commission

Revision No. 3

Material Safety Data Sheet

Product Name:	**SAND**

INFOTRAC: 800-535-5053 [In case of an emergency call this number 24 HOURS a day 7 DAYS a week.]

SECTION 1 - IDENTIFICATION OF THE SUBSTANCE AND COMPANY

1.1. Identification of the substance:

Chemical name:	Silica
Product name & synonyms:	Silica Sand, Colorado Silica Sand ®, Glass Sand, Flint, Sand, Silica Sand, Quartz, Crystalline Silica, Flint, Ground Silica, Foundry Sand, Engine Sand, Frac Sand, Filtration Sand, Bunker Sand, Turf Sand, Glass Sand, Silica Flour, Natural alluvial sand and gravel, ¾, $^5/_8$, ½, ¼, #4, #6, #12, #16, #20, #30, #60, #80, 4x50, Root Zone, Top Dressing, Bunker Sand, Play Sand, Masonry, Plaster Sand, $^1/_{8th}$ washed, .45-.55, Davis, or blends.
Formula:	SiO_2
Material Uses:	Industries such as gas & oil, water filtration, construction materials, cement, non-skid surfaces, fillers, golf course sand, artificial athletic sands and insecticides

1.2. Company:

Main Office:
11 Stanwix Street, 11th Floor
Pittsburgh, PA 15222
Telephone: 412-995-5500
Fax: 412-995-5594

Canadian Office:
P.O. Box 190
Ingersoll, Ontario N5C 3K5
Telephone: 519-423-6283
Fax: 519-423-6545

SECTION 2 - COMPOSITION / INFORMATION ON INGREDIENTS

Ingredient	% by Weight	CAS #	Exposure Limits
Crystalline silica quartz	90.0 – 99.9	14808-60-7	OSHA PEL: 30 mg/m³ / (% silica + 2) (total) 10 mg/m³ / (% silica + 2) (respirable) ACGIH TLV: 0.025 mg/m³ (respirable)

This material is classified as hazardous under OSHA regulations.

WARNING: Never Use This Material for Sand Blasting

Product Name:	SAND (continued)

SECTION 3 – HAZARDS IDENTIFICATION

EMERGENCY OVERVIEW: A white or tan sand, or ground sand. It is not flammable, combustible or explosive. Do not breathe this material. Crystalline silica (quartz) is not known to be an environmental hazard. Crystalline silica (quartz) is incompatible with hydrofluoric acid, fluorine, chlorine trifluoride or oxygen difluoride.

POTENTIAL HEALTH EFFECTS

EYE Contact can cause moderate to severe irritation of eyes, including discomfort or pain, local redness and swelling of the conjuctiva.

SKIN Contact can cause dryness or moderate irritation of skin.

INGESTION None known.

INHALATION If inhaled as dust, this product can cause irritation of the respiratory system resulting in coughing and/or sneezing. Higher exposures may cause a build-up of fluid in the lungs with severe shortness of breath. Inhalation of silica can also cause a chronic irreversible lung disorder, silicosis. Some medical reports state inhalation of silica dust may cause lung cancer.

Per ACGIH, adverse effects are not likely to occur in the workplace provided exposure levels do not exceed the appropriate TLVs/PELs. See Section 8. However, because of the wide variation in individual susceptibility, lower exposure limits may be appropriate for some individuals including persons with pre-existing medical conditions.

CHRONIC EFFECTS / CARCINOGENICITY: Silicosis, cancer, scleroderma, tuberculosis, nephrotoxicity and arthritis are potential chronic effects. See Section 11 for further information regarding these conditions

SIGNS AND SYMPTOMS OF EXPOSURE: There are generally no signs or symptoms of exposure to crystalline silica (quartz). Often, chronic silicosis has no symptoms. The symptoms of chronic silicosis, if present, are shortness of breath, wheezing, cough and sputum production. The symptoms of acute silicosis are the same; additionally, weight loss and fever are associated with acute silicosis. The symptoms of scleroderma include thickening and stiffness of the skin, particularly in the fingers, shortness of breath, difficulty swallowing and joint problems.

MEDICAL CONDITIONS GENERALLY AGGRAVATED BY EXPOSURE: The condition of individuals with lung disease (e.g., bronchitis, emphysema, chronic obstructive pulmonary disease) can be aggravated by exposure. See Section 11 for additional detail on potential adverse health effects.

POTENTIAL ENVIRONMENTAL EFFECTS: None known.

SECTION 4 – FIRST AID MEASURES

EYE Quickly and gently blot or brush away sand. Immediately flush the contaminated eye(s) with lukewarm, gently flowing water for at least 15 minutes or until the sand is removed, while holding the eyelid(s) open. Occasionally lift eyelid(s) to ensure thorough rinsing. Beyond flushing, do not attempt to remove material from eye(s). Do not rub eyes. Seek medical attention immediately.

SKIN Wash with soap and water. Seek medical attention if irritation persists.

INGESTION Never give anything by mouth if the victim is rapidly losing consciousness, or is unconscious or convulsing. Have victim rinse mouth thoroughly with water. If irritation or discomfort occurs, obtain medical advice immediately.

INHALATION Remove source of contamination or move victim to fresh air. Seek medical attention if necessary. If breathing has stopped, give artificial respiration.

Product Name:	SAND (continued)

SECTION 5 – FIRE FIGHTING MEASURES

Flammable Properties

Flash Point: Not flammable Method: N/A

EXTINGUISHING MEDIA	None required. Use suitable extinguishing media for surrounding fire.
FIRE & EXPLOSION HAZARDS	None
FIRE FIGHTING INSTRUCTIONS	None

SECTION 6 – ACCIDENTAL RELEASE MEASURES

SPILL /LEAK PROCEDURES — Use dustless methods (vacuum) and place in closable container for disposal or flush with water. Do not dry sweep. Use proper protective equipment indicated in Section 8.

SECTION 7 – HANDLING AND STORAGE

HANDLING — Keep in tightly closed containers. Protect containers from physical damage. Avoid direct skin contact with the material.

Silica sand material contains fine dust. If you breathe this dust you can suffer severe, irreversible lung damage and death. Some medical reports state inhalation of silica dust may cause lung cancer. Medical reports also link breathing silica dust to crippling arthritis and skin and eye irritation. See Section 11 for further information.

You must never use this material without having a government-approved respirator. The work area must also be thoroughly ventilated by the use of forced air ventilation during and after use of this material.

If dusty, use protective goggles. An eye wash station should be readily available where this product is used.

Prior to use or handling, you are advised to review and thoroughly understand all health precautions outlined in the Material Safety Data Sheet (MSDS).

STORAGE — Store in a cool, dry, and well-ventilated location. Do not store near incompatible materials. (See Section 10 for list of incompatible materials.) Avoid breakage of bagged materials or spills of bulk material.

Product Name:	SAND (continued)

SECTION 8 – EXPOSURE CONTROLS / PERSONAL PROTECTION

ENGINEERING CONTROLS

Use sufficient local exhaust to reduce the level of respirable crystalline silica to below the PEL. See ACGIH "Industrial Ventilation, A Manual of Recommended Practice" (latest edition).

RESPIRATORY PROTECTION

Use NIOSH/MSHA approved respirators if airborne concentration exceeds PEL. It is a violation of federal safety laws (OSHA) for employers to require workers to use this material without full respiratory protection. The federal laws that apply are: 29CFR 1910.134; 29CFR 1910.1000; 29CFR 1910.94.

The following chart specifies the types of respirators that may provide respiratory protection for crystalline silica.

Particulate Concentration	MINIMUM RESPIRATORY PROTECTION*
10 x PEL or less	Any particulate respirator, except single -use or quarter-mask respirator. Any fume respirator or high efficiency particulate filter respirator. Any supplied-air respirator. Any self-contained breathing apparatus.
50 x PEL or less	A high efficiency particulate filter respirator with a full facepiece. Any supplied-air respirator with a full facepiece, helmet, or hood. Any self-contained breathing apparatus with a full facepiece.
500 x PEL or less	A powered air-purifying respirator with a high efficiency particulate filter. A Type C supplied-air respirator operated in pressure-demand or other positive pressure or continuous-flow mode.
Greater than 500 x PEL or entry and escape from unknown concentrations	A type C, supplied-air respirator with a full facepiece, hood, or helmet, operated in a positive pressure mode (see 29 CFR 1910.94(a)(iii)). Also see 30 CFR Part 11.

*Use only NIOSH-approved or MSHA-approved equipment. See 29 CFR §1910.134 and 42 CFR §84.

See also ANSI standard Z88.2 (latest revision) "American National Standard for Respiratory Protection"

SKIN PROTECTION

Use appropriate gloves to prevent skin contact. Clothing should fully cover arms and legs and be tight fitting at the cuffs, neck and ankles to prevent dust from contacting the body. Clothing should be regularly washed to prevent dust accumulation.

EYE PROTECTION

Use safety goggles.

EXPOSURE GUIDELINES	OSHA PEL	ACGIH TLV
Crystalline silica (respirable)	10 mg/m^3 ÷ (% silica in the dust plus 2)	0.025 mg/m^3

Crystalline silica exists in several forms, the most common of which is quartz. If crystalline silica (quartz) is heated to more than 870°C it can change to a form of crystalline silica known as trydimite, and if crystalline silica (quartz) is heated to more than 1470°C, it can change to a form of crystalline silica known as cristobalite. Crystalline silica as trydimite and cristobalite are more fibrogenic than crystalline silica as quartz. The OSHA PEL for crystalline silica as trydimite and cristobalite is one-half the PEL for crystalline silica (quartz); the ACGIH TLV for crystalline silica as trydimite and cristobalite is one-half the TLV for crystalline silica as quartz.

Product Name:	SAND (continued)

SECTION 9 – PHYSICAL AND CHEMICAL PROPERTIES

APPEARANCE	White or tan sand; granular, crushed, or ground
ODOR	Odorless
BOILING POINT	4046°F
MELTING POINT	3110°F
VAPOR PRESSURE	N/A
SOLUBILITY IN WATER	Insoluble
SPECIFIC GRAVITY	2.65
pH	N/Ap

SECTION 10 – STABILITY AND REACTIVITY

STABILITY	Chemically stable.
MATERIALS TO AVOID	Contact with powerful oxidizing agents such as fluorine, boron trifluoride, chlorine trifluoride, manganese trifluoride, oxygen difluoride, may cause fires and/or explosions.
CONDITIONS TO AVOID	None
HAZARDOUS DECOMPOSITION PRODUCTS	Silica will dissolve in hydrofluoric acid and produce a corrosive gas – silicon tetrafluoride.

SECTION 11 – TOXICOLOGICAL INFORMATION

No LD_{50} or LC_{50} have been identified for this product.

SILICOSIS

The major concern is silicosis, caused by the inhalation and retention of respirable crystalline silica dust. Silicosis can exist in several forms, chronic (or ordinary), accelerated, or acute.

Chronic or Ordinary Silicosis is the most common form of silicosis, and can occur after many years of exposure to relatively low levels of airborne respirable crystalline silica dust. It is further defined as either simple or complicated silicosis.

> Simple silicosis is characterized by lung lesions (shown as radiographic opacities) less than 1 centimeter in diameter, primarily in the upper lung zones. Often, simple silicosis is not associated with symptoms, detectable changes in lung function or disability. Simple silicosis may be progressive and may develop into complicated silicosis or progressive massive fibrosis (PMF).
>
> Complicated silicosis or PMF is characterized by lung lesions (shown as radiographic opacities) greater than 1 centimeter in diameter. Although there may be no symptoms associated with complicated silicosis or PMF, the symptoms, if present, are shortness of breath, wheezing, cough and sputum production. Complicated silicosis or PMF may be associated with decreased lung function and may be disabling. Advanced complicated silicosis or PMF may lead to death. Advanced complicated silicosis or PMF can result in heart disease secondary to the lung disease (cor pumonale).

Accelerated Silicosis can occur with exposure to high concentrations of respirable crystalline silica over a relatively short period; the lung lesions can appear within five (5) years of the initial exposure. The progression can be rapid. Accelerated silicosis is similar to chronic or ordinary silicosis, except that the lung lesions appear earlier and the progression is more rapid.

Acute Silicosis can occur with exposures to very high concentrations of respirable crystalline silica over a very short time period, sometimes as short as a few months. The symptoms of acute silicosis include progressive shortness of breath, fever, cough and weight loss. Acute silicosis is fatal.

CANCER

IARC - The International Agency for Research on Cancer ("IARC") concluded that there was "*sufficient evidence* in humans for the carcinogenicity of crystalline silica in the forms of quartz or cristobalite from occupational sources", and that there is "*sufficient evidence* in experimental animals for the carcinogenicity of quartz and cristobalite." The overall IARC evaluation was that "crystalline silica inhaled in the form of quartz or cristobalite from occupational sources is *carcinogenic to humans*

(Group 1)." The IARC evaluation noted that "carcinogenicity was not detected in all industrial circumstances studies. Carcinogenicity may be dependent on inherent characteristics of the crystalline silica or on external factors affecting its biological activity or distribution of its polymorphs." For further information on the IARC evaluation, see IARC Monographs on the Evaluation of Carcinogenic Risks to Humans, Volume 68, "Silica, Some Silicates..." (1997). (Emphasis added)

NTP - The National Toxicology Program, in its Sixth Annual Report on Carcinogens, concluded that "silica, crystalline (respirable)" may reasonably be anticipated to be a carcinogen, based on sufficient evidence in experimental animals and limited evidence in humans.

OSHA - Crystalline silica (quartz) is not regulated by the U. S. Occupational Safety and Health Administration as a carcinogen.

There is substantial literature on the issues of the carcinogenicity of crystalline silica, which the reader should consult for additional information. A summary of the literature is set forth in "Exposure to crystalline silica and risk of lung cancer; the epidemiological evidence", Thorax, Volume 51, pp. 97-102 (1996). The official statement of the American Thoracic Society on the issue of silica carcinogenicity was published in "Adverse Effects of Crystalline Silica Exposure", American Journal of Respiratory and Critical Care Medicine, Volume 155, pp. 761-765 (1997). The official statement concluded that "The available data support the conclusion that silicosis produces increased risk for bronchogenic carcinoma. The cancer risk may also be increased by smoking and other carcinogens in the workplace. Epidemiologic studies provide convincing evidence for increased cancer risk among tobacco smokers with silicosis. Less information is available for never-smokers and for workers exposed to silica but who do not have silicosis. For workers with silicosis, the risks for lung cancer are relatively high and consistent among various countries and investigators. Silicosis should be considered a condition that predisposes workers to an increased risk of lung cancer." Id. at 763.

SCLERODERMA

There is evidence that exposure to respirable crystalline silica or that the disease silicosis is associated with the increased incidence of scleroderma, an immune system disorder manifested by a fibrosis (scarring) of the lungs, skin and other internal organs. Recently, the American Thoracic Society noted that "there is persuasive evidence relating scleroderma to occupational silica exposures in setting where there is appreciable silicosis risk." The following may be consulted for additional information on silica, silicosis and scleroderma (also known as progressive systemic sclerosis): Occupational Lung Disorders, Third Edition, Chapter 12, entitled "Silicosis and Related Diseases", Parkes, W. Raymond (1994). "Adverse Effects of Crystalline Silica Exposure", American Journal of Respiratory and Critical Care Medicine, Volume 155, pp. 761-765 (1997).

TUBERCULOSIS

Individuals with silicosis are at increased risk to develop tuberculosis, if exposed to persons with tuberculosis. The following may be consulted for further information: Occupational Lung Disorders, Third Edition, Chapter 12, entitled "Silicosis and Related Diseases", Parkes, W. Raymond (1994). "Adverse Effects of Crystalline Silica Exposure", American Journal of Respiratory and Critical Care Medicine, Volume 155, pp. 761-765 (1997). Silica Sand (Brady, Colorado Springs, Riverside, Bakersfield)

NEPHROTOXICITY

There are several recent studies suggesting that exposure to respirable crystalline silica or that the disease silicosis is associated with the increased incidence of kidney disorders. The following may be consulted for additional information on silica, silicosis and nephrotoxicity: Occupational Lung Disorders, Third Edition, Chapter 12, entitled "Silicosis and Related Diseases", Parkes, W. Raymond (1994). "Further evidence of human silica nephrotoxicity in occupationally exposed workers", British Journal of Industrial Medicine, Vol. 50, No. 10, pp. 907-912 (1993). "Adverse Effects of Crystalline Silica Exposure", American Journal of Respiratory and Critical Care Medicine, Volume 155, pp. 761-765 (1997).

ARTHRITIS

There are recent studies suggesting that exposure to respirable crystalline silica or that the disease silicosis is associated with the increased incidence of arthritis. The following may be consulted for additional information on silica exposure and arthritis: American Journal of Industrial Medicine, Volume 35, pp. 375-381 "Connective Tissue Disease and Silicosis", Rosenman KD; Moore-Fuller M.; Reilly MJ. (1999). Environmental Health Perspective, Volume 107, pp. 793-802 "Occupational Exposure to Crystalline Silica and Autoimmune Disease", Parks CG; Conrad K; Cooper GS. (1999).

Product Name:	SAND (continued)

SECTION 12 – ECOLOGICAL INFORMATION

ECOTOXICITY: Crystalline silica (quartz) is not known to be ecotoxic; i.e., no data suggests that crystalline silica (quartz) is toxic to birds, fish, invertebrates, microorganisms or plants.

ENVIRONMENTAL FATE: This material shows no bioaccumulation effect or food chain concentration toxicity.

SECTION 13 – DISPOSAL CONSIDERATIONS

Dispose of in accordance with all applicable federal, state, and local environmental regulations. The material may be landfilled; however, used material may contain materials derived from other sources that because of contamination may not be disposed of in landfills. Disposed material should be covered to minimize generation of airborne dust.

RCRA: Crystalline silica (quartz) is not classified as a hazardous waste under the Resource Conservation and Recovery Act, or its regulations, 40 CFR §261 et seq. However, the material may be contaminated during use, and it is the responsibility of the user to assess the appropriate disposal of the used material.

SECTION 14 – TRANSPORT INFORMATION

US DOT	Not regulated
Proper Shipping Name	NA
Class	NA
UN Number	NA
Packing Group	NA

SECTION 15 – REGULATORY INFORMATION

EPA

RCRA Hazardous Waste Number: not listed (40 CFR 261.33)
RCRA Hazardous Waste Classification (40 CFR 261): not classified
CERCLA Hazardous Substance (40 CFR 302.4) unlisted specific per RCRA, Sec. 3001; CWA, Sec. 311(b)(4); CWA, Sec. 307(a), CAA, Sec. 112
CERCLA Reportable Quantity (RQ): not listed.
SARA 311/312 Codes: not listed.
SARA Toxic Chemical (40 CFR 372.65): not listed.
SARA EHS (Extremely Hazardous Substance) (40 CFR 355): Not listed, Threshold Planning Quantity (TPQ): not listed.
TSCA: All chemical ingredients are listed on the U.S. TSCA Inventory List.
FDA: Silica is included in the list of substances that may be included in coatings used in food contact surfaces, 21 CFR §175.300(b)(3)(xxvi).
California Proposition 65: Respirable crystalline silica (quartz) is classified as a substance known to the state of California to be a carcinogen.

OSHA/MSHA Regulations

Air contaminant (29 CFR 1910.1000, Table Z-1, Z-1-A): 5 mg/m^3 TWA-8
MSHA: not listed.
OSHA Specifically Regulated Substance (29CFR 1910): not listed.

Colorado Silica Sand® Meets AWWA-A100 and B100 standards; NSF-61 certification

CONTAINS FREE (RESPIRABLE) SILICA
DO NOT BREATHE DUST FROM THIS PRODUCT
NEVER USE FOR SAND BLASTING

This material contains fine (respirable) silica dust. If you inhale dust from this product you may develop silicosis, a severe, irreversible lung disease that can cause death. The National Institute for Occupational Safety and Health (NIOSH), the International Agency for Research on Cancer (IRAC) and the American Thoracic Society (ATS) link inhalation of silica dust to lung cancer. Medical reports link inhalation of silica dust to crippling arthritis. Exposure may cause skin and eye irritation.

NEVER USE THIS MATERIAL WITHOUT APPROVED RESPIRATORY PROTECTIVE EQUIPMENT

For approved respiratory protection equipment, refer to the National Institute for Occupational Safety and Health (NIOSH), the Occupational Safety and Health Act (OSHA) and the Mine Safety and Health Act (MSHA). See applicable Federal Laws:

29 C.F.R.§1910.134;29 C.F.R. §1910.1000 and 29 C.F.R. §1910.1000.

The technical data contained herein is subject to change without notice and does not represent a commitment on the part of Carmeuse Industrial Sands or its representatives. Over time and even within the same shipment, product gradations as well as physical and chemical characteristics may fluctuate due to natural variations in the raw product. It is recommended that the user request current technical data before making any design decisions.

HALLIBURTON

MATERIAL SAFETY DATA SHEET

Product Trade Name: **HOLEPLUG® 3/8**

Revision Date: 04-Jan-2011

1. CHEMICAL PRODUCT AND COMPANY IDENTIFICATION

Product Trade Name: HOLEPLUG® 3/8
Synonyms: None
Chemical Family: Mineral
Application: Fluid Loss Additive

Manufacturer/Supplier

Telephone: 1-580-251-4335
e-mail: fdunexchem@halliburton.com

2. COMPOSITION/INFORMATION ON INGREDIENTS

Substances	CAS Number	PERCENT	ACGIH TLV-TWA	OSHA PEL-TWA
Bentonite	1302-78-9	60 - 100%	Not applicable	Not applicable
Crystalline silica, tridymite	15468-32-3	0 - 1%	0.05 mg/m^3	$\frac{1/2 \times 10 \text{ mg/m}^3}{\%SiO2 + 2}$
Crystalline silica, cristobalite	14464-46-1	0 - 1%	0.025 mg/m^3	$\frac{1/2 \times 10 \text{ mg/m}^3}{\%SiO2 + 2}$
Crystalline silica, quartz	14808-60-7	0 - 5%	0.025 mg/m^3	$\frac{10 \text{ mg/m}^3}{\%SiO2 + 2}$

More restrictive exposure limits may be enforced by some states, agencies, or other authorities.

3. HAZARDS IDENTIFICATION

Hazard Overview

CAUTION! - ACUTE HEALTH HAZARD
May cause eye and respiratory irritation.

DANGER! - CHRONIC HEALTH HAZARD
Breathing crystalline silica can cause lung disease, including silicosis and lung cancer. Crystalline silica has also been associated with scleroderma and kidney disease.

This product contains quartz, cristobalite, and/or tridymite which may become airborne without a visible cloud. Avoid breathing dust. Avoid creating dusty conditions. Use only with adequate ventilation to keep exposures below recommended exposure limits. Wear a NIOSH certified, European Standard EN 149, or equivalent respirator when using this product. Review the Material Safety Data Sheet (MSDS) for this product, which has been provided to your employer.

4. FIRST AID MEASURES

Inhalation — If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Skin — Wash with soap and water. Get medical attention if irritation persists.

Eyes — In case of contact, immediately flush eyes with plenty of water for at least 15 minutes and get medical attention if irritation persists.

Ingestion — Under normal conditions, first aid procedures are not required.

Notes to Physician — Treat symptomatically.

5. FIRE FIGHTING MEASURES

Flash Point/Range (F):	Not Determined
Flash Point/Range (C):	Not Determined
Flash Point Method:	Not Determined
Autoignition Temperature (F):	Not Determined
Autoignition Temperature (C):	Not Determined
Flammability Limits in Air - Lower (%):	Not Determined
Flammability Limits in Air - Upper (%):	Not Determined

Fire Extinguishing Media — All standard firefighting media.

Special Exposure Hazards — Not applicable.

Special Protective Equipment for Fire-Fighters — Not applicable.

NFPA Ratings: Health 0, Flammability 0, Reactivity 0
HMIS Ratings: Health 0*, Flammability 0, Reactivity 0

6. ACCIDENTAL RELEASE MEASURES

Personal Precautionary Measures — Use appropriate protective equipment. Avoid creating and breathing dust.

Environmental Precautionary Measures — None known.

Procedure for Cleaning / Absorption	Collect using dustless method and hold for appropriate disposal. Consider possible toxic or fire hazards associated with contaminating substances and use appropriate methods for collection, storage and disposal.

7. HANDLING AND STORAGE

Handling Precautions	This product contains quartz, cristobalite, and/or tridymite which may become airborne without a visible cloud. Avoid breathing dust. Avoid creating dusty conditions. Use only with adequate ventilation to keep exposure below recommended exposure limits. Wear a NIOSH certified, European Standard En 149, or equivalent respirator when using this product. Material is slippery when wet.
Storage Information	Use good housekeeping in storage and work areas to prevent accumulation of dust. Close container when not in use. Do not reuse empty container. Product has a shelf life of 12 months.

8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Engineering Controls	Use approved industrial ventilation and local exhaust as required to maintain exposures below applicable exposure limits listed in Section 2.
Personal Protective Equipment	If engineering controls and work practices cannot prevent excessive exposures, the selection and proper use of personal protective equipment should be determined by an industrial hygienist or other qualified professional based on the specific application of this product.
Respiratory Protection	Wear a NIOSH certified, European Standard EN 149, or equivalent respirator when using this product.
Hand Protection	Normal work gloves.
Skin Protection	Wear clothing appropriate for the work environment. Dusty clothing should be laundered before reuse. Use precautionary measures to avoid creating dust when removing or laundering clothing.
Eye Protection	Wear safety glasses or goggles to protect against exposure.
Other Precautions	None known.

9. PHYSICAL AND CHEMICAL PROPERTIES

Physical State:	Solid
Color:	Various
Odor:	Odorless
pH:	7.5
Specific Gravity @ 20 C (Water=1):	2.12
Density @ 20 C (lbs./gallon):	Not Determined
Bulk Density @ 20 C (lbs/ft3):	51
Boiling Point/Range (F):	Not Determined
Boiling Point/Range (C):	Not Determined
Freezing Point/Range (F):	Not Determined
Freezing Point/Range (C):	Not Determined
Vapor Pressure @ 20 C (mmHg):	Not Determined
Vapor Density (Air=1):	Not Determined
Percent Volatiles:	Not Determined
Evaporation Rate (Butyl Acetate=1):	Not Determined
Solubility in Water (g/100ml):	Insoluble
Solubility in Solvents (g/100ml):	Not Determined

9. PHYSICAL AND CHEMICAL PROPERTIES

VOCs (lbs./gallon):	Not Determined
Viscosity, Dynamic @ 20 C (centipoise):	Not Determined
Viscosity, Kinematic @ 20 C (centistrokes):	Not Determined
Partition Coefficient/n-Octanol/Water:	Not Determined
Molecular Weight (g/mole):	Not Determined

10. STABILITY AND REACTIVITY

Stability Data:	Stable
Hazardous Polymerization:	Will Not Occur
Conditions to Avoid	None anticipated
Incompatibility (Materials to Avoid)	Hydrofluoric acid.
Hazardous Decomposition Products	Amorphous silica may transform at elevated temperatures to tridymite (870 C) or cristobalite (1470 C).
Additional Guidelines	Not Applicable

11. TOXICOLOGICAL INFORMATION

Principle Route of Exposure	Eye or skin contact, inhalation.
Inhalation	Inhaled crystalline silica in the form of quartz or cristobalite from occupational sources is carcinogenic to humans (IARC, Group 1). There is sufficient evidence in experimental animals for the carcinogenicity of tridymite (IARC, Group 2A). Breathing silica dust may cause irritation of the nose, throat, and respiratory passages. Breathing silica dust may not cause noticeable injury or illness even though permanent lung damage may be occurring. Inhalation of dust may also have serious chronic health effects (See "Chronic Effects/Carcinogenicity" subsection below).
Skin Contact	May cause mechanical skin irritation.
Eye Contact	May cause eye irritation.
Ingestion	None known
Aggravated Medical Conditions	Individuals with respiratory disease, including but not limited to asthma and bronchitis, or subject to eye irritation, should not be exposed to quartz dust.

Chronic Effects/Carcinogenicity

Silicosis: Excessive inhalation of respirable crystalline silica dust may cause a progressive, disabling, and sometimes-fatal lung disease called silicosis. Symptoms include cough, shortness of breath, wheezing, non-specific chest illness, and reduced pulmonary function. This disease is exacerbated by smoking. Individuals with silicosis are predisposed to develop tuberculosis.

Cancer Status: The International Agency for Research on Cancer (IARC) has determined that crystalline silica inhaled in the form of quartz or cristobalite from occupational sources can cause lung cancer in humans (Group 1 - carcinogenic to humans) and has determined that there is sufficient evidence in experimental animals for the carcinogenicity of tridymite (Group 2A - possible carcinogen to humans). Refer to IARC Monograph 68, Silica, Some Silicates and Organic Fibres (June 1997) in conjunction with the use of these minerals. The National Toxicology Program classifies respirable crystalline silica as "Known to be a human carcinogen". Refer to the 9th Report on Carcinogens (2000). The American Conference of Governmental Industrial Hygienists (ACGIH) classifies crystalline silica, quartz, as a suspected human carcinogen (A2).

There is some evidence that breathing respirable crystalline silica or the disease silicosis is associated with an increased incidence of significant disease endpoints such as scleroderma (an immune system disorder manifested by scarring of the lungs, skin, and other internal organs) and kidney disease.

Other Information

For further information consult "Adverse Effects of Crystalline Silica Exposure" published by the American Thoracic Society Medical Section of the American Lung Association, American Journal of Respiratory and Critical Care Medicine, Volume 155, pages 761-768 (1997).

Toxicity Tests

Oral Toxicity:	Not determined
Dermal Toxicity:	Not determined
Inhalation Toxicity:	Not determined
Primary Irritation Effect:	Not determined
Carcinogenicity	Refer to IARC Monograph 68, Silica, Some Silicates and Organic Fibres (June 1997).
Genotoxicity:	Not determined
Reproductive / Developmental Toxicity:	Not determined

12. ECOLOGICAL INFORMATION

Mobility (Water/Soil/Air) Not determined

Persistence/Degradability Not determined

Bio-accumulation Not determined

Ecotoxicological Information

Acute Fish Toxicity: Not determined
Acute Crustaceans Toxicity: Not determined

Acute Algae Toxicity:	Not determined
Chemical Fate Information	Not determined
Other Information	Not applicable

13. DISPOSAL CONSIDERATIONS

Disposal Method	If practical, recover and reclaim, recycle, or reuse by the guidelines of an approved local reuse program. Should contaminated product become a waste, dispose of in a licensed industrial landfill according to federal, state, and local regulations.
Contaminated Packaging	Follow all applicable national or local regulations.

14. TRANSPORT INFORMATION

Land Transportation

DOT
Not restricted

Canadian TDG
Not restricted

ADR
Not restricted

Air Transportation

ICAO/IATA
Not restricted

Sea Transportation

IMDG
Not restricted

Other Shipping Information

Labels: None

15. REGULATORY INFORMATION

US Regulations

US TSCA Inventory	All components listed on inventory or are exempt.
EPA SARA Title III Extremely Hazardous Substances	Not applicable
EPA SARA (311,312) Hazard Class	Acute Health Hazard Chronic Health Hazard
EPA SARA (313) Chemicals	This product does not contain a toxic chemical for routine annual "Toxic Chemical Release Reporting" under Section 313 (40 CFR 372).

EPA CERCLA/Superfund Reportable Spill Quantity	Not applicable.
EPA RCRA Hazardous Waste Classification	If product becomes a waste, it does NOT meet the criteria of a hazardous waste as defined by the US EPA.
California Proposition 65	The California Proposition 65 regulations apply to this product.
MA Right-to-Know Law	One or more components listed.
NJ Right-to-Know Law	One or more components listed.
PA Right-to-Know Law	One or more components listed.

Canadian Regulations

Canadian DSL Inventory	All components listed on inventory.
WHMIS Hazard Class	D2A Very Toxic Materials Crystalline silica

16. OTHER INFORMATION

The following sections have been revised since the last issue of this MSDS
Not applicable

Additional Information

*****END OF MSDS*****

HOLEPLUG®

Graded Sodium Bentonite

Description

HOLEPLUG® naturally occurring Wyoming sodium bentonite clay is a sized and graded chip material used to seal and plug earthen boreholes.

HOLEPLUG bentonite is available in two particle size grades:

- HOLEPLUG® 3/4" bentonite (100% of particles pass through 3/4" screen; all particles retained on 3/8" screen)
- HOLEPLUG® 3/8" bentonite (100% of particles pass through 3/8" screen; all particles retained on 1/4" screen)

Applications/Functions

The use of HOLEPLUG sodium bentonite assists or promotes the following:

- Grouting annulus in all types of wells, particularly environmental monitoring well applications
- Sealing above gravel packs
- Plugging decommissioned boreholes
- Stemming shotholes
- Sealing around conductor pipe
- Sealing lost circulation zones
- Shutting off artesian flow

Advantages

- Helps prevent entry of surface water into boreholes
- High swelling potential
- In situ swelling to provide a superior seal with excellent casing stabilization
- Easier to apply than pellets
- Cost effective
- Simple to apply, mixing not required
- Helps prevent vertical movement of fluids in the hole between porous zones
- Helps form a permanent, flexible downhole seal
- Helps allow hole re-entry
- Rehydratable
- NSF/ANSI Standard 60 certified

Typical Properties

Volume of 50-lb (22.7 kg) sack	
HOLEPLUG 3/4" bentonite	0.73 ft^3 or 0.027 yd^3 or 0.021 m^3
HOLEPLUG 3/8" bentonite	0.70 ft^3 or 0.026 yd^3 or 0.020 m^3
Permeability	1.5×10^{-9} cm/sec (in fresh water)
Appearance	Beige to tan chips

© Copyright 2011 Halliburton
HOLEPLUG is a registered trademark of Halliburton

Rev. 03/2011 · IDP 006

Because the conditions of use of this product are beyond the seller's control, the product is sold without warranty either express or implied and upon condition that purchaser make its own test to determine the suitability for purchaser's application. Purchaser assumes all risk of use and handling of this product. This product will be replaced if defective in manufacture or packaging or if damaged. Except for such replacement, seller is not liable for any damages caused by this product or its use. The statements and recommendations made herein are believed to be accurate. No guarantee of their accuracy is made, however.

Recommended Treatment

Plugging and Stemming Drill Holes

Due to shipping and handling, a small amount of fine bentonite particles may be present. For optimum results, HOLEPLUG® should be poured over a mesh or screen with ¼" (6.4 mm) openings to "sift out" the smaller particles. The screen should be large enough (approx.1 yd^2 or $1m^2$) to be folded into a "V" shape to allow sifting while the product is being poured into the hole. Also, HOLEPLUG bentonite should be poured slowly. Allow approximately two minutes to pour a 50-lb (22.7 kg) bag.

1. Position the screen with the lower end placed over the borehole
2. Slowly pour HOLEPLUG bentonite down the "V" so that fine particles fall through the screen before the larger particles fall into the borehole
3. Fill hole as required (above static water level or to ground level)
4. Observe all regulatory specifications

Stopping loss of circulation and stabilizing unconsolidated formations

1. Pull drill pipe out of hole
2. Pour HOLEPLUG bentonite into hole to fill above problem zone
3. Drill ahead slowly with reduced pump pressure

Plugging flowing wells

Pour HOLEPLUG bentonite into hole until water flow subsides or hole is filled to surface.

Treatment Considerations

- Adequate annular space, at least two inches on either side of the outside dimension of the casing, should be present to facilitate placement of HOLEPLUG bentonite into the desired area without bridging. The use of a tremie line may be necessary to ensure proper placement and is recommended for placement in deep hole applications.
- The grouting material and method selected will depend upon the specific subsurface environment including all prevailing geological and hydrological factors and any existing regulatory requirements.
- The use of bentonite may not be appropriate in environments where the formation water chemistry has a total hardness greater than 500 parts per million and/or a chloride content of greater than 1500 parts per million.
- If questions arise regarding subsurface environments it is always best to consult your local Baroid IDP representative to determine if the Baroid product of choice is appropriate for the given conditions.

Packaging

HOLEPLUG graded sodium bentonite is packaged in 50-lb (22.7 kg) multiwall paper bags.

Availability

HOLEPLUG graded sodium bentonite can be purchased through any Baroid Industrial Drilling Products Retailer. To locate the Baroid IDP retailer nearest you contact the Customer Service Department in Houston or your area IDP Sales Representative.

2. COMPOSITION/INFORMATION ON INGREDIENTS

SUBSTANCE	CAS Number	PERCENT	ACGIH TLV-TWA	OSHA PEL-TWA
Ammonium bisulfate	7783-20-2	1 - 5%	Not applicable	Not applicable
Bentonite	1302-78-9	60 - 100%	Not applicable	Not applicable
Crystalline silica, tridymite	15468-32-3	0 - 1%	0.05 mg/m^3	$1/2 \times \frac{10\ mg/m^3}{\%SiO2 + 2}$
Crystalline silica, cristobalite	14464-46-1	0 - 1%	0.025 mg/m^3	$1/2 \times \frac{10\ mg/m^3}{\%SiO2 + 2}$
Crystalline silica, quartz	14808-60-7	1 - 5%	0.025 mg/m^3	$\frac{10\ mg/m^3}{\%SiO2 + 2}$

3. HAZARDS IDENTIFICATION

Hazard Overview

CAUTION! - ACUTE HEALTH HAZARD
May cause eye and respiratory irritation.

DANGER! - CHRONIC HEALTH HAZARD
Breathing crystalline silica can cause lung disease, including silicosis and lung cancer. Crystalline silica has also been associated with scleroderma and kidney disease.

This product contains quartz, cristobalite, and/or tridymite which may become airborne without a visible cloud. Avoid breathing dust. Avoid creating dusty conditions. Use only with adequate ventilation to keep exposures below recommended exposure limits. Wear a NIOSH certified, European Standard EN 149, or equivalent respirator when using this product. Review the Material Safety Data Sheet (MSDS) for this product, which has been provided to your employer.

4. FIRST AID MEASURES

Inhalation	If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.
Skin	Wash with soap and water. Get medical attention if irritation persists.
Eyes	In case of contact, immediately flush eyes with plenty of water for at least 15 minutes and get medical attention if irritation persists.
Ingestion	Under normal conditions, first aid procedures are not required.
Notes to Physician	Treat symptomatically.

5. FIRE FIGHTING MEASURES

Flash Point/Range (F):	Not Determined
Flash Point/Range (C):	Not Determined
Flash Point Method:	Not Determined
Autoignition Temperature (F):	Not Determined
Autoignition Temperature (C):	Not Determined
Flammability Limits in Air - Lower (%):	Not Determined
Flammability Limits in Air - Upper (%):	Not Determined

Fire Extinguishing Media	All standard firefighting media.
Special Exposure Hazards	Not applicable.
Special Protective Equipment for Fire-Fighters	Not applicable.
NFPA Ratings:	Health 0, Flammability 0, Reactivity 0
HMIS Ratings:	Health 0*, Flammability 0, Reactivity 0

6. ACCIDENTAL RELEASE MEASURES

Personal Precautionary Measures	Use appropriate protective equipment. Avoid creating and breathing dust.
Environmental Precautionary Measures	None known.
Procedure for Cleaning / Absorption	Collect using dustless method and hold for appropriate disposal. Consider possible toxic or fire hazards associated with contaminating substances and use appropriate methods for collection, storage and disposal.

7. HANDLING AND STORAGE

Handling Precautions	This product contains quartz, cristobalite, and/or tridymite which may become airborne without a visible cloud. Avoid breathing dust. Avoid creating dusty conditions. Use only with adequate ventilation to keep exposure below recommended exposure limits. Wear a NIOSH certified, European Standard En 149, or equivalent respirator when using this product. Material is slippery when wet.
Storage Information	Use good housekeeping in storage and work areas to prevent accumulation of dust. Close container when not in use. Do not reuse empty container.

8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Engineering Controls	Use approved industrial ventilation and local exhaust as required to maintain exposures below applicable exposure limits listed in Section 2.
Personal Protective Equipment	If engineering controls and work practices cannot prevent excessive exposures, the selection and proper use of personal protective equipment should be determined by an industrial hygienist or other qualified professional based on the specific application of this product.
Respiratory Protection	Wear a NIOSH certified, European Standard EN 149, or equivalent respirator when using this product.
Hand Protection	Normal work gloves.
Skin Protection	Wear clothing appropriate for the work environment. Dusty clothing should be laundered before reuse. Use precautionary measures to avoid creating dust when removing or laundering clothing.
Eye Protection	Wear safety glasses or goggles to protect against exposure.
Other Precautions	None known.

9. PHYSICAL AND CHEMICAL PROPERTIES

Physical State:	Solid
Color:	Beige to Tan
Odor:	Odorless
pH:	8-10
Specific Gravity @ 20 C (Water=1):	2.5
Density @ 20 C (lbs./gallon):	Not Determined
Bulk Density @ 20 C (lbs/ft3):	74
Boiling Point/Range (F):	Not Determined
Boiling Point/Range (C):	Not Determined
Freezing Point/Range (F):	Not Determined
Freezing Point/Range (C):	Not Determined
Vapor Pressure @ 20 C (mmHg):	Not Determined
Vapor Density (Air=1):	Not Determined
Percent Volatiles:	Not Determined
Evaporation Rate (Butyl Acetate=1):	Not Determined
Solubility in Water (g/100ml):	Insoluble
Solubility in Solvents (g/100ml):	Not Determined
VOCs (lbs./gallon):	Not Determined
Viscosity, Dynamic @ 20 C (centipoise):	Not Determined
Viscosity, Kinematic @ 20 C (centistrokes):	Not Determined
Partition Coefficient/n-Octanol/Water:	Not Determined
Molecular Weight (g/mole):	Not Determined

10. STABILITY AND REACTIVITY

Stability Data:	Stable
Hazardous Polymerization:	Will Not Occur
Conditions to Avoid	None anticipated
Incompatibility (Materials to Avoid)	Copper and copper alloys. Zinc.

Hazardous Decomposition Products	Oxides of sulfur. Oxides of nitrogen. Ammonia. Amorphous silica may transform at elevated temperatures to tridymite (870 C) or cristobalite (1470 C).
Additional Guidelines	Not Applicable

11. TOXICOLOGICAL INFORMATION

Principle Route of Exposure	Eye or skin contact, inhalation.
Inhalation	Inhaled crystalline silica in the form of quartz or cristobalite from occupational sources is carcinogenic to humans (IARC, Group 1). There is sufficient evidence in experimental animals for the carcinogenicity of tridymite (IARC, Group 2A). Breathing silica dust may cause irritation of the nose, throat, and respiratory passages. Breathing silica dust may not cause noticeable injury or illness even though permanent lung damage may be occurring. Inhalation of dust may also have serious chronic health effects (See "Chronic Effects/Carcinogenicity" subsection below).
Skin Contact	May cause mechanical skin irritation.
Eye Contact	May cause eye irritation.
Ingestion	None known
Aggravated Medical Conditions	Individuals with respiratory disease, including but not limited to asthma and bronchitis, or subject to eye irritation, should not be exposed to quartz dust.
Chronic Effects/Carcinogenicity	Silicosis: Excessive inhalation of respirable crystalline silica dust may cause a progressive, disabling, and sometimes-fatal lung disease called silicosis. Symptoms include cough, shortness of breath, wheezing, non-specific chest illness, and reduced pulmonary function. This disease is exacerbated by smoking. Individuals with silicosis are predisposed to develop tuberculosis. Cancer Status: The International Agency for Research on Cancer (IARC) has determined that crystalline silica inhaled in the form of quartz or cristobalite from occupational sources can cause lung cancer in humans (Group 1 - carcinogenic to humans) and has determined that there is sufficient evidence in experimental animals for the carcinogenicity of tridymite (Group 2A - possible carcinogen to humans). Refer to IARC Monograph 68, Silica, Some Silicates and Organic Fibres (June 1997) in conjunction with the use of these minerals. The National Toxicology Program classifies respirable crystalline silica as "Known to be a human carcinogen". Refer to the 9th Report on Carcinogens (2000). The American Conference of Governmental Industrial Hygienists (ACGIH) classifies crystalline silica, quartz, as a suspected human carcinogen (A2). There is some evidence that breathing respirable crystalline silica or the disease silicosis is associated with an increased incidence of significant disease endpoints such as scleroderma (an immune system disorder manifested by scarring of the lungs, skin, and other internal organs) and kidney disease.
Other Information	For further information consult "Adverse Effects of Crystalline Silica Exposure" published by the American Thoracic Society Medical Section of the American Lung Association, American Journal of Respiratory and Critical Care Medicine, Volume 155, pages 761-768 (1997).
Toxicity Tests	

Oral Toxicity:	Not determined
Dermal Toxicity:	Not determined
Inhalation Toxicity:	Not determined
Primary Irritation Effect:	Not determined
Carcinogenicity	Refer to IARC Monograph 68, Silica, Some Silicates and Organic Fibres (June 1997).
Genotoxicity:	Not determined
Reproductive / Developmental Toxicity:	Not determined

12. ECOLOGICAL INFORMATION

Mobility (Water/Soil/Air)	Not determined
Persistence/Degradability	Not determined
Bio-accumulation	Not Determined

Ecotoxicological Information

Acute Fish Toxicity:	Not determined
Acute Crustaceans Toxicity:	Not determined
Acute Algae Toxicity:	Not determined
Chemical Fate Information	Not determined
Other Information	Not applicable

13. DISPOSAL CONSIDERATIONS

Disposal Method	If practical, recover and reclaim, recycle, or reuse by the guidelines of an approved local reuse program. Should contaminated product become a waste, dispose of in a licensed industrial landfill according to federal, state, and local regulations.
Contaminated Packaging	Follow all applicable national or local regulations.

14. TRANSPORT INFORMATION

QUIK-GROUT®

One-Sack Borehole Grouting and Plugging Material

Description

QUIK-GROUT is a single-sack, easy-to-use, sodium-based bentonite grout designed for grouting water wells, monitoring wells, and for plugging holes. QUIK-GROUT does not contain any polymers.

Applications/Functions

- Seal or grout plastic and steel casings
- Seal downhole instrumentation in test and observation holes
- Plug abandoned boreholes and earthen cavities

Note: Not recommended for use as a cement additive

Advantages

- Easy one-sack, dust-free mixing
- Develops a 20% active solids slurry weighing 9.4 lb/gal (1.13 g/cm^3) with hydrostatic gradient of 0.489 psi/ft (11.1 kPa/meter)
- Mix and handle with conventional rig equipment
- Creates a low permeability seal
- Develops a permanent, flexible seal to prevent commingling between aquifers
- Prevent entry of contaminants from the surface
- Rehydratable
- No heat of hydration
- NSF/ANSI Standard 60 certified

Typical Properties

Appearance	Beige to tan granular
Specific gravity	2.6
pH (8% slurry)	8.2
Electrical Resistivity, ohm-meter	0.98
Yield Volume gal/sack (liters/sack)	26.3 (99.5)
Permeability	2.5 x 10^{-8} cm/sec (in fresh water)

Recommended Treatment

QUIK-GROUT should be mixed with fresh water to obtain maximum results. The recommended mixing rate is a 50-lb (22.7 kg) sack of QUIK-GROUT with 24 gallons (91 liters) of fresh water to create a 20% active solids by weight grout with a density of 9.4 lb/gal or 1.13 g/cm^3.

QUIK-GROUT is a registered trademark of Halliburton

Rev. 10/2006 · IDP 023

Because the conditions of use of this product are beyond the seller's control, the product is sold without warranty either express or implied and upon condition that purchaser make its own test to determine the suitability for purchaser's application. Purchaser assumes all risk of use and handling of this product. This product will be replaced if defective in manufacture or packaging or if damaged. Except for such replacement, seller is not liable for any damages caused by this product or its use. The statements and recommendations made herein are believed to be accurate. No guarantee of their accuracy is made, however.

Recommended Mixing Procedure

- Using a mixing device, blend one sack of QUIK-GROUT® into 24 gallons (91 liters) of fresh water. Rate of addition should be about 20 to 30 seconds per 50-lb (22.7 kg) bag.
- Blend, do not over mix and do not use a centrifugal pump. The resulting slurry should have an oatmeal consistency containing unyielded or partially yielded bentonite. Pump through tremie into hole without delay.

Note:

- The grouting method selected will depend upon, and you should carefully consider, all prevailing geological and hydrological factors and any existing regulatory requirements. The grouting process may not be complete until the grout is static at the desired level.
- The subsurface environment that the respective bentonite sealing material or grout is to be placed into should always be taken into consideration when selecting the appropriate material to compose the well seal. If the formation water chemistry has a total hardness of greater than or equal to 500 parts per million and/or a chloride content of greater than or equal to 1500 parts per million the use of a bentonite material may not be appropriate for this environment. In the event that questions regarding subsurface environments arise it is always best to consult your local Baroid IDP representative to determine if the Baroid product of choice is appropriate for the given conditions.

Packaging

QUIK-GROUT is packaged in 50-lb (22.7 kg) multiwall paper bags, containing 0.7 ft^3 (0.02 m^3).

Availability

QUIK-GROUT can be purchased through any Baroid Industrial Drilling Products Retailer. To locate the Baroid IDP retailer nearest you contact the Customer Service Department in Houston or your area IDP Sales Representative.

FLUSH THREAD PVC SCREEN AND CASING

- ✓ Monoflex CNC computer lathed flush threads follow ASTM F-480 recommendations for reliable, consistent results on the job site.
- ✓ Our close tolerances provide a strong connection while retaining ease of assembly.
- ✓ Manufactured from quality PVC pipe, Monoflex flush thread screens and casings are available in diameters of 1/2" through 16" with 2, 4, or 8 threads per inch in Sch. 40 & Sch. 80. Other schedules and SDR's are available in PVC and high density polyethylene.
- ✓ Lengths are measured as "laying length", (not including male thread length), in 2" and 4" diameters, Sch. 40 and Sch. 80 and 6" Sch. 80. All other diameters and schedules are measured end to end. Custom lengths are available in all diameters.
- ✓ All standard Monoflex PVC threads are compatible with other materials threaded to ASTM F-480 recommendations, with the same TPI. **Note**: Threads on 14" and 16" Monoflex screens and casings are not ASTM F-480 as the flush thread guideline does not specify pipe diameters larger than 12".
- ✓ All standard screens provide maximum net open area. A wide variety of slot sizes and spacings are available to adapt to various site conditions and applications.
- ✓ 1/2" through 6" Sch. 40 and Sch. 80 screens and casings are provided with Buna-N O-rings. O-rings may be installed or packaged separately depending on size. O-rings for all other sizes and schedules are sold separately. Please specify if O-rings are required when placing order.
- ✓ All flush thread screens and casings are Envirowrapped and hermetically sealed at both ends as a standard practice.

The following pages list flush thread PVC screens and casings along with the appropriate Buna-N O-rings, and flush thread caps, plugs, and points. Custom lengths, threads and adapters are available.

Please specify part number when ordering.

ENGINEERING SPECIFICATIONS

PVC FLUSH THREAD MONITOR WELL SCREENS AND CASINGS

1. All PVC well screens and casings used on this project shall be manufactured by Monoflex and conform to ASTM F-480: "Standard Specification for Thermoplastic Well Casing Pipe and Couplings Made in Standard Dimension Ratios (SDR), SCH 40 and SCH 80."
2. PVC materials used to produce the raw PVC pipe shall meet ASTM Standard D-1784: "Specification for Rigid Poly (Vinyl Chloride) (PVC) Compounds and Chlorinated Poly (Vinyl Chloride) (CPVC) Compounds for PVC Normal Impact, Type I Grade I (1120), cell classification 12454-B."
3. The finished schedules 40, 80, and 120 raw pipe shall meet the requirements of ASTM Standard D-1785: "Specification for Poly (Vinyl Chloride) (PVC) Plastic Pipe, Schedules 40, 80, and 120." In addition, both the raw material and the finished raw pipe shall be approved by the National Sanitation Foundation (NSF) for use in potable water applications.
4. The PVC pipe used to produce the well screens and casings shall be made from virgin plastic produced by the original compounder.
5. The pipe shall be homogeneous throughout and essentially uniform in color, opacity and density. The inside and outside surfaces shall be glossy in appearance and free of chalking, sticky or tacky material and visually free of oils, grease, dust and marks imparted as a result of the manufacturing process. In addition the pipe walls shall be free of ink, cracks, holes, blisters, voids, foreign inclusions, or other defects that are visible to the naked eye and that may affect the wall integrity. Machined slots or holes deliberately placed in the pipe are acceptable.
6. The outside diameters, wall thicknesses and out of roundness tolerances shall fall within the guidelines of Tables 1 & 2 of the ASTM F-480 Standard Specification when measured in accordance with Test Method D-2122.
7. All flush thread materials must be slotted and threaded without the use of any type of liquid coolant. Air is the only acceptable coolant.
8. Well screens 1/2" through 5" are to be slotted on 1/8" spacing. Well screens 6" and larger are to be slotted on 1/4" spacing unless otherwise specified. ALL well screens .040 slot and larger will be slotted on 1/4" spacing unless otherwise specified.
9. All screens and casings shall be nominal length except for 2" and 4" sch. 40 and 6" sch. 80 which shall be laying length. The term "laying length" refers to the overall length less the length required to complete the assembly.
10. The threads per inch for the various diameters and schedules of flush thread materials shall be the same as that produced by Monoflex, Bechtelsville, Pennsylvania or approved equal.
11. All flush thread screens & casings shall be supplied in individual polyethylene bags hermetically sealed at BOTH ends. Said products shall be shipped in cardboard boxes with properly secured ends. Each box shall display a color coded label containing a full description of the product inside. Said label must indicate the number of pieces per box, the threads per inch, the date of packaging, the signatures of the packer and QC inspector and show a drawing of the product.

Stainless Steel Centralizers

The Bear Stainless Steel Centralizers are made from durable 201 Stainless Steel and feature an industry unique eyebolt fastening design that is highly sought after by field installation crews. The centralizers are made to easily fit around the center pipe and maintain its position in the center of the riser as it is fed down-hole.

Product Option:

- Stainless Steel Centralizers are also available in Heavy Duty 301Stainless Steel for heavier pipe
- Centralizers are also available in PVC
- Please contact our Sales Staff for any custom application

SECTION 02145

GROUNDWATER MONITORING WELL CONSTRUCTION

PART 1 - GENERAL

1.1 RELATED DOCUMENTS

A. Drawings, General Conditions of the Contract for Construction, Supplementary Conditions and Division 1 – General Requirements apply to the work of this Section.

1.2 REFERENCES

The publications listed below form a part of this specification to the extent referenced. The publications are referred to in the text by the basic designation, title or are used to establish criteria. The latest publication in use at the time of the executed contract shall be the one used on this project.

A. AMERICAN SOCIETY FOR TESTING AND MATERIALS (ASTM)
   1. ASTM C150 Standard Specification for Portland Cement.
   2. ASTM F480 Standard Specification for Thermoplastic Well Casing Pipe and Couplings made in SDR, SCH40 and SCH80.

B. TEXAS COMMISSION ON ENVIRONMENTAL QUALITY (TCEQ)
   1. Owner's MSW Permit
   2. 30 TAC §330.421 Monitor Well Construction Specification.

1.3 RELATED SECTIONS

A. Section 03300 – Cast-In-Place Concrete.

1.4 SUMMARY

A. These specifications describe the installation of two (2) new piezometers and one (1) new groundwater monitoring wells. The piezometers shall be installed to groundwater monitoring well standards. The new wells will be drilled at the specific site locations designated on the plans. Well installation and development shall be performed by a qualified monitor well driller licensed in the State of Texas, experienced specifically in the installation of landfill monitoring wells. Installation and development will be supervised by a licensed professional engineer that the Engineer hires who is familiar with the geology of the area.

B. Each well and piezometer will require 20-feet of screen. Well and piezometer depths range from approximately 403 feet to 459 feet in depth.

1.5 REPORTS

A. The Contractor is required to submit detailed geologic information from each well, a description of development procedures, any particle size or other sample data from the well, and all forms required by TCEQ or other agencies to the Owner and Engineer within 10 days after completion of the monitor well installation. Forms the Contractor will complete to TCEQ, and provide to Engineer in addition to the State of Texas Well Report, are included in Appendix A.

1.6 SURVEY

A. The owner will provide survey hubs near each location for final elevation verification.
B. It will be the Contractor's responsibility to protect the hubs during construction. All survey work in setting the final elevations will be accomplished by a licensed professional surveyor employed by the Owner. Any off-set hubs that are lost or damaged by the Contractor will be replaced at the Contractor's expense.

PART 2 - PRODUCTS

2.1 CASING MATERIAL

A. The casing shall be 4-inch nominal diameter and shall be new National Science Foundation certified polyvinyl chloride (PVC) Schedule 80 pipe (ASTM F480). The casing shall be furnished with flush-threaded ends, screw joints (no glue or solvents are allowed), and in such lengths that they can be properly handled and aligned with the equipment. Polytetrafluorethylene (PTF) or O-rings shall be used at all casing joints. Collar couplings are not allowed. No cement glue or solvent joints are permitted. No inks, labels, or other manufacturer markings will be permitted on the casing. The contractor shall provide a manufacturer's affidavit which states the ASTM specification to which the casing complies. The casing shall be cleaned and packaged at the place of manufacture; the packaging shall include a PVC wrapping on each section of casing to keep it from being contaminated prior to installation.

2.2 WELL SCREEN MATERIAL

A. The well screen shall be 4-inch nominal diameter and shall be new National Science Foundation certified polyvinyl chloride (PVC) Schedule 80 pipe (ASTM F480). All materials shall be prime quality and no rejects or limited service pipe will be acceptable. All screen pipe shall be furnished with threaded flush ends and screw joints. No cement glue or solvent joints are permitted. Screen pipe shall be free of ink, labels or other markings. Screen pipe shall be furnished in such lengths that they can be properly handled and aligned with the equipment. The Contractor shall provide a manufacturer's affidavit which states the ASTM specification to which the screen complies.
B. The slot opening size shall be 0.010 inches wide by 2 inches long. There shall be 4 rows of slots along the entire length of the screen with 44 slot openings per row per foot of length of pipe. The well screen shall be of sufficient size and design to hold back and support the filter pack material. The openings shall be smooth, sharp-edged and free of any burns, chipped edges or broken pieces on the interior and exterior surface of the pipe and the openings shall not be larger than the smallest fraction of filter pack. Field constructed screen (field-cut slots) is not acceptable. Filter cloth shall not be used. The plastic pipe screen strength properties shall be equivalent to those for the plastic casing with which the screen is used. The pattern of the openings shall be uniformly spaced around the periphery of the well screen.
C. A two (2) foot length of blank screen or casing shall be used at the base of the screen as a sediment trap. The material used shall be the same material used for casing and screen.

2.3 FILTER PACK

A. Material for filter packing the wells shall consist of prepackaged, inert, clean 10/20 silica sand or glass beads. Open stockpile sources of sand or gravel are not permitted. All equipment that comes into direct contact with the filter material shall not introduce any contaminant into the material. Any filter material contaminated by Contractor efforts shall be properly disposed and replaced at the Contractor's expense.

2.4 BENTONITE ANNULAR SEAL

A. Annular seal shall consist of coarse-grain or coarse-grit sodium bentonite pellets, having a nominal dimension of 3/8-inch. The bentonite used will be of the variety normally used in water well operations. Irregular bentonite pellets, i.e. "Hole Plug" by trade name, may be used unless the Engineer determines that the material will not flow properly into place. Bentonite grout may also be utilized for the annular seal.

2.5 CASING SEAL

A. The casing seal shall consist of either a bentonite grout or a cement-bentonite mixture placed on top of the annular seal. Drilling spools, cuttings, or other native materials are not permitted for use as a casing seal. Quick-setting cements are not permitted because contaminants may leach from them into the groundwater. If a cement bentonite mixture is used, the cement shall conform to ASTM C150, Type I or II. The mixture shall be proportioned in the amount of 5.2 gallons of water to 94 pounds of cement. Combine four (4) or five (5) pounds of bentonite powder by weight with the cement/water mixture. Water used shall be free of oil and other organic material. Dissolved minerals in the water should be less than 2,000 mg/1.

2.6 CASING PLUG

A. The top of the casing shall be protected by a threaded or slip-on top cap or by a sealing cap or screw-plug seal inserted into the top of the casing. The casing plug shall be a Universal Valve Co. model number 1300-40 or approved equal. The cap shall be vented to prevent buildup of methane or other gases and shall be designed to prevent moisture from entering the well.

2.7 PORTLAND CEMENT CONCRETE

A. Concrete shall be high-quality structural-type concrete and shall conform to Section 03300.

2.8 PROTECTIVE STEEL COLLAR

A. Provide an 8-inch steel pipe with a lockable hinged top flap or cover as shown on the plans. Owner will furnish locks for each that are to be maintained in working order, and kept locked when the well is not being purged or sampled. Each master lock for the wells will be operational with the same key. Square shaped protective collars, 8-inch by 8-inch, may be acceptable upon Engineers approval. Wall thickness and fabrication must be comparable to pipe collars.

2.9 BOLLARD

A. Provide 6-inch (Sch. 40) steel pipe filled with Portland cement concrete as shown on the plans.

PART 3 - EXECUTION

3.1 SLUSH PITS

A. The Contractor shall provide, if necessary, slush pits and drainage ditches. Slush pits and drainage ditches shall be excavated as required and, after completion of each well, the slush pits and drainage ditches shall be filled and all sand, muck, and other unsuitable materials shall be removed from the site and the entire area regraded to approximately its original condition. Slush pit locations shall be coordinated with the Owner to cause the minimum damage to the adjacent areas and simultaneous construction by others.

3.2 GROUNDWATER MONITORING WELL CONSTRUCTION

A. Decontamination:
   1. Prior to drilling each hole, all drilling equipment must be decontaminated by steam cleaning with equipment approved for use by the Engineer. Care must be taken not to introduce contaminants (grease, diesel fuel, drilling mud, drill stem thread lubricants, solvents, contaminated water, etc.). Any drilling fluid used other than a TCEQ approved city water source must be approved by the Engineer or Owner before use at Contractor's expense. If city water is used, a current chemical analysis of the city water shall be provided with the monitor well report. Also, decontaminate all casing, screens, bailers, pumps, piping, etc., before placing in bore hole.

B. Drilling:
   1. Drilling and well construction shall be performed using Air Rotary Casing Hammer (ARCH) drilling methods, which are capable of driving casing into an undersized bore to the required depth. Drill casing shall be a heavy wall, flush threaded pipe, no welded drive casing will be allowed. The drill rig shall be required to have an on-board air compressor with a minimum capacity of 1,050 scfm at 350 psi. The well and annular materials shall be placed inside of the drive casing and the casing removed as the construction materials are added. The hydraulic casing puller, used to remove the drive casing during well construction, shall be rated at a minimum of 250 tons of pull back capacity. The well shall be drilled, cased and developed in a workmanlike manner. The well shall be drilled straight and plumb within the limits specified. The plumbness of the well shall be such that the variation from truly vertical does not vary more than one-half of one degree at any point being tested. The Contractor shall make such checks of the hole while drilling is in progress as he may deem necessary to maintain the proper alignment and plumbness of the hole.
   2. When groundwater is encountered, drilling operations shall be suspended for 24-hours to allow for stabilization of the static groundwater level. At the end of the 24-hour period, the driller shall take a static groundwater measurement, in the presence of the Engineer, and submit that information to the Engineer. Once the stabilized groundwater depth has been recorded by the Engineer, drilling will resume at the direction of the Engineer.
   3. From the ground surface to bottom of each planned well, the bore hole diameter shall be a minimum of 4-inches larger than the diameter of the PVC casing and screen.

C. Samples and Drilling Log:
   1. A careful log of each hole drilled shall be prepared and signed by the driller. The log shall describe in detail each formation found, with sample number and depth, the depth to each water-bearing formation found, and the static water level in the well. The

soils/sediments encountered will be visually classified in the field using the Unified Soils Classification System.

D. Casing and Screen:
   1. The Contractor shall furnish and set all casing and well screen required for the construction of the wells. The well screens shall be directly connected to the casing.
   2. The solid casing and well screen shall be set as soon as drilling is completed and shall extend from the bottom of the drilled hole to above the existing ground as shown on the plans. The casing shall be set truly vertical and centered in the hole. Well casing and screen shall have approved centering devices spaced 120 degrees apart at intervals not exceeding 40-feet along the length of the screen and casing.

E. Filter Pack:
   1. As soon as the casing has been set, the space between the casing and the wall of the well shall be filled with an approved filter pack by Tremie tube. The filter pack shall be tremied into the annulus in maximum 20-foot lifts so that the maximum distance between the bottom of the tremie tube and the top of the filter pack is never greater than 20-feet. The method shall be such that the material is uniformly placed around the casing to the desired thickness. The process shall be continued until the filter pack is five (5) feet above the well screen.

F. Annular Seal:
   1. The annular seal shall be placed above the gravel pack and shall be at least five feet thick. The seal will be placed within the zone of saturation to maintain hydration. The Contractor shall place the seal on top of the filter pack by Tremie tube. The method shall be such that the pellets are uniformly distributed around the casing to obtain the desired thickness. Verification of the uniformity shall be made. Once verification of uniformity is complete, the bentonite shall be hydrated with clean water and let stand for 12 hours. No bentonite is to be dropped into the well casing. Special care shall be taken to ensure that fine material or grout does not plug the filter below.

G. Casing Seal:
   1. The annular space between the casing and walls of the hole shall be filled with a high solids bentonite groute or a cement-bentonite slurry mixture in the upper region of each well above the annular seal. No method will be approved that does not specify the forcing of the slurry from the bottom of the space to be grouted toward the surface. Grouting shall be done in a continuous manner to insure that the entire annular space is filled in one operation. The cement-bentonite slurry will be placed from the top of the annular seal upward, to 2-feet from ground surface.

H. Development and Testing:
   1. Following construction, the well shall be developed until the water pumped from the well is substantially free from all artifacts of drilling (clay film, bentonite, sand, etc.). The well shall also be developed to open the water bearing zone for maximum flow into the well. Pumping shall continue until the turbidity is less than five (5) on the Jackson Turbidity Scale specified in AWWA Standard Methods for the Examination of Water and Wastewater. Developing equipment and additives shall be of an approved type and of sufficient capacity to remove all sand, rock cuttings, drilling fluid and wall cake and any other foreign material. Development shall not commence on any individual well unless that well has been grouted at least twenty-four (24) hours with the approved grout.
   2. In addition to turbidity, driller shall test for pH, specific conductance and temperature. Development shall continue until water runs clean and these field measurements have stabilized.

3.3 CONCRETE SEALING BLOCK

A. After completion of the well a concrete pad shall be constructed continuously from the top of the casing seal to the top of the ground in accordance with the plans. The pad shall be reinforced as shown on the plans. The top of the well foundation shall be given a smooth, neat finish with trowel and light brush. The slab will be constructed so as to drain away from the protective casing cover with a minimum slope of 1/4-inch per foot.

3.4 PROTECTIVE STEEL COLLAR AND CASING PLUG

A. The protective steel collar shall be set in the concrete sealing block during its construction, embedded to a minimum depth of two-feet and shall extend at least three inches above the top of the well casing (and top cap, if present). The well number or other designation shall be marked permanently on the protective steel collar.

3.5 BOLLARD

A. Construct the bollards so they form an independent protective barrier for the concrete cap and seal as shown on the plans.

3.6 CLEANING UP

A. After completion and testing of the well, the Contractor shall remove all debris including excess sand from the site, fill all slush pits and drainage ditches, and grade around the site, leveling all materials taken from the well during drilling so that the area is left in a neat condition. No separate payment will be made for cleaning up the site, the cost of such work shall be included in the bid price for pay items.

END OF SECTION

SECTION 03300

CAST-IN-PLACE CONCRETE

PART 1 - GENERAL

1.1 RELATED DOCUMENTS

A. Drawings, General Conditions of the Contract for Construction, Supplementary Conditions and Division 1 - General Requirements apply to work of this section.

1.2 SECTION INCLUDES

A. Cast-in-place concrete foundations, building frame members, and foundation walls.
B. Floors and slabs on grade.
C. Control, and expansion and contraction joint devices associated with concrete work.
D. Equipment pads.

1.3 REFERENCES

A. ACI 301 - Structural Concrete for Buildings.
B. ACI 302 - Guide for Concrete Floor and Slab Construction.
C. ACI 304 - Recommended Practice for Measuring, Mixing, Transporting and Placing Concrete.
D. ACI 305R - Hot Weather Concreting.
E. ACI 306R - Cold Weather Concreting.
F. ACI 308 - Standard Practice for Curing Concrete.
G. ACI 318 Building Code Requirements for Reinforced Concrete.
H. ASTM C33 - Concrete Aggregates.
I. ASTM C94 - Ready-Mixed Concrete.
J. ASTM C150 - Portland Cement.
K. ASTM C260 - Air Entraining Admixtures for Concrete.
L. ASTM C494 - Chemicals Admixtures for Concrete.
M. ASTM C618 - Fly Ash and Raw or Calcinated Natural Pozzolan for Use as a Mineral Admixture in Portland Cement Concrete.

1.4 SUBMITTALS

A. Submit under provisions of Section 01300.
B. Product Data: Provide data on joint devices, attachment accessories, admixtures and cement types to be used.
C. Manufacturer's Installation Instructions: Indicate installation procedures and interface required with adjacent Work.

1.5 QUALITY ASSURANCE

A. Perform Work in accordance with ACI 301.
B. Acquire cement and aggregate from same source for all work.
C. Conform to ACI 305R when concreting during hot weather.
D. Conform to ACI 306R when concreting during cold weather.

1.6 COORDINATION

A. Coordinate the placement of joint devices with erection of concrete formwork and placement of form accessories.

PART 2 - PRODUCTS

2.1 CONCRETE MATERIALS

A. Cement: ASTM C150, Type I - Normal, Type II - Moderate, Portland type. All cement shall be from the same manufacturer unless approved by the Engineer.
B. Fine and Coarse Aggregates: ASTM C33.
C. Water: Clean and not detrimental to concrete.

2.2 ADMIXTURES

A. Air Entrainment: ASTM C260.
B. Chemical: ASTM C494, Type A - Water Reducing; Type B - Retarding; Type C - Accelerating; Type D - Water Reducing and Retarding; Type E - Water Reducing and Accelerating admixture.
C. Fly Ash: ASTM C618.

2.3 CONCRETE MIX

A. Mix and deliver concrete in accordance with ASTM C94, Alternative No. 2 and 3.
B. Select proportions for normal weight concrete in accordance with ACI 301 Method 1, Method 2 and Method 3.
C. Provide concrete to the following criteria:
   1. Compressive Strength (28 days): 3,000 psi.
   2. Slump: 1 to 4 inches.
   3. Maximum Water/Cement Ratio: 0.50.
D. Use set retarding admixtures during hot weather only when approved by Engineer.
E. Add air entraining agent to normal weight concrete mix for work exposed to exterior.

PART 3 - EXECUTION

3.1 EXAMINATION

A. Verify requirements for concrete cover over reinforcement.
B. Verify that anchors, seats, plates, reinforcement and other items to be cast into concrete are accurately placed, positioned securely, and will not cause hardship in placing concrete.

3.2 PLACING CONCRETE

A. Place concrete in accordance with ACI 304.
B. Notify Engineer minimum 24 hours prior to commencement of operations.
C. Ensure reinforcement, inserts, embedded parts, formed joint fillers are not disturbed during concrete placement.

3.3 CONCRETE FINISHING

A. Provide formed concrete surfaces to be left exposed with smooth rubbed finish as Scheduled in this Section.
B. Finish concrete floor surfaces in accordance with ACI 301.
C. Steel trowel surfaces which are scheduled to be exposed.

3.4 CURING AND PROTECTION

A. Immediately after placement, protect concrete from premature drying, excessively hot or cold temperatures, and mechanical injury.
B. Maintain concrete with minimal moisture loss at relatively constant temperature for period necessary for hydration of cement and hardening of concrete.
C. Cure floor surfaces in accordance with ACI 308.

3.5 FIELD QUALITY CONTROL

A. Field inspection and testing will be performed in accordance with ACI 301.
B. Provide free access to Work and cooperate with appointed firm.
C. Submit proposed mix design of each class of concrete to Engineer for review prior to commencement of Work.
D. Tests of cement and aggregates may be performed to ensure conformance with specified requirements.

3.6 PATCHING

A. Allow Engineer to inspect concrete surfaces immediately upon removal of forms.
B. Excessive honeycomb or embedded debris in concrete is not acceptable. Notify Engineer upon discovery.
C. Patch imperfections as directed.

3.7 DEFECTIVE CONCRETE

A. Defective Concrete: Concrete not conforming to required lines, details, dimensions, tolerances or specified requirements.
B. Repair or replacement of defective concrete will be determined by the Engineer.
C. Do not patch, fill, touch-up, repair, or replace exposed concrete except upon express direction of Engineer for each individual area.

Re: Groundwater Monitoring System Installation
Additional Well Development Activities
City of El Paso McCombs Landfill - Permit No. MSW-729A
El Paso County, Texas

Dear Mr. Al-Dasouqi:

Raba-Kistner Consultants (SW), Inc. (Raba-Kistner) is pleased to submit this documentation of additional groundwater monitor well development activities at the above referenced facility. The groundwater monitoring system installation was documented in a previous letter report to the Texas Commission on Environmental Quality (TCEQ) dated December 18, 2003. As indicated in the letter report, additional groundwater monitor well development was recommended for the three recently installed monitor wells at the McCombs Landfill. Based on the recorded water quality parameters from the initial well development, it appeared that an insufficient water volume was initially purged to restore natural hydrogeological conditions. Therefore, the additional well development was performed to remove any residual drilling artifacts and restore the natural hydrogeological conditions.

DESCRIPTION OF ADDITIONAL DEVELOPMENT ACTIVITIES

Raba-Kistner completed the additional well development at each of the three monitoring wells at the above referenced site between January 19, 2004 and January 27, 2004. The well development was performed by Lirasa Drilling Company and Raba-Kistner observed and documented the well development activities.

On January 19 and January 20, 2004, 230 gallons of groundwater were removed from MW-1 using an approximate 2.5 gallon bailer. The groundwater removed from MW-1 was initially clear, however upon further development fine-grained sand with silt was observed to be present within the groundwater at MW-1. The fine-grained sand with silt did not appear to be artifacts of drilling mud or additives, but rather appeared to be naturally occurring sediments within the water bearing formation, which migrated with groundwater into MW-1. Groundwater samples were collected at discrete intervals during well development to monitor water quality parameters (pH, conductivity, turbidity, and temperature). Turbidity readings generally exceeded the range of the turbidity metar, which was 1000 NTUs. This may have been due to the agitated state of the fine-grained sand with silt in the groundwater. Development continued until 10 well volumes were removed and pH, conductivity and temperature readings stabilized (i.e. less than

10 percent variation for at least three consecutive readings). Upon completion of the additional well development activities at MW-1, a total of 360 gallons of groundwater was removed from MW-1.

On January 21, 2004, approximately 100 gallons of groundwater were removed from MW-2 using an approximate 5 gallon bailer. The groundwater removed from MW-2 was found to be clear with minimal fine-grained sand present. As indicated on the well development form the water quality parameters (pH, conductivity, and temperature) were found to have stabilized within 100 gallons of groundwater being removed from the wells. Upon completion of the well development activities a total of 360 gallons were removed from MW-2.

On January 21, 2004, approximately 35 gallons of groundwater were removed from MW-3 using an approximate 5 gallon bailer. After the 35 gallons were removed, minimal groundwater was observed in the bailer. Upon attempting to record the total depth of the well, an obstruction was encountered at a depth of 454.6 feet below ground surface. Development of MW-3 continued on January 23, 2004, using compressed air, however minimal groundwater was being removed from MW-3. Initially, medium to coarse grained sands were removed from MW-3 followed by fine grained sand and silt. Between approximately 4:05 and 4:08 p.m. on January 23, 2004, angular and subangular gravels with silt were removed from MW-3. The medium to coarse grained sands and gravels could not have entered through the 0.010-inch size slotted screen and the source of the materials could not be determined. Therefore, the presence of the gravels and minimal amount of groundwater presented an abnormal condition. After the gravels were removed from MW-3, minimal water with silt continued to be removed. On January 26, 2004, redevelopment of MW-3 continued and a connection was added to the top of the PVC casing to capture the development water. The water collected initially contained approximately 75 percent fine grained sands with silt and as development continued less fine grained sand was observed in the development water until the water was clear to cloudy with minimal sediment. On January 26, 2004 over 500 additional gallons of groundwater (13 well volumes) were removed using compressed air. Development continued on January 26 and 27, 2004 to remove any remaining sediment from the bottom of MW-3, however samples were not collected until development was completed on January 27, 2004. Although, the water quality parameters were found to have stabilized, the groundwater contained fine-grained sands. The fine-grained sands appear to be naturally occurring sediments within the water bearing formation, which have migrated with groundwater into MW-3. Upon completion of the additional well development activities at MW-3, a total of over 815 gallons of groundwater were removed from the well.

Water levels were gauged and recorded prior to and following well development of each of the monitoring wells. The volumes removed, water quality parameters and depths to groundwater can be found on the attached well development forms.

With the additional well development that was completed, Raba-Kistner concludes that the groundwater monitor wells have been properly developed in accordance with the well development requirements of 30 TAC 330.242 (c). Groundwater within the water bearing zone of the monitor wells has been restored to natural hydrogeological conditions.

Project No. ASF02-045-00
April 8, 2004

CLOSING

We trust that the information provided herein in conjunction with that provided previously in our letter report dated December 18, 2003, satisfies the groundwater monitoring system installation requirements for this site. If you have any questions or need additional information regarding the information included herein, please do not hesitate to contact either of the undersigned.

Respectfully submitted,

1/26/2004	3			20	515	8.55	Error	104	20.5	12:20	
1/26/2004	3			20	535	8.56	Error	144	20.4	12:25	pH and Temp have stabilized for 3 consecutive measurements. 13.9 well volumes were removed. See Note 5.
1/27/2004	3					8.66		470	23.4	2:20	Water is clear with minimal sand.
1/27/2004	3					8.61		390	22.9	2:30	
1/28/2004	3	491.33	388.10								Water level reading following development.
3/24/2004	3	493.85	389.54							4:15	Sand or silt observed on bottom 4-inches of water level indicator probe.
4/7/2004	3	493.03	389.70							9:20	Sand or silt observed on bottom 1-inch of water level indicator probe.

DESCRIBE THE DISPOSITION, AMOUNT, AND LOCATION OF PURGED WATER AND ANY OTHER COMMENTS:

1. The water level indicator could not extend beyond a depth of 454.6 feet and very little water was being recovered at this time, therefore bailing was discontinued at MW-3 on 1/21/04. Development on 1/21/04 was performed using a 5.0 gallon bailer.

2. On 1/23/04 development was continued using compressed air. However, no samples collected due to minimal water being removed. Fine, medium and coarse grained sands and silt were being removed from the well. Between 4:05 and 4:08 p.m., angular and subangular gravel with sand and silt was being blown out of well.

3. Well Volume = Volume of Casing within Screened Interval (20' x 0.6 gal/ft) + Effective Volume of Filter Pack (Volume of Filter Pack x 0.25)
Well Volume = 12.0 gallons + 28.4 gallons = 39.4 gallons

4. Parameters (pH, temp.) were considered stabilized when three consecutive readings were within 10 percent.

5. Additional water was removed on 1/26/04 and 1/27/04 to remove additional sediments from the bottom of MW-3. Samples were not collected and activities were not recorded.

6. Error = Parameter levels exceed limits of meter. Conductivity meter did not appear to be working properly even after recalibrating and troubleshooting.

TEXAS COMMISSION ON ENVIRONMENTAL QUALITY

Protecting Texas by Reducing and Preventing Pollution

March 12, 2004

The Honorable Joe Wardy
Mayor of El Paso
2 Civic Center Plaza
10th Floor
El Paso, TX 79901

Re: Municipal Solid Waste - El Paso County
City of El Paso/McCombs Landfill - MSW Permit No. 729A
Groundwater Monitor Well Installation Report
WWC No. 10443047, Mail Log No. 04-4140
RN100215599, 601410244

Dear Mayor Wardy:

On December 29, 2003, the Texas Commission on Environmental Quality (TCEQ) received the referenced report dated December 18, 2003, documenting the installation of monitor wells MW-1, MW-2, and MW-3 at the City of El Paso McCombs Landfill, as required by Attachment 5 (Groundwater Characterization Report) in the current Site Development Plan. The report was prepared by Raba-Kistner Consultants (SW), Inc., and was signed and sealed by Ms. Valerie A. Joosten, P.E. (#89118), Environmental Engineer. The report was also signed by Mr. Richard V. Klar, P.G., Environmental Geologist.

This report included a detailed site map drawn to scale depicting the new monitor well locations and the relevant point of compliance, detailed geologic boring logs, Monitor Well Data Sheets (Form TCEQ-10308), State of Texas Well Reports (Form TNRCC-0199), typical monitor well construction detail, generalized groundwater flow direction map, summary of groundwater level data, a current chemical analysis of city water used during drilling activities, well development forms, surveyor's certification, and a qualified groundwater scientist certification that was signed and sealed by Mr. Richard V. Klar, P.G. (#259).

This report included the documentation as required by 30 TAC §§330.231 and 330.242, and is in accordance with the requirements of the permit modification issued on August 22, 2002, for the upgrade of the landfill to the meet the requirements of 40 CFR Part 258, Subtitle "D".

Please contact me at 512/239-6730 if you have any questions concerning this matter. When addressing written correspondence, please use Mail Code 124 (MC-124).

Sincerely,

Gale L. Baker, P.G.

Re: Groundwater Monitoring System Installation
City of El Paso McCombs Landfill - Permit No. MSW-729A
El Paso County, Texas

Dear Mr. Davis:

On behalf of the City of El Paso, Raba-Kistner Consultants (SW), Inc. (Raba-Kistner) is pleased to submit this letter report documenting the installation of the groundwater monitoring system at the above referenced facility. The groundwater monitoring system installation described herein was conducted in accordance with Site Development Plan (SDP) - Attachment 5 (Groundwater Characterization Report), applicable sections of the municipal solid waste (MSW) rules relating to monitor well construction specifications (30 TAC §330.242), and recent communications with the Texas Commission on Environmental Quality (TCEQ).

Groundwater Monitoring System Installation

As required by SDP - Attachment 5, three (3) groundwater monitor wells were installed at the McCombs Landfill. Drilling and monitor well installation activities were performed between July 17, 2003 and September 1, 2003 by a Texas-licensed driller, Mr. R.C. Corona (Texas Drillers License No. 4709M). Ms. Valerie Joosten, P.E. of Raba-Kistner monitored and logged the drilling and well installation activities. Figure 1 depicts the location of the three (3) groundwater monitor wells (designated as MW-1, MW-2 and MW-3) installed at the site.

The groundwater monitor wells were installed by mud rotary drilling methods using clean, treated city water and a bentonite additive, Quick-Gel®. Said drilling method and the use of the bentonite-based drilling additive were authorized by TCEQ correspondence dated June 20, 2003. As required by 30 TAC §330.242(a)(1)(B), a copy of the current chemical analysis of the city water used during drilling activities is included as Attachment 1.

The boreholes were advanced using a truck-mounted drilling rig equipped with a 10-inch outer diameter tri-cone drill bit. The drilling fluids and drilling cuttings were circulated from the borehole to a mud pit constructed adjacent to the borehole. Drilling cutting samples were collected from the recovered drilling fluid at approximately 10-ft intervals and at apparent changes in lithology. The samples were washed to remove the drilling mud from the samples and subsequently visually examined, classified and logged by the on-site Raba-Kistner

professional engineer in general accordance with standard field geotechnical sampling methods. The resulting boring logs depicting the subsurface strata encountered during drilling are presented as Attachment 2. As indicated on the boring logs, the subsurface strata encountered included intermittent and/or interbedded layers of clay, sand, gravel, cemented sands and caliche (calcareous soils).

The ambient levels of methane, hydrogen sulfide, oxygen, and combustible gas (lower explosive level) were continuously monitored during field activities using a Gastech GT Land Surveyor, which was calibrated with ambient air at the start of each day. In addition, a Photoionization Detector (PID) was used to continuously monitor ambient volatile organic compound (VOC) concentrations within the project area. The PID was calibrated with Zero Air and Isobutylene prior to the start of drilling operations. Methane, hydrogen sulfide, VOC or combustible gas concentrations were not detected during field drilling and sampling activities.

The boreholes for the three (3) groundwater monitor wells (i.e., MW-1, MW-2 and MW-3) were advanced to respective depths of 600, 505 and 520 feet below ground surface (ft bgs). The uppermost groundwater bearing zone was encountered during drilling at 456, 475 and 485 ft bgs (corresponding to elevations relative to mean sea level (msl) of approximately 3,611, 3,606 and 3,589 ft msl) for wells MW-1, MW-2 and MW-3, respectively.

Results of the previously conducted water well search for the landfill vicinity indicate that nearest water wells are located approximately 1,500 to 2,500 ft away and installed to approximate depths of 600 ft below ground surface. Based on review of available well construction details for nearest water wells, it is Raba-Kistner's understanding that screen lengths are on the order of 200 ft and likely tap multiple zones of saturation starting at approximately 400 ft below ground surface. On the basis of this data, MW-1 was advanced to 600 ft below ground surface in order to evaluate potential zones of saturation occurring between the 400 ft to 600 ft interval at the landfill site. On the basis of geologic conditions observed, Raba-Kistner contacted TCEQ MSW staff in order to confirm that landfill monitoring wells should be constructed to screen only the uppermost saturated interval identified. Based on discussions and email correspondence between R-K and TCEQ MSW staff, it was agreed that MW-1 should be completed in the following manner:

- Set top of well screen approximately 5 ft below the top of medium/coarse grained sand stratum identified at 456 ft bgs (i.e., 461 ft bgs [approx. 3,606 ft msl]).

- Set bottom of well screen to coincide with the base of the second underlying medium/coarse grained sand stratum at 473 ft bgs (approx. 3,594 ft msl).

- Install bentonite plug immediately above the well screen to extend a minimum of 5 ft into the suspected zone of saturation (i.e., 456 to 461 ft bgs).

Further, it was agreed that should similar subsurface geologic conditions be observed and the uppermost water bearing zones be encountered at similar depths during the installation of MW-2 and MW-3, then the screened intervals for said wells shall be constructed in a similar manner as for MW-1 (approximately 20 ft in length instead of using a longer screen). On the basis that similar subsurface geologic conditions were observed and the uppermost water

bearing zones were encountered at similar depths in MW-2 and MW-3, the respective screens were set at 478 to 498 ft bgs (approx. 3,603 to 3,583 ft msl) in MW-2 and 475 to 495 ft bgs (approx. 3,599 to 3,579 ft msl) in MW-3. The bentonite plug for the three (3) wells was constructed to extend approximately 8 ft from the top of the screen.

As indicated above, all three monitor wells were screened approximately 20 feet within the uppermost saturated interval encountered during drilling. In general, these intervals corresponded to medium/coarse-grained sand strata, which were in some cases separated by a thinly bedded clay or fine-grained sand stratum.

Well completion details can be found in the following attachments to this letter report:

- Attachment 2 - Boring Logs
- Attachment 3 - Monitor Well Data Sheets (TCEQ Form 10308)
- Attachment 4 - Texas Department of Licensing and Regulation (TDLR) Well Reports

The wells were constructed of 4-in. diameter Schedule 80 PVC casing and 0.01–in. slotted screen, with flush jointed sections and O-ring seals at each joint, and a bottom cap. The casing was centered within the borehole using stainless steel centralizers spaced at intervals of approximately 40 feet along the well solid casing length with additional centralizers at the top and bottom of the well screen.

The following monitor well components were installed around the well screen and casing (from bottom to top) using a tremie pipe:

- filter pack (10-20 silica sand) – extending from bottom of borehole to depths corresponding, at a minimum, to the top of screen
- annular seal (3/8-inch hydrated bentonite pellets) – extending approximately eight (8) feet above the top of filter pack or top of screen
- grout seal (Portland cement, bentonite, and water mixture) – extending from the top of the annular seal to ground surface.

The wells were completed with a vented PVC slip-on cap, 8-in. square by 5-ft long protective steel collar extending at least 1 ft bgs, a 5-ft long x 5-ft wide x 6-in. thick concrete pad constructed with wire mesh for structural stability, and a keyed padlock. Additionally, four 4-inch diameter by 5-ft long steel bollards were set in concrete approximately 2 ft offset from the corners of the concrete pad and extending to approximately 1.5 ft bgs. Figure 2 depicts a typical groundwater monitor well construction diagram, while Table 2 presents the associated monitor well construction data.

Upon completion of the installation of the three (3) groundwater monitor wells, the locations were surveyed by a Texas-licensed professional land surveyor. The elevations and coordinates are included on the TCEQ Monitor Well Data Sheets (Attachment 3) and the surveyor's certification (Attachment 5). The locations from which the well elevations were recorded were permanently marked in the concrete pad, top of casing, and top of protective collar.

Well Development

Upon the respective completion of well installation activities, each well was developed by bailing water from the well to remove drilling artifacts (i.e., drilling mud) and restore hydrogeological conditions of the water bearing zone surrounding the well screen. Subsequent to evacuating the drilling mud from the well casing, a minimum of three (3) well volumes were evacuated from each well. The actual volume of water removed was recorded on the well development forms included as Attachment 6. In addition, water pH, turbidity, conductivity, and temperature readings were also collected and recorded during well development. As indicated on the well development forms (Attachment 6), well development continued until the drilling fluids were adequately removed and effluent was clear. Water levels were gauged and recorded during and following well development. Based on the recorded water quality parameters, additional development is recommended.

Groundwater Levels and Flow Direction Data

The static groundwater level elevations were calculated based on the top of casing elevations and the gauged depth to groundwater at each of the three (3) installed wells and are indicated in Table 1 (Static Water Level Elevations) and on Figure 3 (Generalized Groundwater Flow Direction). As indicated on Table 1 and Figure 3, the static groundwater level elevations were calculated to be approximately 3,674, 3,684, and 3,685 ft msl for MW-1, MW-2, and MW-3, respectively. These static groundwater levels correspond to elevations approximately 68, 81 and 86 ft above the respective screened interval for wells MW-1, MW-2 and MW-3.

As indicated on Table 1, no water was encountered at MW-2 (i.e., dry well) during the gauging events conducted on October 30 and 31, 2003 due to an apparent obstruction encountered at approximately 430 feet below the top of casing (TOC) which prevented the measuring probe from advancing deeper into the well casing (total well depth is approx. 501 feet below TOC). However, subsequent gauging events did not detect the presence of said obstruction and the depth to water at MW-2 was measured to be approximately 400 feet below TOC (corresponding to an approximate elevation of 3684 ft msl).

On the basis of the groundwater level measurements conducted to date at the site, it appears that groundwater flow direction at this site is generally from to the south-southeast, with a localized west-to-east disturbance near the southern boundary of the site due to the apparent groundwater mounding measured at MW-2. The site-specific groundwater flow direction generally appears to correlate with the regional groundwater flow direction (also to the south-southeast) discussed in SDP-Attachment 5 for regional groundwater located within the Hueco Bolson aquifer. Figure 3 depicts the generalized groundwater flow direction at the site.

Localized disturbances in the groundwater flow direction may become apparent at subsequent monitoring event due to groundwater recharge/extraction activities at off-site water wells. However, the generalized site-specific groundwater flow direction at the site is expected to correlate with the regional groundwater flow direction to the south-southeast. Thus, as depicted on Figures 1 and 3, the point of compliance for this site is defined as the plane formed by drawing a line through monitor wells MW-1 and MW-2, and will be located along the

southern property boundary.

Qualified Groundwater Scientist Certification

The required certification by a qualified groundwater scientist is included herein as Attachment 7. The qualified groundwater scientist for this site is Richard V. Klar, P.G. of Raba-Kistner. Mr. Klar has a master's degree in Applied Geology (Hydrogeology emphasis) and over eight (8) years of experience in groundwater monitoring, hydrogeologic assessments, and monitoring well design and construction in support of corrective actions for leaking petroleum storage tanks, industrial/hazardous waste and closed municipal solid waste landfills, and permitting requirements for municipal solid waste facilities. Mr. Klar's corporate resume is also included in Attachment 7.

We trust that the information provided herein satisfies the groundwater monitoring system installation requirements for this site. If you have any questions or need additional information regarding this letter report, please do not hesitate to contact us.

Respectfully submitted,

TABLE 1 -- SUMMARY OF GROUNDWATER LEVEL DATA
City of El Paso McCombs Landfill -- Permit No. MSW-729A
El Paso County, Texas
R-K Project No. ASF02-045-00

Monitor Well	MW-1		MW-2		MW-3	
Installation Date	09-Aug-03		20-Aug-03		28-Aug-03	
Well Geodetic Coordinates (Latitude and Longitude[1])	N 31°59'00.63869" W 106°24'14.06849"		N 31°59'00.54479" W 106°24'25.57457"		N 31°59'43.41299" W 106°24'13.33502"	
Top of PVC Riser Elevation, ft msl	*4070.23*		*4083.89*		*4076.70*	
Surveyor's Pin Elevation, ft msl	*4067.72*		*4081.58*		*4074.11*	
Ground Surface Elevation, ft msl	*4067.35*		*4081.06*		*4073.68*	
Total Well Depth from Top of PVC, ft	475.88		500.83		498.02	
Well Bottom Elevation, ft msl	*3594.35*		*3583.06*		*3578.68*	
Measurement Date	**WATER LEVEL DEPTH (FT) / *ELEVATION (FT MSL)*** [2, 3]					
09/05/2003	396.15	*3674.08*	400.27	*3683.62*	397.71	*3678.99*
10/30/2003	396.04	*3674.19*	DRY[4]	----	391.79	*3684.91*
10/31/2003	396.05	*3674.18*	DRY[4]	----	391.85	*3684.85*
11/14/2003	396.29	*3673.94*	399.89	*3684.00*	391.52	*3685.18*
11/18/2003	396.03	*3674.20*	399.87	*3684.02*	391.25	*3685.45*

Notes:

1- Geodetic (latitude & longitude) coordinates were developed using Texas State Plane Coordinate System, central zone NAD833 (1993) datum. Elevations are based upon City of El Paso McCombs Landfil Datum.

2- Water level depths are indicated in feet (ft) measured from top of PVC riser

3- Top of PVC riser and water level elevations are indicated in feet referenced to mean sea level (ft msl)

4- An apparent obstruction was encountered at MW-2 at approximately 430 feet below the top of PVC riser. However, subsequent gauging events did not detect the presence of said obstruction.

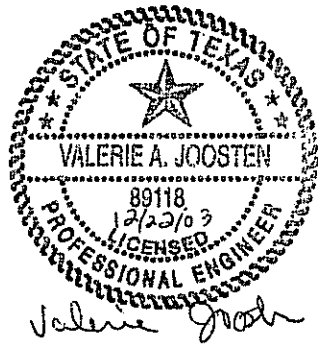

TABLE 2 -- MONITOR WELL CONSTRUCTION DATA
City of El Paso McCombs Landfill -- Permit No. MSW-729A
El Paso County, Texas
R-K Project No. ASF02-045-00

Notes:
- Geodetic (latitude & longitude) coordinates (Code A) were developed using Texas State Plane Coordinate System, central zone NAD833 (1993) datum. Elevations are based upon City of El Paso McCombs Landfil Datum.
- Surface elevations and coordinates (Codes A through E) were obtained from surveyor's vertical and horizontal control
- Codes F through L were measured for each monitor well using a field tape
- See **Figure 2** *Typical Monitor Well Construction Detail* for letter code (A-L) visualization
- Depths are indicated in feet (ft) measured from ground surface
- Elevations are indicated in feet referenced to mean sea level (ft msl)

Dimethylphthalate	<2.04

* This analyte is of known instability and quantitation should be considered approximate

** Phthalate contamination is unavoidable with this method's extraction technique. Consequently, phthalate levels cannot be accurately measured below 2.0 µg/L.

Analyte detected below the quantitation limit.

This analyte is known for extraction instability and quantitation should be considered approximate.

• Regulated compounds

Comments: The precision for hexachlorobenzene was outside QC limits for the LFB/LFB duplicate analysis with this extraction batch.

KEY TO SYMBOLS

Symbol Description

Strata symbols

Clay with Sand

Sand

Gravel

Clay

Cemented Sand

Clayey Sand

Misc. Symbols

Boring continues

Water table at boring completion

Soil Samplers

Sample Interval

Monitor Well Details

cement/bentonite grout with pipe

hydrated bentonite pellets with pipe

slotted pipe w/ sand

silica sand, no pipe (end plug)

cement/bentonite grout

end of well installation

KEY TO SYMBOLS

Notes:

DEFINITION OF DESCRIPTIVE TERMS

DENSITY OF GRANULAR SOILS	
SPT N Value	Relative Density
< 4	Very Loose
4 - 10	Loose
11 - 30	Med. Dense
31 - 50	Dense
50 - 80	Very Dense
> 80	Hard

CONSISTENCY OF COHESIVE SOILS	
SPT N Value	Consistency
< 2	Very Soft
2 - 4	Soft
5 - 8	Medium Stiff
9 - 15	Stiff
16 - 50	Very Stiff
50 - 80	Hard
> 80	Very Hard

DEGREE OF PLASTICITY

Non Plastic - Has no cohesion; will not roll into a thread.
Trace of Plasticity - Barely hold its shape when rolled into a thread.
Low Plasticity - Has sufficient cohesion to form a thread but will quickly rupture when deformed.
Med. Plasticity - Has considerable cohesion. Can be molded into a thread and will withstand considerable deformation without rupture.
High Plasticity - Can be kneaded like dough without trace of rupture.

MOISTURE DESCRIPTIONS

	Granular Soils	Cohesive Soils
Dry	No Apparent Moisture	No Apparent Moisture
Slightly Moist	< Than 3% by Weight	<Less Than Plastic Limit
Moist	3% to 9% by Weight	Approximatley Plastic Limit
Very Moist	>9% by Weight	> than PL but < than LL
Wet	Submerged or Saturated	Submerged or Saturated

ABBBREVATIONS

V. - Very Fl.- Fairly Sl. - Slightly Med. - Medium
Tr. - Trace < - Less than > - Greater Than PL - Plastic Limit
Mod. - Moderately

MONITOR WELL DATA SHEETS
TCEQ FORM 10308

Monitor Well Data Sheet

Permittee or Site Name: City of El Paso - McCombs Landfill
County: El Paso County
Date of Monitor Well Installation: 7/17/2003 - 8/9/2003
Monitor Well Latitude: 31 59'00.63869"Longitude: 106 24'14.06849"
Monitor Well Groundwater Gradient Position:
Upgradient _____ Downgradient X

MSW Permit No.: 729A
Monitor Well I.D. No.: MW-1
Date of Monitor Well
Development: 8/12/3003 - 8/13/2003
Monitor Well Driller
Name: R.C. Corona
License No.: 4709M

NOTES:

- Report all depths from Surface Elevation and all Elevations relative to Mean Sea Level (MSL), to nearest hundredth of a foot.
- Diameter of boring should be at least 4 inches larger than diameter of well casing.
- Use flush screw joint casing only, 2-inch diameter or larger, with o-rings or PTFE tape in joints (4-inch diameter recommend).
- Well development should continue until water is clear, and pH and conductivity are stable.

Geologist, Hydrologist, or Engineer Supervising Well Installation: Valerie A. Joosten, P.E.
Static Water Level Elevation (with respect to MSL) after Well Development: 3674.08 ft.
Name of Geologic Formation(s) in which Well is completed: Hueco Bolson

Type of Locking Device: Padlock Type of Casing Protection: 8-inch Square Steel Protective Collar
Concrete Surface Pad (with steel reinforcement) Dimensions: 6-in. x 5-ft. x 5-ft.

QUALIFIED GROUNDWATER SCIENTIST CERTIFICATION

RICHARD V. KLAR, P.G.

ENVIRONMENTAL GEOLOGIST

PRINCIPAL PRACTICE
Environmental Geology and Hydrogeology

EDUCATION
The University of Texas at San Antonio; M.S. Applied Geology (Hydrogeology), 1996
St. Mary's University, San Antonio, TX; B.S. Earth Sciences, 1992

PROFESSIONAL REGISTRATIONS
Professional Geologist: State of Texas Board of Geoscientists, No. 259
Professional Geologist: State of Nebraska Board of Geologists, No. G-0125
LPST Corrective Action Project Manager: TNRCC No. CAPM01395

PROFESSIONAL EXPERIENCE
Raba-Kistner Consultants, Inc., 1996 - Present
Center for Nuclear Waste Regulatory Analyses, SwRI, Graduate Scientist, 1992 - 1996
The U.T.S.A. Center for Water Research, Technical Staff II, 1995 - 1996

SELECTED PROJECT EXPERIENCE
Mr. Klar has over 8 years of diversified experience in geologic and hydrogeologic investigations in South Central Texas, New Mexico, and Nevada. Mr. Klar is currently responsible for implementing/overseeing site characterization and contamination assessment activities at municipal solid waste disposal sites in accordance with Federal and State regulations. Representative project experience includes surface and subsurface sampling of environmental media, landfill-gas and ground-water monitoring/recovery well design and installation, hydrogeologic investigations, earth electrical resistivity/conductivity surveys, investigation-derived wastes profiling and disposal, and associated data reduction/report preparation. Mr. Klar served as project geologist and prepared the Geology Report and Groundwater Characterization Report for the City of Seguin *(IESI Stagecoach Road Landfill)* permit modification. Additionally, Mr. Klar served as the project geologist for the preparation of closure and waste characterization plans for the *Hidalgo County Precinct 4 Landfill.*

Additional experience includes preparation of ground water monitoring reports and sampling and analyses plans *(Cities of Raymondville, Harlingen, and Seguin; and Hidalgo County)*, and the performance of earth electrical resistivity surveys to evaluate the potential for leachate migration as part of post-closure care activities *(City of Raymondville).* Other profesional experience includes modeling of ground water flow and contaminant transport; construction of 3-D hydrostratigraphic models; acquisition and analysis of ground magnetic, electromagnetic, and resistivity data; and development of GIS databases in support of site characterization activities for the U.S. DOE licensing of a proposed high level nuclear waste repository at Yucca Mountain, Nevada.

PROFESSIONAL MEMEBERSHIPS
South Texas Geological Society, Association of Engineering Geologists, National Ground Water Association

§330.230(c)(2) **Qualified Groundwater Scientist Certification**

I, Richard V. Klar, P.G., certify that the City of El Paso - McCombs Landfill, MSW Permit No. 729A, is in compliance with the groundwater monitoring requirements specified in 30 TAC §§330.231-330.235 (relating to Groundwater Monitoring and Corrective Action).

RE: Attachment 5 - Groundwater Characterization Report
McCombs Landfill
MSW Permit No. 729A
Class I Permit Modification
El Paso County, Texas

Dear Mr. Holderread:

Per the request of our client, The City of El Paso, Raba-Kistner Consultants (SW), Inc. is resubmitting to the Texas Natural Resource Conservation Commission (TNRCC) the document listed below in partial compliance with 30 TAC 330.56(e) as it pertains to the McCombs Landfill Permit Modification Application. Thus, Attachment 5 consists of a copy of Sections 1.0 through 3.0 (and applicable figures) of the following document, which is included as an Appendix:

- Appendix Att5-A: May 12, 1995 Groundwater Sampling and Analysis Plan (partial sections)

This document is being submitted in partial compliance with the TNRCC first technical review letter dated June 21, 2002.

Upon approval of this permit modification, the City of El Paso will install the groundwater monitoring system described in this application. Upon installation of said system, the City of El Paso will submit a statement of certification for the well installation as required under 30 TAC §330.230(c)(2), monitoring well reporting forms (TNRCC-10308), and a figure complying with the requirements of 30 TAC §330.56(e)(3).

Respectfully submitted,

RABA-KISTNER CONSULTANTS (SW), INC.

1. INTRODUCTION

AGRA Earth & Environmental, Inc. (AEE) has prepared this Groundwater Sampling and Analysis Plan (GWSAP) as part of the scope of services to be performed during the implementation of a groundwater monitoring program at the McCombs Landfill in El Paso County, Texas. This sampling plan is designed to provide details of field activities and documentation to be implemented. This plan replaces our October, 1993 version of the GWSAP, however, the Site Characterization portion of that document has not changed and should be used in conjunction with this plan.

Included in this document are:

- Details of borings to be drilled to evaluate the hydrogeologic and geotechnical properties of the soil.
- Installation details for monitor wells which will be placed to determine the depth to and quality of groundwater beneath and adjacent to the site.
- Details describing groundwater sampling and field analytical testing.
- Guidelines for preservation, transportation and analysis of groundwater samples.
- Guidelines for handling, temporary storage and disposal of materials suspected to be hazardous that will be generated during implementation.

It is understood that the details of the field exploration program provided herein are based on the information available at the time this document was prepared. AEE may modify these specifications based on conditions encountered in the field, pending review and approval by the City of El Paso (City) and the Texas Natural Resource Conservation Commission (TNRCC).

2. OBJECTIVES

The principal objective of this study is to formulate and implement a groundwater monitoring plan at the McCombs Landfill in order to comply with regulatory requirements set forth by Chapter 330 of the Texas Administrative Code (TAC) pertaining to Solid Waste Disposal. To accomplish this, a two-phased approach was adopted.

Phase I:

The primary objective of Phase I is to review available geologic, hydrogeologic, and geotechnical information on the site. This information along with climatological data and site specific landfilling operational data was processed utilizing the HELP model. HELP is a computer program used to model leachate production and physical attenuation at landfill sites. Based on results of the above studies, the location and number of monitor wells will be determined. Details regarding placement, development and sampling of wells are provided in this GWSAP. Phase I will be complete with the submission of the GWSAP to the TNRCC and negotiating acceptance.

Phase II:

Upon approval of the GWSAP, subsurface drilling and monitor well installation will commence in accordance with guidelines specified in this document. Groundwater sample collection, preservation, transportation, and chain-of-custody documentation will be completed as discussed in the GWSAP.

Subsequent phases of the project will include implementation of Detection and Assessment Monitoring programs in accordance with TAC §330.234 & §330.235. If required, an assessment of corrective measures will be implemented in accordance with TAC §330.236.

3. SITE BACKGROUND

A detailed description of the site history and operations is included in the Site Characterization document submitted earlier, and summarized herein for completeness.

According to City personnel, landfilling operations began at the McCombs Landfill in 1960. The landfill was initially permitted by the Texas Department of Health in August, 1976. The Permit was modified in May, 1984 to cover a total area of 327 acres.

The landfill is located approximately 20 miles northeast of downtown El Paso, in Section 6, Block 80, Township 1, Texas and Pacific Surveys, in El Paso County (see Figure 1). The landfill permit area encompasses approximately 327 acres, although only a portion is developed as a landfill at present. The landfill is situated on deposits of the Hueco Bolson. The Hueco Bolson sediments have been divided into three rock stratigraphic units, the Fort Hancock and the Camp Rice Formations of Pleistocene age and recent alluvial and eolian deposits developed on them. The McCombs landfill is probably directly underlain by Pleistocene sediments of the Camp Rice Formation. These deposits primarily consist of clay, sand and gravel, with some caliche.

Based on a review of published data, depth to groundwater at the landfill site is estimated to be between 370 to 390 feet, however, some variation in depth to groundwater is expected. The groundwater flow direction is generally assumed to be primarily to the south and southeast, however, pumping in the area may locally affect groundwater gradients both now and in the future.

1 INTRODUCTION AND PURPOSE

The Ground Water Sampling and Analysis Plan (GWSAP) presented herein was prepared to describe procedures and methodologies associated with the collection, handling and laboratory testing of ground water samples for the City of El Paso McCombs Landfill (MSW Permit No. 729B). The purpose of the GWSAP is to define site-specific standards and practices for ground water sampling and analysis within the context of a stand-alone document that provides a concise set of instructions to sampling and analytical personnel conducting a ground water sampling program. This GWSAP has been updated to comply with 30 TAC 330 Subchapter J: Groundwater Monitoring and Corrective Action (effective March 27, 2006). Once approved by the Texas Commission on Environmental Quality (TCEQ), this GWSAP will replace the previous GWSAP within the Site Development Plan for the City of El Paso McCombs Landfill.

The ground water sampling program will be conducted in accordance with the procedures established herein. Although the GWSAP addresses the collection, handling, storage, and treatment of the samples (both in the field and at the testing laboratory), the contract laboratory that actually performs the analyses of ground water samples will submit a Laboratory Standard Operating Procedures (LSOP) document to the TCEQ prior to the implementation of the sampling program. The LSOP will describe specific laboratory protocols used to provide data of stated quality with a stated probability of being correct including all procedures to handle and analyze samples from receipt until results are officially reported.

2 MONITORING POINT INSPECTION

The location of each monitoring point (hereinafter also referred to as "monitoring well" or "well") will be initially verified using a current site map to confirm that appropriate monitoring wells are identified for sampling. The unique well identification numbers will be verified with the identification markers shown on well installations and recorded on the field data sheet (or an equivalent form) (depicted as ***Figure Att11-1***). Field data sheets for each monitoring well will accompany field personnel performing ground water monitoring to the subject landfill during monitoring events.

Prior to the commencement of monitoring well gauging or purging activities, the condition of site wells will be visually inspected. The well casing and concrete pads will be checked for the presence of cracks or fissures that could compromise the integrity of the surface completion. Each well will be additionally inspected for damage due to vandalism, animals or insects, and/or heavy equipment operations. Descriptions of apparent well damage or conditions conducive to the transmission of surface runoff along monitoring well installations will be noted in the *"Remarks"* section of the field data sheet. If any problems are discovered, they will be repaired/replaced as soon as practicable.

3 GAS MONITORING/WATER LEVEL MEASUREMENTS

The presence of explosive gases within the well casing at respective monitoring well locations will be evaluated utilizing a properly calibrated landfill gas monitor. Measurements will consist of gas temperature, pressure, and concentration. Well casings will be screened during each monitoring event to verify that the concentration of methane gas does not exceed 25 percent of the lower explosive limit (LEL) for methane. In the event that methane is detected at concentrations that exceed 25 percent of the LEL, steps will be immediately taken to ensure the protection of human health and safety pursuant to the contingencies described in *30 TAC §330.371*. A record of field methane measurements will be recorded on the field data sheet-(or an equivalent form).

Prior to purging site monitoring wells, the depth to water and total well depth measurements will be gauged at each well location from a permanent, clearly marked reference point on the well (i.e., top of casing [TOC]). The water level measurements will be recorded to the nearest hundredth of a foot utilizing an electronic water-level indicator (e-line). To ascertain that potential contaminants are not introduced to the monitoring wells as the result of gauging activities, the e-line probe and measurement tape will be decontaminated before and after each use. Decontamination procedures are further described in **Section 4.0: Well Purging** of this GWSAP. The decontamination fluids will be containerized pending the results of ground water sampling and analyses.

4 WELL PURGING

In order to obtain representative ground water samples, the monitoring wells will be purged to remove water from the well casing that may not be chemically representative of the formation ground water. Well purging will be accomplished utilizing either a properly decontaminated submersible pump or a dedicated Teflon® or polyethylene bailer. In the event that a pump is used to purge monitoring wells, purging equipment including pump, tubing, and connectors will be decontaminated according to the following procedure:

1) Conduct an initial wash using a mild solution containing a biodegradable, phosphate-free detergent such as Alconox®;

2) Conduct a second wash utilizing clean drinking-grade water; and

3) Conduct a final rinse using reagent-grade water obtained from the analytical laboratory.

In order to prevent cross-contamination of purging equipment by field personnel, clean, disposable, powder-free, nitrile or latex gloves will be used when handling the decontaminated purging equipment. Prior to purging and sampling, clean, disposable plastic sheeting will be placed around respective wells in order to prevent clean equipment from coming into contact with the ground.

During purging, a minimum of three (3) well casing volumes of ground water will be removed from respective monitoring wells. As indicated on the attached field data sheet (please see ***Figure Att11-1***), the volume of water to be removed at each well location will be calculated based on the respective height of the water column in the monitoring well and the well casing diameter. If sufficient ground water is available, purging will continue until field parameters including pH, temperature, turbidity, and conductivity have stabilized and the ground water is clear. A description of measurement protocols for field parameters is provided in **Section 6.2: Field Measurements** of this GWSAP. Parameter stabilization is defined as:

- Specific Conductivity = ± 10% for three (3) consecutive measurements;
- pH = ± 0.2 standard pH units for three (3) consecutive measurements;
- Temperature = ± 10% for three (3) consecutive measurements;
- Turbidity = ± 10% for three (3) consecutive measurements unless under 10 NTU (all values under 10 NTU are considered stable).

In the event that monitoring wells recharge very slowly, wells will be purged to dryness in order to remove stagnant water from well casings. Wells will be allowed sufficient time (maximum of 72 hours) to recover such that ground water samples can be collected. Whenever possible, the ground water level shall be allowed to recover to within 90 percent of the original water level measurement prior to sampling. In the event that sufficient well volume for sampling is not available within 72 hours of purging, it is understood that TCEQ may require a longer duration for recovery of sufficient sampling volume or the adoption of an alternate strategy to obtain samples from low-yield wells. As further described in **Section 6.1** of this GWSAP, site conditions may facilitate the application of Low-Flow Purging and Sampling Techniques as an alternative to conventional well purging and sampling methods described above.

All data collected prior to sampling will be recorded on the field data sheet (or an equivalent form) and will include the following, at a minimum:

- initial depth to water,
- measured depth to the bottom of the well,
- height of the water column inside the well,
- well casing volume,
- purging rate,
- time spent purging the well,
- water volume purged from the well,
- a record of pH, conductivity, temperature, turbidity readings, and
- information resulting form the well inspection and other pertinent information.

Ground water removed from site monitoring wells during purging activities will be stored in labeled 55-gallon drums or similar containers. The ground water containers will be temporarily stored on site until analytical results are received from the contract laboratory. If the report of laboratory analyses indicates that the concentrations of contaminants do not exceed levels of concern as determined by TCEQ, the water will be applied to the unsaturated soil on-site. In the event that analytical results indicate concentrations of contaminants that are above levels of concern or classified as hazardous by TCEQ, the water will be properly disposed of at a wastewater treatment facility, hazardous waste facility, or other authorized facility in accordance with applicable TCEQ and federal regulations.

5 TIMING AND ORDER OF SAMPLING

In association with each monitoring event, ground water sampling will be accomplished as soon as practicable subsequent to the completion of purging activities to avoid temporal variations in water levels and water chemistry. When possible, sampling activities will be conducted within twenty-four (24) hours of well purging. As described in **Section 4.0: Well Purging** of this GWSAP, a maximum of 72 hours will be allowed subsequent to purging in the event that monitoring wells recharge slowly and sufficient water volume is not available for sampling at a lesser duration. In the event that sufficient well volume for sampling is not available within 72 hours of purging, it is understood that TCEQ may require a longer duration for recovery of sufficient sampling volume or the adoption of an alternate strategy to obtain samples from low-yield wells. In general, the time interval between purging and sampling activities will be kept to a minimum, particularly when the analysis of volatile organic compounds (VOCs) is required.

In an effort to avoid cross-contamination of samples between monitoring wells during respective monitoring events, sampling will commence at the monitoring well which is known to be the least contaminated and conclude with the most contaminated well. In the absence of contamination data for newly installed monitoring wells during initial background monitoring events, the order of sampling will be from the well with the highest water-level elevation to the well with the lowest elevation (upgradient to downgradient) for each group of wells completed within a discrete water bearing interval.

6 SAMPLE COLLECTION, PRESERVATION, AND SHIPMENT

In an effort to maximize the validity of ground water samples and protect sample integrity, the following procedures for sample collection, preservation, and shipment will be implemented. The methods and procedures described herein will be consistently applied at site monitoring wells and throughout subsequent ground water monitoring events.

6.1 Sample Collection

Ground water samples will be collected at each well location utilizing a pump or a new, clean, disposable bailer suspended from new, clean nylon string. In order to minimize turbulence and aeration and associated potential volatilization of organic compounds during sampling, adjustable flow rate pumps will be used or bailers will be equipped with a bottom-emptying device allowing water to be discharged slowly from the bottom directly into sample containers. Field personnel will wear new, clean, disposable nitrile or latex gloves throughout the duration of sampling at each well location. Soiled sample bottles, bailers, nylon string, and filtration media will not be reused at subsequent well sampling locations.

In the event that ground water samples are collected immediately subsequent to purging activities (6 to 12 hours), it is not anticipated that ground water present at the top of the water column will be oxidized to an extent that could potentially affect the collection of representative ground water samples. In the event that sufficient sample volume recharges into monitoring wells and sampling is conducted within 24 hours of purging the first portion of collected water (approximately 2 liters [i.e., 0.5 gallons]) will be discarded to eliminate potentially oxidized water prior to filling sample containers. In the event that site wells recharge slowly and must be sampled more than 24 hours after purging, a lesser volume may be initially discarded in order to preserve sufficient sampling volume for analytical chemistry assignments.

In the event that site wells recharge slowly, low-flow purging and sampling techniques in accordance with guidance contained in EPA publication *EPA/540/S-95/504, Low-Flow (Minimal Drawdown) Ground Water Sampling Procedures (April 1996)*, may be adopted as an alternative to conventional purging and sampling methods described in **Section 4.0** of this GWSAP. If low-flow procedures are to be used, a demonstration of the suitability of low-flow procedures will be prepared and submitted to TCEQ for review and acceptance prior to implementation.

6.2 Field Measurements

An unfiltered portion of the ground water will be poured into a clean container for field measurement of temperature, specific conductance, and pH. The temperature readings will be measured immediately upon collection. Subsequently, measurements of specific conductance

will be accomplished to avoid any effect on the sample from salts on the pH probe. The specific conductance readings will be followed by the pH measurements. In addition to recording ground water parameter measurements, observations regarding the ground water color, odor, foaming, presence of more than one phase of liquid, and turbidity will be recorded on the field data sheet (or an equivalent form).

Equipment utilized for the field measurements will be calibrated each day that the equipment is used in the field. Copies of the daily calibration logs will be kept on file. Provisions will be made for backup equipment in the event of a primary equipment failure during the course of a monitoring event.

6.3 Sample Containers

The volume of samples and the types of sample containers depends on the parameters to be analyzed during respective monitoring events and will be consistent with EPA guidance. Sampling, preservation, and storage procedures for potential ground water monitoring parameters are presented in ***Table Att11-1***.

Sample containers will be filled in the following order according to volatilization sensitivity:

1. **VOCs** (volatile organic compounds)
2. **SVOCs** (semi-volatile organic compounds) (if collected)
3. **Metals**
4. **Other Inorganic Parameters** (if collected)

Although volatilization is of primary concern during VOC sampling, designated VOC vials will additionally be sampled from the same bailer or directly from the pump in order to prevent inhomogeneity in the samples resulting from the presence of suspended sediments. Inhomogeneity of samples owing to the presence of suspended sediments is additionally of concern when collecting samples with a bailer to the extent that VOCs adsorbed to sediment particles can influence measured concentrations in ground water. However, as wells were or will be properly designed, constructed, and installed, it is not anticipated that appreciable suspended sediments will be encountered during sampling activities.

The contract analytical laboratory will supply appropriate pre-preserved sampling containers, labeled by analyte, prior to the mobilization of sampling personnel to the subject landfill. Sample containers will be subsequently labeled in the field for identification purposes and will include the following information at a minimum: site identification, monitoring well number, date and time of sample collection, type of preservatives used, analyses to be performed (in accordance with laboratory designation), and the name of the sampler. Information will be written on laboratory-supplied sample labels using indelible ink and covered with transparent tape to protect written data.

6.4 Types of Sample Containers

As referenced in ***Table Att11-1*** of this GWSAP, the following sample containers and protocols will be utilized during ground water monitoring at the subject landfill.

- VOCs: Two (2) 40-ml glass vials with special caps containing Teflon septa will be used per analysis. Containers will be pre-preserved with HCL by the contract laboratory. Prior to filling, the septum of each vial will be placed with the Teflon side toward the sample. During filling, water will be allowed to stream down the inner wall of the vial to minimize formation of air bubbles. The vials will be slightly overfilled in order to create a positive meniscus. Upon completion of filling, caps will be carefully screwed on to avoid leaving any airspace within the vials. In the event that an air bubble forms in a vial subsequent to capping, an additional separate 40-ml sample will be collected.

- SVOCs (if collected): One (1) amber one-liter glass bottle with Teflon-lined cap will be used per analysis. Containers will be completely filled and capped.

- Metals: One (1) one-liter polyethylene bottle, pre-preserved with HNO_3 by the contract laboratory, will be used per analyses for total metals. Containers will be completely filled and capped. Groundwater samples for constituents in Appendices I and II to Title 40 Code of Federal Regulations, Part 258 will not be filtered in the field or the laboratory prior to analysis.

- Other Inorganic Parameters (if collected): Depending on the specific parameters to be analyzed, one or more glass/plastic one-liter containers will be used per analyses of the suite of inorganic parameters including those listed on ***Table Att11-1***. With the exception of ammonia (in the event that it is assigned for analysis), preservatives will not be used on samples collected for other inorganic parameter analyses.

6.5 Sample Preservation and Holding Times

Sample preservation is intended to 1) retard biological action, 2) retard hydrolysis, and 3) reduce sorption effects. Preservation methods are generally limited to pH control, chemical addition, refrigeration, and protection from light. Specific preservation methods for analytes that may be assigned in association with ground water monitoring at the subject landfill are presented in ***Table Att11-1***.

Specific sample volumes required for each analysis and associated sample holding times will be reviewed with the contract analytical laboratory prior to sampling. In general, these requirements will be consistent with those presented in ***Table Att11-1***.

6.6 Sample Storage and Transport

In accordance with preservation requirements presented in ***Table Att11-1***, sample containers will be placed into a clean, insulated cooler and kept on ice following sample collection. Adequate

ice will be kept on the samples to maintain a maximum temperature of 4°C (39.2°F) during transport to the contract analytical laboratory. The samples will be kept in the sampler's possession at all times, unless samples are shipped to the laboratory by a courier, and will be submitted to the laboratory via proper chain-of-custody protocol within forty-eight (48) hours of sampling.

6.7 Chain-of-Custody Documentation

Appropriate Chain-of-Custody (COC) procedures will be implemented to protect sample integrity and to provide technically and legally defensible ground water quality data. At any time that a ground water monitoring event is conducted, a COC form will be completed, placed in a sealable plastic bag, and placed in the cooler with the samples collected. The completed COC form will accompany the samples at every step from the field to the laboratory and will be signed by each party handling the samples, from sampler, through transporter to the laboratory to document the possession of the samples at all times. An example COC form is provided as ***Figure Att11-2*** of this GWSAP.

In the event that samples are sent by mail to the contract analytical laboratory, packages containing samples will be certified with return receipt requested to document shipment. If the samples are shipped via overnight courier, the bill of lading will be retained to document shipment. Copies of the return receipt/bill of lading will be subsequently attached to the COC at the completion of each stage of shipment.

6.8 Documentation of Sampling

As described in ***Sections 2.0 though 4.0*** of this GWSAP, information related to a sampling event will be recorded on the field data sheet (or an equivalent form) (***Figure Att11-1***). All entries will be legible and made in indelible black ink. Entry errors will be crossed out with a single line, dated, and initialed by the person making the corrections. Sufficient information including sample location, date, time, weather, and affiliation of field personnel, field measurements including the numerical values and units, the integrity of the well, methane gas measurements, etc. will be recorded on field data sheets such that the monitoring event can be reconstructed without relying on the sampler's memory. Completed field data sheets will be maintained in project files as a permanent record of ground water monitoring activities and submitted to TCEQ along with the standard ground water sampling report forms (TCEQ-0312) for respective sampling events.

Pursuant to directives issued by the MSW Permits Section effective February 1, 2001, ground water sampling reports will be submitted in electronic format, in addition to paper copies. Electronic versions of the ground water sampling reports will be submitted in accordance with procedures established by TCEQ in place at the time of sampling.

7 ANALYTICAL PARAMETERS

The detection monitoring constituents at the facility will be as specified in 30 TAC §330.419 and 40 Code of Federal Regulations (CFR) 258 Appendix I (see ***Table Att11-2*** of this GWSAP). The practical quantitation limit (PQL) for each constituent will be the lowest concentration level that can be reliably achieved within specified limits of precision and accuracy during routine laboratory operating conditions that are available to the facility, per 30 TAC §330. 405(f)(5).

The practical quantitation limit (PQL) is defined as the lowest concentration reliably achieved within specified limits of precision and accuracy during routine laboratory operating conditions and is analogous to the limit of quantitation (LOQ) definition in the most recent available NELAC Standard (National Environmental Laboratory Accreditation Conference). The PQL is method, instrument, and analyte specific and may be updated as more data becomes available. The PQL must be below the groundwater protection standard established for that analyte as defined by 30 Texas Administrative Code Section §330.409(h) unless approved otherwise by the TCEQ. The precision and accuracy of the PQL shall be initially determined from the PQLs reported over the course of a minimum of eight groundwater monitoring events.

The results obtained from these events shall be used to demonstrate that the PQLs meet the specified precision and accuracy as shown in the table below. The PQL will be supported by analysis of a PQL check sample, which is a laboratory reagent grade sample matrix spiked with chemicals of concern at concentrations equal to or less than the PQL. At a minimum, a PQL check sample will be performed quarterly during the calendar year to demonstrate that the PQL continues to meet the specified limits for precision and accuracy as defined in the table below.

QC Specification Limits for the PQL and Lower Limit of Quantitation Check Samples

COC	Precision (% RSD)	Accuracy (% Recovery)
Metals	10	70-130
Volatiles	20	50-150
Semi-Volatiles	30	50-150

For analytes that the established PQL cannot meet the precision and accuracy requirements in the table above, the owner/operator will ensure the laboratory will submit sufficient documentation and information to the TCEQ for alternate precision and accuracy limits on a case by case basis. Non-detected results will be reported as less than the established PQL limit that meets these precision and accuracy requirements.

It is not considered likely that metals including antimony, beryllium, thallium, and vanadium will be present in ground water present beneath a municipal solid waste landfill (MSWLF). After the completion of the background monitoring program, it is anticipated that the omission of some heavy metals will be proposed to TCEQ. Changes and/or modifications to the list of analytes provided in ***Table Att11-2***, if necessary, will be submitted to TCEQ in the form of a permit modification request.

8 ANALYTICAL METHODS

The ground water monitoring program described herein will include the application of appropriate analytical methods in order to accurately measure concentrations of hazardous constituents or other monitoring parameters that may be present in the ground water samples. EPA-approved methods will be utilized for analyses of ground water samples obtained at the subject landfill in accordance with procedures described in the following published references:

- EPA 600/4-79-020, *Methods for Chemical Analysis of Water and Wastes*, March 1983
- EPA SW-846, *Test Methods for Evaluating Solid Waste*, Third Edition, November 1986, and its updates.
- *Standard Methods for the Examination of Water and Wastewater*, 18th Edition, 1992.

As stipulated previously in ***Section 1.0: Introduction and Purpose*** of this GWSAP, the contract laboratory that performs analyses of ground water samples will submit a LSOP document to TCEQ prior to the implementation of the sampling program described herein. The LSOP will describe specific laboratory protocols used to provide data of stated quality with a stated probability of being correct including all procedures to handle and analyze samples from receipt until results are officially reported.

9 LABORATORY PROCEDURES AND PERFORMANCE STANDARDS

The facility will submit laboratory data and analyses prepared by a TCEQ-accredited environmental testing laboratory and in accordance with acceptable accreditation standards (e.g. NELAC).

The owner or operator shall review all analytical data submitted under the requirements of this permit to ensure compliance with data quality objectives, prior to submittal of the data to the TCEQ for review. This data review will include examination of the quality control results and other supporting data, including any data review by the laboratory. This data review will also identify any potential impacts such as bias on the quality of the data using qualifiers in the test reports tied to explanations in footnotes and in any laboratory case narrative which is required.

It is the responsibility of the owner or operator to ensure that the laboratory documents and reports all problems and anomalies observed that are associated with the analysis. If the analysis of the data indicates that it failed to meet the quality control goals for the laboratory's analytical data analysis program, it does not necessarily mean that the data is unusable. The owner or operator may still report to the TCEQ the analytical data but will also report any and all problems and corrective action that the laboratory identified during the analysis.

A Laboratory Case Narrative (LCN) report for all problems and anomalies observed will be submitted by the owner and/or operator. The LCN will report the following information:

1. State the exact number of samples, testing parameters, and sample matrix.
2. The name of the laboratory involved in the analysis. If more than one laboratory is used, all laboratories shall be identified in the case narrative.
3. State the test objective regarding samples.
4. Explain each failed precision and accuracy measurement determined to be outside of the laboratory and/or method control limits.
5. Explain if the effect of the failed precision and accuracy measurements on the results induces a positive or negative bias.
6. Identify and explain problems associated with the sample results, along with the limitations these problems have on data usability.
7. A statement on the estimated uncertainty of analytical results of the samples when appropriate and/or when requested.
8. A statement of compliance and/or noncompliance with the requirements and specifications. Exceedence of holding times and identification of matrix interferences will be identified. Dilutions shall be identified and if dilutions are necessary, they will be done to the smallest

dilution possible to effectively minimize matrix interferences and bring the sample into control for analysis.

9. Identify any and all applicable quality assurance and quality control samples that will require special attention by the reviewer.
10. A statement on the quality control of the analytical method of the permit and the analytical recoveries information shall be provided when appropriate and/or when requested.

In addition to the LCN, the following information will be submitted for all analytical data:

1. A Table identifying the field sample name with the sample identification in the laboratory report.
2. Chain of custody will be provided.
3. Analytical Report that documents the results and methods for each sample and analyte to be included for every analytical testing event. These test reports will document the reporting limit/method detection limit the laboratory used. The reporting limit for each analyte will be less than the maximum contaminant level (MCL) or as low as practically feasible per 30 TAC 330.263(b) for each of the analytes. In accordance with Appendix B of 40 CFR Part 136, the method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero and is determined from analysis of a sample in a given matrix containing the analyte.
4. A release statement will be submitted from the laboratory. This statement will state "I am responsible for the release of this laboratory data package. This data package has been reviewed by the laboratory and is complete and technically compliant with the requirements of the methods used, except where noted by the laboratory in the attached exception reports. By my signature below, I affirm to the best of my knowledge, all problems/anomalies, observed by the laboratory as having the potential to affect the quality of the data, have been identified by the laboratory in the Laboratory Review Checklist, and no information or data have been knowingly withheld that would affect the quality of the data."
    a. If it is an in-house laboratory, it will have the following statement: This laboratory is an in-house laboratory controlled by the person responding to rule. The official signing the cover page of the rule-required report (for example, the APAR) in which these data are used is responsible for releasing this data package and is by signature affirming the above release statement is true.
5. If the data is from soil and/or sediment samples, it will be reported on a dry weight basis with the percent solids and the percent moisture reported so that any back calculations of the wet analysis may be preformed.
6. Include a Laboratory checklist in the Laboratory Data Package. An example of the Laboratory checklist is provided in Appendix 1. The permittee may amend the checklist as long as it includes the information found in Appendix 1. For every response of "No, NA, or NR" that is reported on the checklist, the permittee will ensure the laboratory provides a detailed description of the "exception report" in the summary of the LCN. The phrase "exception report" in the checklist is meant to clue the owner/operator to include the

exceptions and any potential bias in the data will be in the LCN. The permittee will ask the laboratory to use the checklist and do an equivalent of an EPA Level 3 review regarding quality control analysis.

Please note the Laboratory Checklist provided in Appendix 1 is amended from the Texas Risk Reduction Prevention (TRRP) Appendix A checklist. TRRP standards and requirements for quality apply in a limited capacity only. TRRP requires an EPA Level 4 review of the data for analysis. The analytical results, quality control information, and a laboratory case narrative are essentially required by an EPA Level 3 review. Hence, the TRRP standards for an EPA Level 3 review apply; whereas, the standards of an EPA Level 4 review do not apply. The laboratory checklist is intended to aid the permittee in ensuring the laboratory did a quality control analysis and to alert one of any potential problems, bias, or anomalies during the analysis of the sample. The analytical report, LCN, and the checklist are to be included along with the TCEQ-0312 forms for all monitoring events for groundwater.

10 BACKGROUND SAMPLES

"Background" refers to the chemical characteristics of ground water comprising a data set to which the chemical characteristics of the current samples are compared to determine if the current samples show statistically significant increase (SSIs) in those characteristics. Background water quality will be established for the metals and VOCs listed in ***Table Att11-2*** of this GWSAP pursuant to 30 TAC 330.419 and 40 Code of Federal Regulations (CFR) 258 Appendix I. Additionally, water quality parameters may be sampled and analyzed at the discretion of the facility operator, but that the results will not be subject to statistical evaluation.

The spacing of background monitoring events will be adequate to facilitate the hydraulic and chemical stabilization of ground water such that consecutive samples are statistically independent. It is initially proposed that background monitoring events be conducted quarterly over the duration of two years in order to incorporate seasonal variations in water chemistry into the background data set. In the event results of initial background monitoring indicate that a quarterly frequency will not likely produce statistically independent samples based upon the calculated ground water gradient, an alternate background monitoring frequency will be proposed to TCEQ as a permit modification. The specific methodology for determining ground water sampling frequency is further discussed in ***Section 14.2: Independent Samples*** of this GWSAP.

Background samples will be collected from the site monitoring wells included as part of the ground water monitoring system. After background analyses have been completed, data will be treated statistically and background concentrations established for each parameter.

Per 30 TAC §330.407 (a)(1), semi-annual data may be incorporated into the background data set at a maximum frequency of once every two years. New data will be evaluated for any significant trends and potential outliers (or by an approved alternative method that provides equivalent or better performance). Appropriate data will then be incorporated into background with prior TCEQ approval.

A general discussion and flow chart describing the application of statistical methods to background and detection monitoring are presented in ***Section 14.0: Statistical Methods*** and ***Figure Att11-3***, respectively. In accordance with 30 TAC §330.407(a)(1), upon completion of background monitoring and during background updates, the owner or operator will evaluate the background data to ensure that the data are representative of background groundwater constituent concentrations unaffected by waste management activities or other sources of contamination, and that the evaluation will be documented in a report and submitted to the executive director before the next subsequent groundwater monitoring event following the updated (or initial) background period.

11 DETECTION MONITORING

Subsequent to the completion of background monitoring, detection monitoring will be conducted on a semi-annual basis (i.e., once every six months). The first detection monitoring event will occur approximately six (6) months after completion of background sampling pending the reduction of background sampling data. In the event that statistical analysis of the groundwater analytical results indicates an initial statistically significant increase (SSI) from background of any tested constituent at any on-site well, a notice in writing to the Executive Director and any local pollution agency with jurisdiction that has requested to be notified will be submitted within fourteen (14) days of the determination of the SSI (30 TAC §330.407(b)). In the event that a SSI occurs in ground water chemistry data, or if deemed necessary by TCEQ, and alternate monitoring frequency may be adopted. It is understood that the adoption of an alternate monitoring frequency will require TCEQ concurrence. If warranted, an alternate detection monitoring frequency will be proposed as a permit modification request.

Site wells comprising the ground water monitoring network will be sampled during each detection monitoring event in accordance with the methodologies and procedures described herein. As previously stipulated, it is anticipated that the omission of some heavy metals will be proposed to TCEQ following the completion of the background monitoring program. If warranted, proposed changes and/or modifications to the list of analytes provided in ***Table Att11-2*** will be submitted to TCEQ as a permit modification request.

12 ASSESSMENT MONITORING

The occurrence of a confirmed SSI from background for a specific detection monitoring constituent (see ***Table Att11-2***) during a sampling event will result in the implementation of assessment monitoring unless it can be adequately demonstrated that the SSI is due to a source other than the landfill, or that it resulted from error in sampling, analyses, statistical evaluation, or natural variation in ground water quality. For purposes of this GWSAP, an apparent SSI is defined as an initial statistical exceedence that has not been verified. It is understood that verification re-sampling events are essential to a satisfactory demonstration to avoid assessment monitoring. In the event that an apparent SSI is determined as the result of a detection monitoring event, site monitoring wells exhibiting statistically anomalous analytical results will be immediately re-sampled in order to confirm the SSI. The following flexible procedures will be followed with regard to the performance of verification re-sampling and assessment monitoring at the subject landfill:

- If a confirmed SSI occurs for a constituent that is listed in 30 TAC 330.419 assessment monitoring will be initiated within ninety (90) days of the date of the SSI notice to the TCEQ Executive Director per 30 TAC §330.407 (b)(1) unless it can be adequately demonstrated that the SSI is due to a source other than the landfill, or that it resulted from error in sampling, analyses, statistical evaluation, or natural variation in ground water quality.

Assessment monitoring will be performed on a site-specific basis in accordance with *30 TAC §330.409*. Although the initiation of assessment monitoring does not require TCEQ concurrence, these activities will be coordinated with TCEQ to confirm adequate characterization of potential ground water contamination.

13 QUALITY ASSURANCE AND QUALITY CONTROL (QA/QC)

The assessment of data reliability is essential to determine if the analytical parameters detected by the contract laboratory are truly present in the ground water at the reported concentrations and to confirm that all compounds of interest in the sample have been detected. A good QA/QC program confirms that the data generated are accurate, precise, and legally defensible and enhances consistency in data analysis.

Quality assurance and quality control (QA/QC) procedures address both the field and laboratory activities. In order to provide good QA/QC for field data generated during background and detection monitoring at the subject landfill, project documentation for each monitoring event will include descriptions of the following areas and activities at a minimum. Specific discussions pertaining to items listed below are provided in the preceding sections of this GWSAP.

- The location where decontamination of sampling equipment is to be performed, the method, solvents, and purity of water used for decontamination purposes, and the method and storage location for purged ground water generated as a result of sampling activities.

- Sample management procedures including the container types, volume of samples, preservatives, labeling, holding times, chain-of-custody documentation, and shipping methods.

- Field equipment and instrumentation used in the field including calibration and maintenance procedures.

- Sample collection information including the names of field personnel, sample numbers, dates and times, climatic conditions, and documentation QC samples including trip and equipment blanks, and duplicate samples.

Laboratory QA/QC procedures will be established and followed for the analyses of samples from the subject landfill in order to reduce the frequency of random and systematic errors and to maintain such errors within tolerable limits. As referenced in ***Section 1.0: Introduction and Purpose*** of this GWSAP, the contract analytical laboratory will provide an LSOP for TCEQ review prior to the implementation of the background monitoring program in partial fulfillment of QA/QC requirements. The LSOP will describe a detailed program of how the laboratory will proceed to provide data of stated quality with stated probability of being correct including all procedures to handle and analyze samples from receipt until results are reported. At a minimum, the laboratory QA/QC program described in the LSOP will address the following:

- Procedures will be in place for demonstrating proficiency with each analytical method used in the laboratory including documentation of precision, bias, methods and frequency of the determinations of method detection limits (MDLs), check on reagent purity and glassware purity, and check on spike and surrogate recoveries.

- The laboratory will have methods in place for establishing control limits for analysis, documenting the effect of the matrix on analytical results, and reviewing, approving, and revising laboratory records.

- The laboratory will maintain equipment records documenting the frequency of equipment maintenance, standards used, calibration history, and verification of all work standards against appropriate primary grade standards.

- The laboratory will maintain records including descriptions of samples received, steps of sample handling, assigned personnel responsibilities, chain-of-custody, and reagents used and date of purchase.

- The laboratory will maintain in permanent records the raw data and calculated results for all QC, field samples, and standards.

13.1 Trip Blanks

Trip blanks are used to test whether sample bottles or collected samples may have been contaminated before or during sampling, or whether sample shipment, handling and storage may have had an effect on sample integrity. Trip blanks, supplied by the contract laboratory containing laboratory-grade water, will be prepared and sent from and to the laboratory in the same manner as actual ground water samples. One properly preserved trip blank will accompany sampling personnel into the field during each sampling event and subsequently analyzed for VOCs specified in ***Table Att11-2***.

13.2 Field Blanks

Field blanks are used to test sampling procedures and evaluate potential airborne contaminants. Field blanks will be prepared by sampling personnel in the field by placing laboratory-grade water, into clean sample containers. Pending the initial determination of ground water gradient at the site, field blanks will be collected when sampling downgradient wells. At a minimum, one field blank per day or per every ten (10) wells, whichever is greater, will be collected and analyzed for VOCs listed in ***Table Att11-2*** for each monitoring event.

13.3 Equipment Blanks

Equipment blanks are used to test the effectiveness of decontamination procedures for sampling equipment. Equipment blanks will be prepared by sampling personnel by procession laboratory-grade water trough the sampling equipment (i.e., bailer or pump) in the same manner as the

actual ground water samples obtained for site monitoring wells. One equipment blank per day will be collected and analyzed for VOCs listed in ***Table Att11-2*** during each monitoring events.

13.4 Field Duplicates

Field duplicates will be collected in order to test the precision of laboratory techniques. Duplicates will be prepared by collecting two ground water samples from the same well, preferably from the same sampling device, but labeled differently, so that the analytical laboratory is unaware that the samples are duplicate. One field duplicate will be collected per ten (10) wells sampled, or per sampling event for fewer than ten (10) wells and analyzed for parameters listed in ***Table Att11-2***.

14 STATISTICAL METHODS

Statistical analysis will be provided in accordance with 30 TAC §330.405. The purpose of the statistical evaluation of ground water data is to determine whether "there is evidence of a SSI from background values for each detection /monitoring constituent required as part of the ground water monitoring." *30 TAC §330.405* allows the use of a wide variety of statistical methods but requires that the method chosen for a constituent be appropriate for the constituent, for the data available, and for the site. It is crucial to select appropriate statistical methods for a variety of reasons: the necessity of being able to detect a release from the subject landfill in a timely way, the ability to evaluate data clearly and quickly, and the intent to detect SSIs that may indicate contamination.

Appropriate statistical methods cannot be chosen in advance of sampling as specific methods depend upon the distribution of data, although it is possible to establish guidelines for the application of statistical methods to analytical data prior to sampling. Therefore, a general discussion pertaining to the application of statistical methods to background and detection monitoring is presented in ***Section 14.1: Statistical Comparisons*** of this GWSAP. Information provided in ***Section 14.1*** is based to a large extent upon recommendations set forth in the following publications:

- American Society for Testing and Materials (ASTM), 1998; *Standard Guide for Developing Appropriate Statistical Approaches for Ground Water Detection Monitoring Programs, (Designation: D 6312-98).*

- EPA, Office of Solid Waste, Waste Management Division, 1989; *Statistical Analysis of Ground-Water Monitoring Data and RCRA Facilities, Interim Final Guidance, April 1989.*

- EPA, Office of Solid Waste, Waste Management Division, 1992; *Statistical Analysis of Ground-Water Monitoring Data at RCRA Facilities, Draft Addendum to Interim Final Guidance, July 1992.*

Subsequent to the completion of background monitoring, a plan outlining the statistical approach to be applied to background and detection monitoring data will be submitted to TCEQ for review and approval prior to implementation. The statistical plan will compliment the GWSAP, utilize, site specific analytical data, and present a more detailed approach than described herein.

14.1 Statistical Comparisons

Three types of statistical comparisons are possible at a site with more than one monitoring well for background and detection monitoring:

1) the current data for a well may be compared to the historical data for that same well (intrawell comparison);

2) one downgradient well may be compared to one or a group of upgradient wells (interwell comparison); and

3) a variation of the second type, a group of downgradient wells may be compared to a group of upgradient wells.

In the event that a SSI is detected and assessment monitoring is conducted, a fourth type of statistical comparison may be employed involving the comparison of well data to a constant limit such as a maximum concentration limit (MCL).

A serious difficulty associated with the comparison of downgradient water quality with upgradient water quality is the underlying assumption that the two sets of data are from water that has everywhere had an identical history. This assumption would imply that the upgradient and downgradient water would have the same infiltration time, period of contact with water-bearing sediments, chemical reactions with passing constituents, and no other significant differences from one part of the water-bearing zone to another. Although such assumptions are often necessary to make comparisons, they are generally not realistic with regard to natural ground water systems.

Intrawell comparisons are generally preferable to their interwell counterparts because they completely eliminate the spatial component of variability in samples. Due to the absence of spatial variability, the uncertainty associated with measured concentrations is decreased, making intrawell comparisons more sensitive to real releases (that is, false statistical negatives), and false positives. For sites where the hydraulic gradient is indefinite, the intrawell comparison is probably the most useful treatment of ground water sampling data. As per the above discussion, it is anticipated that intrawell comparisons will be applied to sampling data generated at the subject landfill following the completion of eight background monitoring events.

Flow charts can be valuable tools, aiding in the selection of appropriate statistical methods. A flow chart depicting methods likely to be used along with decision points of basis for making selections has been included in this GWSAP as ***Figure Att11-3***. It is anticipated that this format will allow for future flexibility contingent upon analytical data and minimize potential future changes to this plan. Information provided in the referenced figure was adapted from the example provided in ASTM publication *D 6312-98*.

Detailed descriptions of the selected statistical comparison method(s), decision points, and specific statistical treatments presented in the referenced flow chart will be provided to TCEQ in a statistical plan subsequent to the completion of background monitoring. Descriptions of

specific methods presented in the statistical plan will include appropriate information pertaining to normality of data, statistical intervals, and the handling on non-detects. A description of graphical methods to be applied to monitoring data will additionally be discussed in the statistical plan.

14.2 Independent Samples

Statistical methods generally used in ground water monitoring require that data be statistically independent for the results to be strictly valid. The sampling frequency must be established such that sufficient elapsed time occurs between monitoring events ensuring that consecutive samples are not taken from the "same" water. In general, the more permeable the water-bearing zone and the steeper the hydraulic gradient, the less time is necessary between monitoring events to facilitate the collection of statistically independent samples.

As discussed briefly in ***Section 10.0: Background Samples*** of this GWSAP, background monitoring events will be conducted quarterly for a duration of two years in order to construct a background database consisting of eight statistically independent samples per well. In order to confirm the adequacy of a quarterly monitoring program, site-specific lithologic and depth-to-water information including measurements/estimations of effective porosity, ground water gradient, and hydraulic conductivity will be used to calculate the horizontal ground water flow velocity. Given the diameter of site monitoring wells, it will be possible to determine whether flow velocities are such that water within the well casing will completely change within the three-month duration between monitoring events.

In the event that the site-specific determination of ground water flow velocity indicates that an alternate monitoring frequency is warranted (i.e., semi-annual as opposed to quarterly), a revised frequency will be proposed to TCEQ for remaining background and detection monitoring events as a permit modification request.

14.3 Seasonal Variation

Seasonal variation of ground water chemistry is well known in the state of Texas. Determination of seasonal influences requires adequate data, i.e., data collected over a full range of seasons, in order to make proper adjustments. Therefore, as described in ***Section 10.0: Background Sample*** of this GWSAP, a total of eight background sampling events will be conducted quarterly over a duration of two years in order to obtain data that reflects seasonal variations in ground water chemistry. By incorporating such data into the background monitoring database, it is anticipated that seasonal influences on the statistical treatment of data collected during detection monitoring events can be minimized.

15 REPORTING AND SUBMITTALS

Statistical analysis will be performed no later than 60 days after each semi-annual sampling event. In the event that statistical analysis of the groundwater analytical results indicates an initial SSI from background of any tested constituent at any downgradient monitor well, a notice in writing to the executive director and any local pollution agency with jurisdiction that has requested to be notified will be submitted within fourteen (14) days after the determination of the SSI (30 TAC §330.407 (b)). Three (3) copies (triplicate) of an annual detection monitoring report describing groundwater sampling and analyses results will be completed on state reporting forms (e.g. TCEQ-0312 or subsequent versions) and will be submitted to the TCEQ no later than ninety (90) days after the facility's last groundwater sampling event in a calendar year and will include information determined since the previously submitted annual report (30 TAC §330.407 (c)). In accordance with 30 TAC §330.407 (c)(1) to (6), the following information will be included in the annual detection monitoring report:

- A statement regarding whether a statistically significant increase has occurred over background values in any well during the previous calendar year period and the status of any statistically significant increase events;
- The results of all groundwater monitoring, testing, and analytical work obtained or prepared under the requirements of 30 TAC §330, including a summary of background groundwater quality values, groundwater monitoring analyses, statistical calculations, graphs, and drawings;
- The groundwater flow rate and direction in the uppermost aquifer. The groundwater flow rate and direction of groundwater flow shall be established using the data collected during the preceding calendar year's sampling events from the monitoring wells of the Detection Monitoring Program. All documentation used to determine the groundwater flow rate and direction of groundwater flow shall also be included in the annual report;
- A contour map of piezometric water levels in the uppermost aquifer based, at a minimum, upon concurrent measurement in all monitoring wells. All data or documentation used to establish the contour map will be included in the annual report;
- Recommendations for any changes; and
- Any other items requested by the executive director.

If an SSI occurs, assessment monitoring will be initiated according to the specified timelines presented in ***Section 12.0: Assessment Monitoring*** of this GWSAP unless it is demonstrated within the allotted time that the SSI is due to an error, natural variation, or another source. If initiated, assessment monitoring will be performed on a site-specific basis in accordance with *30 TAC §330.409.* Although the initiation of assessment monitoring does not require TCEQ

concurrence, these activities will be coordinated with TCEQ to confirm adequate characterization of potential ground water contamination.

In the event that statistical analysis of the groundwater analytical results indicates an initial SSI from background of any tested constituent at any downgradient monitor well, a notice in writing to the executive director and any local pollution agency with jurisdiction that has requested to be notified will be submitted within fourteen (14) days after the determination of the SSI (30 TAC §330.407 (b)). In the event the facility is in assessment monitoring, three (3) copies (triplicate) of an annual assessment monitoring report describing groundwater sampling and analyses results will be completed on state reporting forms (e.g. TCEQ-0312 or subsequent versions) and will be submitted to the TCEQ no later than sixty (60) days after the facility's last groundwater sampling event in a calendar year and will include information determined since the previously submitted annual report (30 TAC §330.409 (k)). Data may also be required to be submitted to the TCEQ on diskette or another format as specified by the TCEQ. In accordance with 30 TAC §330.409 (k)(1) to (6), the following information will be included in the annual assessment monitoring report:

- A statement whether a statistically significant level above a groundwater protection standard (GWPS) established in 30 TAC §330.407 (h) or (i) has occurred in any well during the previous calendar year period and the status of any statistically significant level events;
- The results of all groundwater monitoring, testing, and analytical work obtained or prepared under the requirements of 30 TAC §330, including a summary of background groundwater quality values, groundwater monitoring analyses, statistical calculations, graphs, and drawings;
- The groundwater flow rate and direction in the uppermost aquifer. The groundwater flow rate and direction of groundwater flow shall be established using the data collected during the preceding calendar year's sampling events from the monitoring wells of the Assessment Monitoring Program. All documentation used to determine the groundwater flow rate and direction of groundwater flow shall also be included in the annual report;
- A contour map of piezometric water levels in the uppermost aquifer based, at a minimum, upon concurrent measurement in all monitoring wells. All data or documentation used to establish the contour map will be included in the annual report;
- Recommendations for any changes; and
- Any other items requested by the executive director.

16 HEALTH AND SAFETY

A site-specific health and safety plan will be maintained independent of GWSAP due to the potential changes and updates of information such as emergency contacts and telephone numbers. This plan will include a summary of work tasks, site conditions, parties involved, and assigned responsibilities. The plan will describe emergency communications and response procedures with emphasis on the types of potential and existing hazards, exposure routes, Material Safety Data Sheets information, escape routes, personal protective equipment, first aid, and routes to the nearest hospital. A general site location map and detailed facility map will be included as part of the health and safety plan.

In summary, the permittee and/or subcontractors performing functions specific to activities associated with, and identified in the GWSAP, will establish and implement, and maintain appropriate health and safety plans.

LABORATORY CHECKLIST

Laboratory Data Package Cover Page

This data package consists of:

- ☐ This signature page, the laboratory review checklist, and the following reportable data:
- ☐ R1 Field chain-of-custody documentation;
- ☐ R2 Sample identification cross-reference;
- ☐ R3 Test reports (analytical data sheets) for each environmental sample that includes:
  - a) Items consistent with NELAC 5.13 or ISO/IEC 17025 Section 5.10
  - b) dilution factors,
  - c) preparation methods,
  - d) cleanup methods, and
  - e) if required for the project, tentatively identified compounds (TICs).
- ☐ R4 Surrogate recovery data including:
  - a) Calculated recovery (%R), and
  - b) The laboratory's surrogate QC limits.
- ☐ R5 Test reports/summary forms for blank samples;
- ☐ R6 Test reports/summary forms for laboratory control samples (LCSs) including:
  - a) LCS spiking amounts,
  - b) Calculated %R for each analyte, and
  - c) The laboratory's LCS QC limits.
- ☐ R7 Test reports for project matrix spike/matrix spike duplicates (MS/MSDs) including:
  - a) Samples associated with the MS/MSD clearly identified,
  - b) MS/MSD spiking amounts,
  - c) Concentration of each MS/MSD analyte measured in the parent and spiked samples,
  - d) Calculated %Rs and relative percent differences (RPDs), and
  - e) The laboratory's MS/MSD QC limits
- ☐ R8 Laboratory analytical duplicate (if applicable) recovery and precision:
  - a) the amount of analyte measured in the duplicate,
  - b) the calculated RPD, and
  - c) the laboratory's QC limits for analytical duplicates.
- ☐ R9 List of practical quantitation limits (PQLs) for each analyte for each method and matrix;
- ☐ R10 Other problems or anomalies.
- ☐ The Exception Report for every "No" or "Not Reviewed (NR)" item in laboratory review checklist.

Release Statement: I am responsible for the release of this laboratory data package. This data package has been reviewed by the laboratory and is complete and technically compliant with the requirements of the methods used, except where noted by the laboratory in the attached exception reports. By my signature below, I affirm to the best of my knowledge, all problems/anomalies, observed by the laboratory as having the potential to affect the quality of the data, have been identified by the laboratory in the Laboratory Review Checklist, and no information or data have been knowingly withheld that would affect the quality of the data.

Check, if applicable: ☐☐ This laboratory is an in-house laboratory controlled by the person responding to rule. The official signing the cover page of the rule-required report (for example, the APAR) in which these data are used is responsible for releasing this data package and is by signature affirming the above release statement is true.

Laboratory Name:	LRC Date:
Project Name:	Laboratory Job Number:
Reviewer Name:	Prep Batch Number(s):

#[1]	A[2]	Description	Yes	No	NA[3]	NR[3]	ER#[4]
R1	OI	**Chain-of-custody (C-O-C)**					
		Did samples meet the laboratory's standard conditions of sample acceptability upon receipt?					
		Were all departures from standard conditions described in an exception report?					
R2	OI	**Sample and quality control (QC) identification**					
		Are all field sample ID numbers cross-referenced to the laboratory ID numbers?					
		Are all laboratory ID numbers cross-referenced to the corresponding QC data?					
R3	OI	**Test reports**					
		Were all samples prepared and analyzed within holding times?					
		Other than those results < PQL, were all other raw values bracketed by calibration standards?					
		Were calculations checked by a peer or supervisor?					
		Were all analyte identifications checked by a peer or supervisor?					
		Were sample quantitation limits reported for all analytes not detected?					
		Were all results for soil and sediment samples reported on a dry weight basis?					
		Were % moisture (or solids) reported for all soil and sediment samples?					
		If required for the project, TICs reported?					
R4	O	**Surrogate recovery data**					
		Were surrogates added prior to extraction?					
		Were surrogate percent recoveries in all samples within the laboratory QC limits?					
R5	OI	**Test reports/summary forms for blank samples**					
		Were appropriate type(s) of blanks analyzed?					
		Were blanks analyzed at the appropriate frequency?					
		Were method blanks taken through the entire analytical process, including preparation and, if applicable, cleanup procedures?					
		Were blank concentrations < PQL?					
R6	OI	**Laboratory control samples (LCS):**					
		Were all COCs included in the LCS?					
		Was each LCS taken through the entire analytical procedure, including prep and cleanup steps?					
		Were LCSs analyzed at the required frequency?					
		Were LCS (and LCSD, if applicable) %Rs within the laboratory QC limits?					
		Does the detectability data document the laboratory's capability to detect the COCs at the MDL used to calculate the SQLs?					
		Was the LCSD RPD within QC limits?					
R7	OI	**Matrix spike (MS) and matrix spike duplicate (MSD) data**					
		Were the project/method specified analytes included in the MS and MSD?					
		Were MS/MSD analyzed at the appropriate frequency?					
		Were MS (and MSD, if applicable) %Rs within the laboratory QC limits?					
		Were MS/MSD RPDs within laboratory QC limits?					
R8	OI	**Analytical duplicate data**					
		Were appropriate analytical duplicates analyzed for each matrix?					
		Were analytical duplicates analyzed at the appropriate frequency?					
		Were RPDs or relative standard deviations within the laboratory QC limits?					
R9	OI	**Practical quantitation limits (PQLs):**					
		Are the PQLs for each method analyte included in the laboratory data package?					
		Do the PQLs correspond to the concentration of the lowest non-zero calibration standard?					
		Are unadjusted PQLs included in the laboratory data package?					
R10	OI	**Other problems/anomalies**					
		Are all known problems/anomalies/special conditions noted in this LRC and ER?					
		Were all necessary corrective actions performed for the reported data?					
		Was applicable and available technology used to lower the SQL minimize the matrix interference affects on the sample results?					

1. Items identified by the letter "R" must be included in the laboratory data package submitted in required report(s). Items identified by the letter "S" should be retained and made available upon request for the appropriate retention period.
2. = organic analyses; I = inorganic analyses (and general chemistry, when applicable);
3. NA = Not applicable; and NR = Not reviewed;
4. ER# = Exception Report identification number (an Exception Report should be completed for an item if "NR" or "No" is checked on the LRC)

S1	OI	**Initial calibration (ICAL)**					
		Were response factors and/or relative response factors for each analyte within QC limits?					
		Were percent RSDs or correlation coefficient criteria met?					
		Was the number of standards recommended in the method used for all analytes?					
		Were all points generated between the lowest and highest standard used to calculate the curve?					
		Are ICAL data available for all instruments used?					
		Has the initial calibration curve been verified using an appropriate second source standard?					
	OI	**Initial and continuing calibration verification (ICCV and CCV) and continuing calibration**					
		Was the CCV analyzed at the method-required frequency?					
		Were percent differences for each analyte within the method-required QC limits?					
		Was the ICAL curve verified for each analyte?					
		Was the absolute value of the analyte concentration in the inorganic CCB < MDL?					
	O	**Mass spectral tuning:**					
		Was the appropriate compound for the method used for tuning?					
		Were ion abundance data within the method-required QC limits?					
	O	**Internal standards (IS):**					
		Were IS area counts and retention times within the method-required QC limits?					
S5	OI	**Raw data (NELAC section 1 appendix A glossary, and section 5.12 or ISO/IEC 17025 section 4.12.2)** ***(ONLY USE DATA FOR EPA LEVEL 3 QA/QC REVIEW, IF RAW DATA NOT APPLICATBLE, THEN CHANGE APPROPRIATELY).***					
		Were the raw data (for example, chromatograms, spectral data) reviewed by an analyst?					
		Were data associated with manual integrations flagged on the raw data?					
	O	**Dual column confirmation**					
		Did dual column confirmation results meet the method-required QC?					
	O	**Tentatively identified compounds (TICs):**					
		If TICs were requested, were the mass spectra and TIC data subject to appropriate checks?					
	I	**Interference Check Sample (ICS) results:**					
		Were percent recoveries within method QC limits?					
	I	**Serial dilutions, post digestion spikes, and method of standard additions**					
		Were percent differences, recoveries, and the linearity within the QC limits specified in the method?					
	OI	**Method detection limit (MDL) studies**					
		Was a MDL study performed for each reported analyte?					
		Is the MDL either adjusted or supported by the analysis of DCSs?					
	OI	**Proficiency test reports:**					
		Was the laboratory's performance acceptable on the applicable proficiency tests or evaluation studies?					
	OI	**Standards documentation**					
		Are all standards used in the analyses NIST-traceable or obtained from other appropriate sources?					
	OI	**Compound/analyte identification procedures**					
		Are the procedures for compound/analyte identification documented?					
	OI	**Demonstration of analyst competency (DOC)**					
		Was DOC conducted consistent with NELAC Chapter 5C or ISO/IEC 4?					
		Is documentation of the analyst's competency up-to-date and on file?					
	OI	**Verification/validation documentation for methods** (NELAC Chap 5 or ISO/IEC 17025 Section 5)					
		Are all the methods used to generate the data documented, verified, and validated, where applicable?					
	OI	**Laboratory standard operating procedures (SOPs):**					
		Are laboratory SOPs current and on file for each method performed?					

1 Items identified by the letter "R" should be included in the laboratory data package submitted to the TCEQ in the required report(s). Items identified by the letter "S" should be retained and made available upon request for the appropriate retention period.
2 O = organic analyses; I = inorganic analyses (and general chemistry, when applicable).
3 NA = Not applicable.
4 NR = Not Reviewed.
5 ER# = Exception Report identification number (an Exception Report should be completed for an item if "NR" or "No" is checked).

1 INTRODUCTION AND PURPOSE

The Ground Water Sampling and Analysis Plan (GWSAP) presented herein was prepared to describe procedures and methodologies associated with the collection, handling and laboratory testing of ground water samples for the City of El Paso McCombs Landfill (MSW Permit No. 729XB The purpose of the GWSAP is to define site-specific standards and practices for ground water sampling and analysis within the context of a stand-alone document that provides a concise set of instructions to sampling and analytical personnel conducting a ground water sampling program. This GWSAP has been updated to comply with 30 TAC 330 Subchapter J: Groundwater Monitoring and Corrective Action (effective March 27, 2006). Once approved by the Texas Commission on Environmental Quality (TCEQ), this GWSAP will replace the previous GWSAP within the Site Development Plan for the City of El Paso McCombs Landfill.

The ground water sampling program will be conducted in accordance with the procedures established herein. Although the GWSAP addresses the collection, handling, storage, and treatment of the samples (both in the field and at the testing laboratory), the contract laboratory that actually performs the analyses of ground water samples will submit a Laboratory Standard Operating Procedures (LSOP) document to the TCEQ prior to the implementation of the sampling program. The LSOP will describe specific laboratory protocols used to provide data of stated quality with a stated probability of being correct including all procedures to handle and analyze samples from receipt until results are officially reported.

2 MONITORING POINT INSPECTION

The location of each monitoring point (hereinafter also referred to as "monitoring well" or "well") will be initially verified using a current site map to confirm that appropriate monitoring wells are identified for sampling. The unique well identification numbers will be verified with the identification markers shown on well installations and recorded on the field data sheet (or an equivalent form) (depicted as ***Figure Att11-1***). Field data sheets for each monitoring well will accompany field personnel performing ground water monitoring to the subject landfill during monitoring events.

Prior to the commencement of monitoring well gauging or purging activities, the condition of site wells will be visually inspected. The well casing and concrete pads will be checked for the presence of cracks or fissures that could compromise the integrity of the surface completion. Each well will be additionally inspected for damage due to vandalism, animals or insects, and/or heavy equipment operations. Descriptions of apparent well damage or conditions conducive to the transmission of surface runoff along monitoring well installations will be noted in the *"Remarks"* section of the field data sheet. If any problems are discovered, they will be repaired/replaced as soon as practicable.

3 GAS MONITORING/WATER LEVEL MEASUREMENTS

The presence of explosive gases within the well casing at respective monitoring well locations will be evaluated utilizing a properly calibrated landfill gas monitor. Measurements will consist of gas temperature, pressure, and concentration. Well casings will be screened during each monitoring event to verify that the concentration of methane gas does not exceed 25 percent of the lower explosive limit (LEL) for methane. In the event that methane is detected at concentrations that exceed 25 percent of the LEL, steps will be immediately taken to ensure the protection of human health and safety pursuant to the contingencies described in *30 TAC §330.371*. A record of field methane measurements will be recorded on the field data sheet-(or an equivalent form).

Prior to purging site monitoring wells, the depth to water and total well depth measurements will be gauged at each well location from a permanent, clearly marked reference point on the well (i.e., top of casing [TOC]). The water level measurements will be recorded to the nearest hundredth of a foot utilizing an electronic water-level indicator (e-line). To ascertain that potential contaminants are not introduced to the monitoring wells as the result of gauging activities, the e-line probe and measurement tape will be decontaminated before and after each use. Decontamination procedures are further described in **Section 4.0: Well Purging** of this GWSAP. The decontamination fluids will be containerized pending the results of ground water sampling and analyses.

4 WELL PURGING

In order to obtain representative ground water samples, the monitoring wells will be purged to remove water from the well casing that may not be chemically representative of the formation ground water. Well purging will be accomplished utilizing either a properly decontaminated submersible pump or a dedicated Teflon® or polyethylene bailer. In the event that a pump is used to purge monitoring wells, purging equipment including pump, tubing, and connectors will be decontaminated according to the following procedure:

1) Conduct an initial wash using a mild solution containing a biodegradable, phosphate-free detergent such as Alconox®;

2) Conduct a second wash utilizing clean drinking-grade water; and

3) Conduct a final rinse using reagent-grade water obtained from the analytical laboratory.

In order to prevent cross-contamination of purging equipment by field personnel, clean, disposable, powder-free, nitrile or latex gloves will be used when handling the decontaminated purging equipment. Prior to purging and sampling, clean, disposable plastic sheeting will be placed around respective wells in order to prevent clean equipment from coming into contact with the ground.

During purging, a minimum of three (3) well casing volumes of ground water will be removed from respective monitoring wells. As indicated on the attached field data sheet (please see ***Figure Att11-1***), the volume of water to be removed at each well location will be calculated based on the respective height of the water column in the monitoring well and the well casing diameter. If sufficient ground water is available, purging will continue until field parameters including pH, temperature, turbidity, and conductivity have stabilized and the ground water is clear. A description of measurement protocols for field parameters is provided in **Section 6.2: Field Measurements** of this GWSAP. Parameter stabilization is defined as:

- Specific Conductivity = ± 10% for three (3) consecutive measurements;
- pH = ± 0.2 standard pH units for three (3) consecutive measurements;
- Temperature = ± 10% for three (3) consecutive measurements;
- Turbidity = ± 10% for three (3) consecutive measurements unless under 10 NTU (all values under 10 NTU are considered stable).

In the event that monitoring wells recharge very slowly, wells will be purged to dryness in order to remove stagnant water from well casings. Wells will be allowed sufficient time (maximum of 72 hours) to recover such that ground water samples can be collected. Whenever possible, the ground water level shall be allowed to recover to within 90 percent of the original water level measurement prior to sampling. In the event that sufficient well volume for sampling is not available within 72 hours of purging, it is understood that TCEQ may require a longer duration for recovery of sufficient sampling volume or the adoption of an alternate strategy to obtain samples from low-yield wells. As further described in **Section 6.1** of this GWSAP, site conditions may facilitate the application of Low-Flow Purging and Sampling Techniques as an alternative to conventional well purging and sampling methods described above.

All data collected prior to sampling will be recorded on the field data sheet (or an equivalent form) and will include the following, at a minimum:

- initial depth to water,
- measured depth to the bottom of the well,
- height of the water column inside the well,
- well casing volume,
- purging rate,
- time spent purging the well,
- water volume purged from the well,
- a record of pH, conductivity, temperature, turbidity readings, and
- information resulting form the well inspection and other pertinent information.

Ground water removed from site monitoring wells during purging activities will be stored in labeled 55-gallon drums or similar containers. The ground water containers will be temporarily stored on site until analytical results are received from the contract laboratory. If the report of laboratory analyses indicates that the concentrations of contaminants do not exceed levels of concern as determined by TCEQ, the water will be applied to the unsaturated soil on-site. In the event that analytical results indicate concentrations of contaminants that are above levels of concern or classified as hazardous by TCEQ, the water will be properly disposed of at a wastewater treatment facility, hazardous waste facility, or other authorized facility in accordance with applicable TCEQ and federal regulations.

5 TIMING AND ORDER OF SAMPLING

In association with each monitoring event, ground water sampling will be accomplished as soon as practicable subsequent to the completion of purging activities to avoid temporal variations in water levels and water chemistry. When possible, sampling activities will be conducted within twenty-four (24) hours of well purging. As described in **Section 4.0: Well Purging** of this GWSAP, a maximum of 72 hours will be allowed subsequent to purging in the event that monitoring wells recharge slowly and sufficient water volume is not available for sampling at a lesser duration. In the event that sufficient well volume for sampling is not available within 72 hours of purging, it is understood that TCEQ may require a longer duration for recovery of sufficient sampling volume or the adoption of an alternate strategy to obtain samples from low-yield wells. In general, the time interval between purging and sampling activities will be kept to a minimum, particularly when the analysis of volatile organic compounds (VOCs) is required.

In an effort to avoid cross-contamination of samples between monitoring wells during respective monitoring events, sampling will commence at the monitoring well which is known to be the least contaminated and conclude with the most contaminated well. In the absence of contamination data for newly installed monitoring wells during initial background monitoring events, the order of sampling will be from the well with the highest water-level elevation to the well with the lowest elevation (upgradient to downgradient) for each group of wells completed within a discrete water bearing interval.

6 SAMPLE COLLECTION, PRESERVATION, AND SHIPMENT

In an effort to maximize the validity of ground water samples and protect sample integrity, the following procedures for sample collection, preservation, and shipment will be implemented. The methods and procedures described herein will be consistently applied at site monitoring wells and throughout subsequent ground water monitoring events.

6.1 Sample Collection

Ground water samples will be collected at each well location utilizing a pump or a new, clean, disposable bailer suspended from new, clean nylon string. In order to minimize turbulence and aeration and associated potential volatilization of organic compounds during sampling, adjustable flow rate pumps will be used or bailers will be equipped with a bottom-emptying device allowing water to be discharged slowly from the bottom directly into sample containers. Field personnel will wear new, clean, disposable nitrile or latex gloves throughout the duration of sampling at each well location. Soiled sample bottles, bailers, nylon string, and filtration media will not be reused at subsequent well sampling locations.

In the event that ground water samples are collected immediately subsequent to purging activities (6 to 12 hours), it is not anticipated that ground water present at the top of the water column will be oxidized to an extent that could potentially affect the collection of representative ground water samples. In the event that sufficient sample volume recharges into monitoring wells and sampling is conducted within 24 hours of purging the first portion of collected water (approximately 2 liters [i.e., 0.5 gallons]) will be discarded to eliminate potentially oxidized water prior to filling sample containers. In the event that site wells recharge slowly and must be sampled more than 24 hours after purging, a lesser volume may be initially discarded in order to preserve sufficient sampling volume for analytical chemistry assignments.

In the event that site wells recharge slowly, low-flow purging and sampling techniques in accordance with guidance contained in EPA publication *EPA/540/S-95/504, Low-Flow (Minimal Drawdown) Ground Water Sampling Procedures (April 1996)*, may be adopted as an alternative to conventional purging and sampling methods described in **Section 4.0** of this GWSAP. If low-flow procedures are to be used, a demonstration of the suitability of low-flow procedures will be prepared and submitted to TCEQ for review and acceptance prior to implementation.

6.2 Field Measurements

An unfiltered portion of the ground water will be poured into a clean container for field measurement of temperature, specific conductance, and pH. The temperature readings will be measured immediately upon collection. Subsequently, measurements of specific conductance

will be accomplished to avoid any effect on the sample from salts on the pH probe. The specific conductance readings will be followed by the pH measurements. In addition to recording ground water parameter measurements, observations regarding the ground water color, odor, foaming, presence of more than one phase of liquid, and turbidity will be recorded on the field data sheet (or an equivalent form).

Equipment utilized for the field measurements will be calibrated each day that the equipment is used in the field. Copies of the daily calibration logs will be kept on file. Provisions will be made for backup equipment in the event of a primary equipment failure during the course of a monitoring event.

6.3 Sample Containers

The volume of samples and the types of sample containers depends on the parameters to be analyzed during respective monitoring events and will be consistent with EPA guidance. Sampling, preservation, and storage procedures for potential ground water monitoring parameters are presented in ***Table Att11-1***.

Sample containers will be filled in the following order according to volatilization sensitivity:

1. **VOCs** (volatile organic compounds)
2. **SVOCs** (semi-volatile organic compounds) (if collected)
3. **Metals**
4. **Other Inorganic Parameters** (if collected)

Although volatilization is of primary concern during VOC sampling, designated VOC vials will additionally be sampled from the same bailer or directly from the pump in order to prevent inhomogeneity in the samples resulting from the presence of suspended sediments. Inhomogeneity of samples owing to the presence of suspended sediments is additionally of concern when collecting samples with a bailer to the extent that VOCs adsorbed to sediment particles can influence measured concentrations in ground water. However, as wells were or will be properly designed, constructed, and installed, it is not anticipated that appreciable suspended sediments will be encountered during sampling activities.

The contract analytical laboratory will supply appropriate pre-preserved sampling containers, labeled by analyte, prior to the mobilization of sampling personnel to the subject landfill. Sample containers will be subsequently labeled in the field for identification purposes and will include the following information at a minimum: site identification, monitoring well number, date and time of sample collection, type of preservatives used, analyses to be performed (in accordance with laboratory designation), and the name of the sampler. Information will be written on laboratory-supplied sample labels using indelible ink and covered with transparent tape to protect written data.

6.4 Types of Sample Containers

As referenced in ***Table Att11-1*** of this GWSAP, the following sample containers and protocols will be utilized during ground water monitoring at the subject landfill.

- VOCs: Two (2) 40-ml glass vials with special caps containing Teflon septa will be used per analysis. Containers will be pre-preserved with HCL by the contract laboratory. Prior to filling, the septum of each vial will be placed with the Teflon side toward the sample. During filling, water will be allowed to stream down the inner wall of the vial to minimize formation of air bubbles. The vials will be slightly overfilled in order to create a positive meniscus. Upon completion of filling, caps will be carefully screwed on to avoid leaving any airspace within the vials. In the event that an air bubble forms in a vial subsequent to capping, an additional separate 40-ml sample will be collected.

- SVOCs (if collected): One (1) amber one-liter glass bottle with Teflon-lined cap will be used per analysis. Containers will be completely filled and capped.

- Metals: One (1) one-liter polyethylene bottle, pre-preserved with HNO_3 by the contract laboratory, will be used per analyses for total metals. Containers will be completely filled and capped. Groundwater samples for constituents in Appendices I and II to Title 40 Code of Federal Regulations, Part 258 will not be filtered in the field or the laboratory prior to analysis.

- Other Inorganic Parameters (if collected): Depending on the specific parameters to be analyzed, one or more glass/plastic one-liter containers will be used per analyses of the suite of inorganic parameters including those listed on ***Table Att11-1***. With the exception of ammonia (in the event that it is assigned for analysis), preservatives will not be used on samples collected for other inorganic parameter analyses.

6.5 Sample Preservation and Holding Times

Sample preservation is intended to 1) retard biological action, 2) retard hydrolysis, and 3) reduce sorption effects. Preservation methods are generally limited to pH control, chemical addition, refrigeration, and protection from light. Specific preservation methods for analytes that may be assigned in association with ground water monitoring at the subject landfill are presented in ***Table Att11-1***.

Specific sample volumes required for each analysis and associated sample holding times will be reviewed with the contract analytical laboratory prior to sampling. In general, these requirements will be consistent with those presented in ***Table Att11-1***.

6.6 Sample Storage and Transport

In accordance with preservation requirements presented in ***Table Att11-1***, sample containers will be placed into a clean, insulated cooler and kept on ice following sample collection. Adequate

ice will be kept on the samples to maintain a maximum temperature of 4°C (39.2°F) during transport to the contract analytical laboratory. The samples will be kept in the sampler's possession at all times, unless samples are shipped to the laboratory by a courier, and will be submitted to the laboratory via proper chain-of-custody protocol within forty-eight (48) hours of sampling.

6.7 Chain-of-Custody Documentation

Appropriate Chain-of-Custody (COC) procedures will be implemented to protect sample integrity and to provide technically and legally defensible ground water quality data. At any time that a ground water monitoring event is conducted, a COC form will be completed, placed in a sealable plastic bag, and placed in the cooler with the samples collected. The completed COC form will accompany the samples at every step from the field to the laboratory and will be signed by each party handling the samples, from sampler, through transporter to the laboratory to document the possession of the samples at all times. An example COC form is provided as ***Figure Att11-2*** of this GWSAP.

In the event that samples are sent by mail to the contract analytical laboratory, packages containing samples will be certified with return receipt requested to document shipment. If the samples are shipped via overnight courier, the bill of lading will be retained to document shipment. Copies of the return receipt/bill of lading will be subsequently attached to the COC at the completion of each stage of shipment.

6.8 Documentation of Sampling

As described in ***Sections 2.0 though 4.0*** of this GWSAP, information related to a sampling event will be recorded on the field data sheet (or an equivalent form) (***Figure Att11-1***). All entries will be legible and made in indelible black ink. Entry errors will be crossed out with a single line, dated, and initialed by the person making the corrections. Sufficient information including sample location, date, time, weather, and affiliation of field personnel, field measurements including the numerical values and units, the integrity of the well, methane gas measurements, etc. will be recorded on field data sheets such that the monitoring event can be reconstructed without relying on the sampler's memory. Completed field data sheets will be maintained in project files as a permanent record of ground water monitoring activities and submitted to TCEQ along with the standard ground water sampling report forms (TCEQ-0312) for respective sampling events.

Pursuant to directives issued by the MSW Permits Section effective February 1, 2001, ground water sampling reports will be submitted in electronic format, in addition to paper copies. Electronic versions of the ground water sampling reports will be submitted in accordance with procedures established by TCEQ in place at the time of sampling.

7 ANALYTICAL PARAMETERS

The detection monitoring constituents at the facility will be as specified in 30 TAC §330.419 and 40 Code of Federal Regulations (CFR) 258 Appendix I (see ***Table Att11-2*** of this GWSAP). The practical quantitation limit (PQL) for each constituent will be the lowest concentration level that can be reliably achieved within specified limits of precision and accuracy during routine laboratory operating conditions that are available to the facility, per 30 TAC §330. 405(f)(5).

The practical quantitation limit (PQL) is defined as the lowest concentration reliably achieved within specified limits of precision and accuracy during routine laboratory operating conditions and is analogous to the limit of quantitation (LOQ) definition in the most recent available NELAC Standard (National Environmental Laboratory Accreditation Conference). The PQL is method, instrument, and analyte specific and may be updated as more data becomes available. The PQL must be below the groundwater protection standard established for that analyte as defined by 30 Texas Administrative Code Section §330.409(h) unless approved otherwise by the TCEQ. The precision and accuracy of the PQL shall be initially determined from the PQLs reported over the course of a minimum of eight groundwater monitoring events.

The results obtained from these events shall be used to demonstrate that the PQLs meet the specified precision and accuracy as shown in the table below. The PQL will be supported by analysis of a PQL check sample, which is a laboratory reagent grade sample matrix spiked with chemicals of concern at concentrations equal to or less than the PQL. At a minimum, a PQL check sample will be performed quarterly during the calendar year to demonstrate that the PQL continues to meet the specified limits for precision and accuracy as defined in the table below.

QC Specification Limits for the PQL and Lower Limit of Quantitation Check Samples

COC	Precision (% RSD)	Accuracy (% Recovery)
Metals	10	70-130
Volatiles	20	50-150
Semi-Volatiles	30	50-150

For analytes that the established PQL cannot meet the precision and accuracy requirements in the table above, the owner/operator will ensure the laboratory will submit sufficient documentation and information to the TCEQ for alternate precision and accuracy limits on a case by case basis. Non-detected results will be reported as less than the established PQL limit that meets these precision and accuracy requirements.

It is not considered likely that metals including antimony, beryllium, thallium, and vanadium will be present in ground water present beneath a municipal solid waste landfill (MSWLF). After the completion of the background monitoring program, it is anticipated that the omission of some heavy metals will be proposed to TCEQ. Changes and/or modifications to the list of analytes provided in ***Table Att11-2***, if necessary, will be submitted to TCEQ in the form of a permit modification request.

8 ANALYTICAL METHODS

The ground water monitoring program described herein will include the application of appropriate analytical methods in order to accurately measure concentrations of hazardous constituents or other monitoring parameters that may be present in the ground water samples. EPA-approved methods will be utilized for analyses of ground water samples obtained at the subject landfill in accordance with procedures described in the following published references:

- EPA 600/4-79-020, *Methods for Chemical Analysis of Water and Wastes*, March 1983
- EPA SW-846, *Test Methods for Evaluating Solid Waste*, Third Edition, November 1986, and its updates.
- *Standard Methods for the Examination of Water and Wastewater*, 18th Edition, 1992.

As stipulated previously in ***Section 1.0: Introduction and Purpose*** of this GWSAP, the contract laboratory that performs analyses of ground water samples will submit a LSOP document to TCEQ prior to the implementation of the sampling program described herein. The LSOP will describe specific laboratory protocols used to provide data of stated quality with a stated probability of being correct including all procedures to handle and analyze samples from receipt until results are officially reported.

9 LABORATORY PROCEDURES AND PERFORMANCE STANDARDS

The facility will submit laboratory data and analyses prepared by a TCEQ-accredited environmental testing laboratory and in accordance with acceptable accreditation standards (e.g. NELAC).

The owner or operator shall review all analytical data submitted under the requirements of this permit to ensure compliance with data quality objectives, prior to submittal of the data to the TCEQ for review. This data review will include examination of the quality control results and other supporting data, including any data review by the laboratory. This data review will also identify any potential impacts such as bias on the quality of the data using qualifiers in the test reports tied to explanations in footnotes and in any laboratory case narrative which is required.

It is the responsibility of the owner or operator to ensure that the laboratory documents and reports all problems and anomalies observed that are associated with the analysis. If the analysis of the data indicates that it failed to meet the quality control goals for the laboratory's analytical data analysis program, it does not necessarily mean that the data is unusable. The owner or operator may still report to the TCEQ the analytical data but will also report any and all problems and corrective action that the laboratory identified during the analysis.

A Laboratory Case Narrative (LCN) report for all problems and anomalies observed will be submitted by the owner and/or operator. The LCN will report the following information:

1. State the exact number of samples, testing parameters, and sample matrix.
2. The name of the laboratory involved in the analysis. If more than one laboratory is used, all laboratories shall be identified in the case narrative.
3. State the test objective regarding samples.
4. Explain each failed precision and accuracy measurement determined to be outside of the laboratory and/or method control limits.
5. Explain if the effect of the failed precision and accuracy measurements on the results induces a positive or negative bias.
6. Identify and explain problems associated with the sample results, along with the limitations these problems have on data usability.
7. A statement on the estimated uncertainty of analytical results of the samples when appropriate and/or when requested.
8. A statement of compliance and/or noncompliance with the requirements and specifications. Exceedence of holding times and identification of matrix interferences will be identified. Dilutions shall be identified and if dilutions are necessary, they will be done to the smallest

dilution possible to effectively minimize matrix interferences and bring the sample into control for analysis.

9. Identify any and all applicable quality assurance and quality control samples that will require special attention by the reviewer.
10. A statement on the quality control of the analytical method of the permit and the analytical recoveries information shall be provided when appropriate and/or when requested.

In addition to the LCN, the following information will be submitted for all analytical data:

1. A Table identifying the field sample name with the sample identification in the laboratory report.
2. Chain of custody will be provided.
3. Analytical Report that documents the results and methods for each sample and analyte to be included for every analytical testing event. These test reports will document the reporting limit/method detection limit the laboratory used. The reporting limit for each analyte will be less than the maximum contaminant level (MCL) or as low as practically feasible per 30 TAC 330.263(b) for each of the analytes. In accordance with Appendix B of 40 CFR Part 136, the method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero and is determined from analysis of a sample in a given matrix containing the analyte.
4. A release statement will be submitted from the laboratory. This statement will state "I am responsible for the release of this laboratory data package. This data package has been reviewed by the laboratory and is complete and technically compliant with the requirements of the methods used, except where noted by the laboratory in the attached exception reports. By my signature below, I affirm to the best of my knowledge, all problems/anomalies, observed by the laboratory as having the potential to affect the quality of the data, have been identified by the laboratory in the Laboratory Review Checklist, and no information or data have been knowingly withheld that would affect the quality of the data."
    a. If it is an in-house laboratory, it will have the following statement: This laboratory is an in-house laboratory controlled by the person responding to rule. The official signing the cover page of the rule-required report (for example, the APAR) in which these data are used is responsible for releasing this data package and is by signature affirming the above release statement is true.
5. If the data is from soil and/or sediment samples, it will be reported on a dry weight basis with the percent solids and the percent moisture reported so that any back calculations of the wet analysis may be preformed.
6. Include a Laboratory checklist in the Laboratory Data Package. An example of the Laboratory checklist is provided in Appendix 1. The permittee may amend the checklist as long as it includes the information found in Appendix 1. For every response of "No, NA, or NR" that is reported on the checklist, the permittee will ensure the laboratory provides a detailed description of the "exception report" in the summary of the LCN. The phrase "exception report" in the checklist is meant to clue the owner/operator to include the

exceptions and any potential bias in the data will be in the LCN. The permittee will ask the laboratory to use the checklist and do an equivalent of an EPA Level 3 review regarding quality control analysis.

Please note the Laboratory Checklist provided in Appendix 1 is amended from the Texas Risk Reduction Prevention (TRRP) Appendix A checklist. TRRP standards and requirements for quality apply in a limited capacity only. TRRP requires an EPA Level 4 review of the data for analysis. The analytical results, quality control information, and a laboratory case narrative are essentially required by an EPA Level 3 review. Hence, the TRRP standards for an EPA Level 3 review apply; whereas, the standards of an EPA Level 4 review do not apply. The laboratory checklist is intended to aid the permittee in ensuring the laboratory did a quality control analysis and to alert one of any potential problems, bias, or anomalies during the analysis of the sample. The analytical report, LCN, and the checklist are to be included along with the TCEQ-0312 forms for all monitoring events for groundwater.

10 BACKGROUND SAMPLES

"Background" refers to the chemical characteristics of ground water comprising a data set to which the chemical characteristics of the current samples are compared to determine if the current samples show statistically significant increase (SSIs) in those characteristics. Background water quality will be established for the metals and VOCs listed in ***Table Att11-2*** of this GWSAP pursuant to 30 TAC 330.419 and 40 Code of Federal Regulations (CFR) 258 Appendix I. Additionally, water quality parameters may be sampled and analyzed at the discretion of the facility operator, but that the results will not be subject to statistical evaluation.

The spacing of background monitoring events will be adequate to facilitate the hydraulic and chemical stabilization of ground water such that consecutive samples are statistically independent. It is initially proposed that background monitoring events be conducted quarterly over the duration of two years in order to incorporate seasonal variations in water chemistry into the background data set. In the event results of initial background monitoring indicate that a quarterly frequency will not likely produce statistically independent samples based upon the calculated ground water gradient, an alternate background monitoring frequency will be proposed to TCEQ as a permit modification. The specific methodology for determining ground water sampling frequency is further discussed in ***Section 14.2: Independent Samples*** of this GWSAP.

Background samples will be collected from the site monitoring wells included as part of the ground water monitoring system. After background analyses have been completed, data will be treated statistically and background concentrations established for each parameter.

Per 30 TAC §330.407 (a)(1), semi-annual data may be incorporated into the background data set at a maximum frequency of once every two years. New data will be evaluated for any significant trends and potential outliers (or by an approved alternative method that provides equivalent or better performance). Appropriate data will then be incorporated into background with prior TCEQ approval.

A general discussion and flow chart describing the application of statistical methods to background and detection monitoring are presented in ***Section 14.0: Statistical Methods*** and ***Figure Att11-3***, respectively. In accordance with 30 TAC §330.407(a)(1), upon completion of background monitoring and during background updates, the owner or operator will evaluate the background data to ensure that the data are representative of background groundwater constituent concentrations unaffected by waste management activities or other sources of contamination, and that the evaluation will be documented in a report and submitted to the executive director before the next subsequent groundwater monitoring event following the updated (or initial) background period.

11 DETECTION MONITORING

Subsequent to the completion of background monitoring, detection monitoring will be conducted on a semi-annual basis (i.e., once every six months). The first detection monitoring event will occur approximately six (6) months after completion of background sampling pending the reduction of background sampling data. In the event that statistical analysis of the groundwater analytical results indicates an initial statistically significant increase (SSI) from background of any tested constituent at any on-site well, a notice in writing to the Executive Director and any local pollution agency with jurisdiction that has requested to be notified will be submitted within fourteen (14) days of the determination of the SSI (30 TAC §330.407(b)). In the event that a SSI occurs in ground water chemistry data, or if deemed necessary by TCEQ, and alternate monitoring frequency may be adopted. It is understood that the adoption of an alternate monitoring frequency will require TCEQ concurrence. If warranted, an alternate detection monitoring frequency will be proposed as a permit modification request.

Site wells comprising the ground water monitoring network will be sampled during each detection monitoring event in accordance with the methodologies and procedures described herein. As previously stipulated, it is anticipated that the omission of some heavy metals will be proposed to TCEQ following the completion of the background monitoring program. If warranted, proposed changes and/or modifications to the list of analytes provided in ***Table Att11-2*** will be submitted to TCEQ as a permit modification request.

12 ASSESSMENT MONITORING

The occurrence of a confirmed SSI from background for a specific detection monitoring constituent (see ***Table Att11-2***) during a sampling event will result in the implementation of assessment monitoring unless it can be adequately demonstrated that the SSI is due to a source other than the landfill, or that it resulted from error in sampling, analyses, statistical evaluation, or natural variation in ground water quality. For purposes of this GWSAP, an apparent SSI is defined as an initial statistical exceedence that has not been verified. It is understood that verification re-sampling events are essential to a satisfactory demonstration to avoid assessment monitoring. In the event that an apparent SSI is determined as the result of a detection monitoring event, site monitoring wells exhibiting statistically anomalous analytical results will be immediately re-sampled in order to confirm the SSI. The following flexible procedures will be followed with regard to the performance of verification re-sampling and assessment monitoring at the subject landfill:

- If a confirmed SSI occurs for a constituent that is listed in 30 TAC 330.419 assessment monitoring will be initiated within ninety (90) days of the date of the SSI notice to the TCEQ Executive Director per 30 TAC §330.407 (b)(1) unless it can be adequately demonstrated that the SSI is due to a source other than the landfill, or that it resulted from error in sampling, analyses, statistical evaluation, or natural variation in ground water quality.

Assessment monitoring will be performed on a site-specific basis in accordance with *30 TAC §330.409*. Although the initiation of assessment monitoring does not require TCEQ concurrence, these activities will be coordinated with TCEQ to confirm adequate characterization of potential ground water contamination.

13 QUALITY ASSURANCE AND QUALITY CONTROL (QA/QC)

The assessment of data reliability is essential to determine if the analytical parameters detected by the contract laboratory are truly present in the ground water at the reported concentrations and to confirm that all compounds of interest in the sample have been detected. A good QA/QC program confirms that the data generated are accurate, precise, and legally defensible and enhances consistency in data analysis.

Quality assurance and quality control (QA/QC) procedures address both the field and laboratory activities. In order to provide good QA/QC for field data generated during background and detection monitoring at the subject landfill, project documentation for each monitoring event will include descriptions of the following areas and activities at a minimum. Specific discussions pertaining to items listed below are provided in the preceding sections of this GWSAP.

- The location where decontamination of sampling equipment is to be performed, the method, solvents, and purity of water used for decontamination purposes, and the method and storage location for purged ground water generated as a result of sampling activities.

- Sample management procedures including the container types, volume of samples, preservatives, labeling, holding times, chain-of-custody documentation, and shipping methods.

- Field equipment and instrumentation used in the field including calibration and maintenance procedures.

- Sample collection information including the names of field personnel, sample numbers, dates and times, climatic conditions, and documentation QC samples including trip and equipment blanks, and duplicate samples.

Laboratory QA/QC procedures will be established and followed for the analyses of samples from the subject landfill in order to reduce the frequency of random and systematic errors and to maintain such errors within tolerable limits. As referenced in ***Section 1.0: Introduction and Purpose*** of this GWSAP, the contract analytical laboratory will provide an LSOP for TCEQ review prior to the implementation of the background monitoring program in partial fulfillment of QA/QC requirements. The LSOP will describe a detailed program of how the laboratory will proceed to provide data of stated quality with stated probability of being correct including all procedures to handle and analyze samples from receipt until results are reported. At a minimum, the laboratory QA/QC program described in the LSOP will address the following:

- Procedures will be in place for demonstrating proficiency with each analytical method used in the laboratory including documentation of precision, bias, methods and frequency of the determinations of method detection limits (MDLs), check on reagent purity and glassware purity, and check on spike and surrogate recoveries.

- The laboratory will have methods in place for establishing control limits for analysis, documenting the effect of the matrix on analytical results, and reviewing, approving, and revising laboratory records.

- The laboratory will maintain equipment records documenting the frequency of equipment maintenance, standards used, calibration history, and verification of all work standards against appropriate primary grade standards.

- The laboratory will maintain records including descriptions of samples received, steps of sample handling, assigned personnel responsibilities, chain-of-custody, and reagents used and date of purchase.

- The laboratory will maintain in permanent records the raw data and calculated results for all QC, field samples, and standards.

13.1 Trip Blanks

Trip blanks are used to test whether sample bottles or collected samples may have been contaminated before or during sampling, or whether sample shipment, handling and storage may have had an effect on sample integrity. Trip blanks, supplied by the contract laboratory containing laboratory-grade water, will be prepared and sent from and to the laboratory in the same manner as actual ground water samples. One properly preserved trip blank will accompany sampling personnel into the field during each sampling event and subsequently analyzed for VOCs specified in ***Table Att11-2***.

13.2 Field Blanks

Field blanks are used to test sampling procedures and evaluate potential airborne contaminants. Field blanks will be prepared by sampling personnel in the field by placing laboratory-grade water, into clean sample containers. Pending the initial determination of ground water gradient at the site, field blanks will be collected when sampling downgradient wells. At a minimum, one field blank per day or per every ten (10) wells, whichever is greater, will be collected and analyzed for VOCs listed in ***Table Att11-2*** for each monitoring event.

13.3 Equipment Blanks

Equipment blanks are used to test the effectiveness of decontamination procedures for sampling equipment. Equipment blanks will be prepared by sampling personnel by procession laboratory-grade water trough the sampling equipment (i.e., bailer or pump) in the same manner as the

actual ground water samples obtained for site monitoring wells. One equipment blank per day will be collected and analyzed for VOCs listed in ***Table Att11-2*** during each monitoring events.

13.4 Field Duplicates

Field duplicates will be collected in order to test the precision of laboratory techniques. Duplicates will be prepared by collecting two ground water samples from the same well, preferably from the same sampling device, but labeled differently, so that the analytical laboratory is unaware that the samples are duplicate. One field duplicate will be collected per ten (10) wells sampled, or per sampling event for fewer than ten (10) wells and analyzed for parameters listed in ***Table Att11-2***.

14 STATISTICAL METHODS

Statistical analysis will be provided in accordance with 30 TAC §330.405. The purpose of the statistical evaluation of ground water data is to determine whether "there is evidence of a SSI from background values for each detection /monitoring constituent required as part of the ground water monitoring." *30 TAC §330.405* allows the use of a wide variety of statistical methods but requires that the method chosen for a constituent be appropriate for the constituent, for the data available, and for the site. It is crucial to select appropriate statistical methods for a variety of reasons: the necessity of being able to detect a release from the subject landfill in a timely way, the ability to evaluate data clearly and quickly, and the intent to detect SSIs that may indicate contamination.

Appropriate statistical methods cannot be chosen in advance of sampling as specific methods depend upon the distribution of data, although it is possible to establish guidelines for the application of statistical methods to analytical data prior to sampling. Therefore, a general discussion pertaining to the application of statistical methods to background and detection monitoring is presented in ***Section 14.1: Statistical Comparisons*** of this GWSAP. Information provided in ***Section 14.1*** is based to a large extent upon recommendations set forth in the following publications:

- American Society for Testing and Materials (ASTM), 1998; *Standard Guide for Developing Appropriate Statistical Approaches for Ground Water Detection Monitoring Programs, (Designation: D 6312-98).*

- EPA, Office of Solid Waste, Waste Management Division, 1989; *Statistical Analysis of Ground-Water Monitoring Data and RCRA Facilities, Interim Final Guidance, April 1989.*

- EPA, Office of Solid Waste, Waste Management Division, 1992; *Statistical Analysis of Ground-Water Monitoring Data at RCRA Facilities, Draft Addendum to Interim Final Guidance, July 1992.*

Subsequent to the completion of background monitoring, a plan outlining the statistical approach to be applied to background and detection monitoring data will be submitted to TCEQ for review and approval prior to implementation. The statistical plan will compliment the GWSAP, utilize, site specific analytical data, and present a more detailed approach than described herein.

14.1 Statistical Comparisons

Three types of statistical comparisons are possible at a site with more than one monitoring well for background and detection monitoring:

1) the current data for a well may be compared to the historical data for that same well (intrawell comparison);

2) one downgradient well may be compared to one or a group of upgradient wells (interwell comparison); and

3) a variation of the second type, a group of downgradient wells may be compared to a group of upgradient wells.

In the event that a SSI is detected and assessment monitoring is conducted, a fourth type of statistical comparison may be employed involving the comparison of well data to a constant limit such as a maximum concentration limit (MCL).

A serious difficulty associated with the comparison of downgradient water quality with upgradient water quality is the underlying assumption that the two sets of data are from water that has everywhere had an identical history. This assumption would imply that the upgradient and downgradient water would have the same infiltration time, period of contact with water-bearing sediments, chemical reactions with passing constituents, and no other significant differences from one part of the water-bearing zone to another. Although such assumptions are often necessary to make comparisons, they are generally not realistic with regard to natural ground water systems.

Intrawell comparisons are generally preferable to their interwell counterparts because they completely eliminate the spatial component of variability in samples. Due to the absence of spatial variability, the uncertainty associated with measured concentrations is decreased, making intrawell comparisons more sensitive to real releases (that is, false statistical negatives), and false positives. For sites where the hydraulic gradient is indefinite, the intrawell comparison is probably the most useful treatment of ground water sampling data. As per the above discussion, it is anticipated that intrawell comparisons will be applied to sampling data generated at the subject landfill following the completion of eight background monitoring events.

Flow charts can be valuable tools, aiding in the selection of appropriate statistical methods. A flow chart depicting methods likely to be used along with decision points of basis for making selections has been included in this GWSAP as ***Figure Att11-3***. It is anticipated that this format will allow for future flexibility contingent upon analytical data and minimize potential future changes to this plan. Information provided in the referenced figure was adapted from the example provided in ASTM publication *D 6312-98*.

Detailed descriptions of the selected statistical comparison method(s), decision points, and specific statistical treatments presented in the referenced flow chart will be provided to TCEQ in a statistical plan subsequent to the completion of background monitoring. Descriptions of

specific methods presented in the statistical plan will include appropriate information pertaining to normality of data, statistical intervals, and the handling on non-detects. A description of graphical methods to be applied to monitoring data will additionally be discussed in the statistical plan.

14.2 Independent Samples

Statistical methods generally used in ground water monitoring require that data be statistically independent for the results to be strictly valid. The sampling frequency must be established such that sufficient elapsed time occurs between monitoring events ensuring that consecutive samples are not taken from the "same" water. In general, the more permeable the water-bearing zone and the steeper the hydraulic gradient, the less time is necessary between monitoring events to facilitate the collection of statistically independent samples.

As discussed briefly in ***Section 10.0: Background Samples*** of this GWSAP, background monitoring events will be conducted quarterly for a duration of two years in order to construct a background database consisting of eight statistically independent samples per well. In order to confirm the adequacy of a quarterly monitoring program, site-specific lithologic and depth-to-water information including measurements/estimations of effective porosity, ground water gradient, and hydraulic conductivity will be used to calculate the horizontal ground water flow velocity. Given the diameter of site monitoring wells, it will be possible to determine whether flow velocities are such that water within the well casing will completely change within the three-month duration between monitoring events.

In the event that the site-specific determination of ground water flow velocity indicates that an alternate monitoring frequency is warranted (i.e., semi-annual as opposed to quarterly), a revised frequency will be proposed to TCEQ for remaining background and detection monitoring events as a permit modification request.

14.3 Seasonal Variation

Seasonal variation of ground water chemistry is well known in the state of Texas. Determination of seasonal influences requires adequate data, i.e., data collected over a full range of seasons, in order to make proper adjustments. Therefore, as described in ***Section 10.0: Background Sample*** of this GWSAP, a total of eight background sampling events will be conducted quarterly over a duration of two years in order to obtain data that reflects seasonal variations in ground water chemistry. By incorporating such data into the background monitoring database, it is anticipated that seasonal influences on the statistical treatment of data collected during detection monitoring events can be minimized.

15 REPORTING AND SUBMITTALS

Statistical analysis will be performed no later than 60 days after each semi-annual sampling event. In the event that statistical analysis of the groundwater analytical results indicates an initial SSI from background of any tested constituent at any downgradient monitor well, a notice in writing to the executive director and any local pollution agency with jurisdiction that has requested to be notified will be submitted within fourteen (14) days after the determination of the SSI (30 TAC §330.407 (b)). Three (3) copies (triplicate) of an annual detection monitoring report describing groundwater sampling and analyses results will be completed on state reporting forms (e.g. TCEQ-0312 or subsequent versions) and will be submitted to the TCEQ no later than ninety (90) days after the facility's last groundwater sampling event in a calendar year and will include information determined since the previously submitted annual report (30 TAC §330.407 (c)). In accordance with 30 TAC §330.407 (c)(1) to (6), the following information will be included in the annual detection monitoring report:

- A statement regarding whether a statistically significant increase has occurred over background values in any well during the previous calendar year period and the status of any statistically significant increase events;
- The results of all groundwater monitoring, testing, and analytical work obtained or prepared under the requirements of 30 TAC §330, including a summary of background groundwater quality values, groundwater monitoring analyses, statistical calculations, graphs, and drawings;
- The groundwater flow rate and direction in the uppermost aquifer. The groundwater flow rate and direction of groundwater flow shall be established using the data collected during the preceding calendar year's sampling events from the monitoring wells of the Detection Monitoring Program. All documentation used to determine the groundwater flow rate and direction of groundwater flow shall also be included in the annual report;
- A contour map of piezometric water levels in the uppermost aquifer based, at a minimum, upon concurrent measurement in all monitoring wells. All data or documentation used to establish the contour map will be included in the annual report;
- Recommendations for any changes; and
- Any other items requested by the executive director.

If an SSI occurs, assessment monitoring will be initiated according to the specified timelines presented in ***Section 12.0: Assessment Monitoring*** of this GWSAP unless it is demonstrated within the allotted time that the SSI is due to an error, natural variation, or another source. If initiated, assessment monitoring will be performed on a site-specific basis in accordance with *30 TAC §330.409*. Although the initiation of assessment monitoring does not require TCEQ

concurrence, these activities will be coordinated with TCEQ to confirm adequate characterization of potential ground water contamination.

In the event that statistical analysis of the groundwater analytical results indicates an initial SSI from background of any tested constituent at any downgradient monitor well, a notice in writing to the executive director and any local pollution agency with jurisdiction that has requested to be notified will be submitted within fourteen (14) days after the determination of the SSI (30 TAC §330.407 (b)). In the event the facility is in assessment monitoring, three (3) copies (triplicate) of an annual assessment monitoring report describing groundwater sampling and analyses results will be completed on state reporting forms (e.g. TCEQ-0312 or subsequent versions) and will be submitted to the TCEQ no later than sixty (60) days after the facility's last groundwater sampling event in a calendar year and will include information determined since the previously submitted annual report (30 TAC §330.409 (k)). Data may also be required to be submitted to the TCEQ on diskette or another format as specified by the TCEQ. In accordance with 30 TAC §330.409 (k)(1) to (6), the following information will be included in the annual assessment monitoring report:

- A statement whether a statistically significant level above a groundwater protection standard (GWPS) established in 30 TAC §330.407 (h) or (i) has occurred in any well during the previous calendar year period and the status of any statistically significant level events;
- The results of all groundwater monitoring, testing, and analytical work obtained or prepared under the requirements of 30 TAC §330, including a summary of background groundwater quality values, groundwater monitoring analyses, statistical calculations, graphs, and drawings;
- The groundwater flow rate and direction in the uppermost aquifer. The groundwater flow rate and direction of groundwater flow shall be established using the data collected during the preceding calendar year's sampling events from the monitoring wells of the Assessment Monitoring Program. All documentation used to determine the groundwater flow rate and direction of groundwater flow shall also be included in the annual report;
- A contour map of piezometric water levels in the uppermost aquifer based, at a minimum, upon concurrent measurement in all monitoring wells. All data or documentation used to establish the contour map will be included in the annual report;
- Recommendations for any changes; and
- Any other items requested by the executive director.

16 HEALTH AND SAFETY

A site-specific health and safety plan will be maintained independent of GWSAP due to the potential changes and updates of information such as emergency contacts and telephone numbers. This plan will include a summary of work tasks, site conditions, parties involved, and assigned responsibilities. The plan will describe emergency communications and response procedures with emphasis on the types of potential and existing hazards, exposure routes, Material Safety Data Sheets information, escape routes, personal protective equipment, first aid, and routes to the nearest hospital. A general site location map and detailed facility map will be included as part of the health and safety plan.

In summary, the permittee and/or subcontractors performing functions specific to activities associated with, and identified in the GWSAP, will establish and implement, and maintain appropriate health and safety plans.

LABORATORY CHECKLIST

Laboratory Data Package Cover Page

This data package consists of:

- ☐ This signature page, the laboratory review checklist, and the following reportable data:
- ☐ R1 Field chain-of-custody documentation;
- ☐ R2 Sample identification cross-reference;
- ☐ R3 Test reports (analytical data sheets) for each environmental sample that includes:
  - a) Items consistent with NELAC 5.13 or ISO/IEC 17025 Section 5.10
  - b) dilution factors,
  - c) preparation methods,
  - d) cleanup methods, and
  - e) if required for the project, tentatively identified compounds (TICs).
- ☐ R4 Surrogate recovery data including:
  - a) Calculated recovery (%R), and
  - b) The laboratory's surrogate QC limits.
- ☐ R5 Test reports/summary forms for blank samples;
- ☐ R6 Test reports/summary forms for laboratory control samples (LCSs) including:
  - a) LCS spiking amounts,
  - b) Calculated %R for each analyte, and
  - c) The laboratory's LCS QC limits.
- ☐ R7 Test reports for project matrix spike/matrix spike duplicates (MS/MSDs) including:
  - a) Samples associated with the MS/MSD clearly identified,
  - b) MS/MSD spiking amounts,
  - c) Concentration of each MS/MSD analyte measured in the parent and spiked samples,
  - d) Calculated %Rs and relative percent differences (RPDs), and
  - e) The laboratory's MS/MSD QC limits
- ☐ R8 Laboratory analytical duplicate (if applicable) recovery and precision:
  - a) the amount of analyte measured in the duplicate,
  - b) the calculated RPD, and
  - c) the laboratory's QC limits for analytical duplicates.
- ☐ R9 List of practical quantitation limits (PQLs) for each analyte for each method and matrix;
- ☐ R10 Other problems or anomalies.
- ☐ The Exception Report for every "No" or "Not Reviewed (NR)" item in laboratory review checklist.

Release Statement: I am responsible for the release of this laboratory data package. This data package has been reviewed by the laboratory and is complete and technically compliant with the requirements of the methods used, except where noted by the laboratory in the attached exception reports. By my signature below, I affirm to the best of my knowledge, all problems/anomalies, observed by the laboratory as having the potential to affect the quality of the data, have been identified by the laboratory in the Laboratory Review Checklist, and no information or data have been knowingly withheld that would affect the quality of the data.

Check, if applicable: ☐☐ This laboratory is an in-house laboratory controlled by the person responding to rule. The official signing the cover page of the rule-required report (for example, the APAR) in which these data are used is responsible for releasing this data package and is by signature affirming the above release statement is true.

Name (Printed)	Signature	Official Title (printed)	Date

Laboratory Review Checklist: Reportable Data

Laboratory Name:	LRC Date:
Project Name:	Laboratory Job Number:
Reviewer Name:	Prep Batch Number(s):

#[1]	A[2]	Description	Yes	No	NA[3]	NR[3]	ER#[4]
		Chain-of-custody (C-O-C)					
R1	OI	Did samples meet the laboratory's standard conditions of sample acceptability upon receipt?					
		Were all departures from standard conditions described in an exception report?					
R2	OI	**Sample and quality control (QC) identification**					
		Are all field sample ID numbers cross-referenced to the laboratory ID numbers?					
		Are all laboratory ID numbers cross-referenced to the corresponding QC data?					
R3	OI	**Test reports**					
		Were all samples prepared and analyzed within holding times?					
		Other than those results < PQL, were all other raw values bracketed by calibration standards?					
		Were calculations checked by a peer or supervisor?					
		Were all analyte identifications checked by a peer or supervisor?					
		Were sample quantitation limits reported for all analytes not detected?					
		Were all results for soil and sediment samples reported on a dry weight basis?					
		Were % moisture (or solids) reported for all soil and sediment samples?					
		If required for the project, TICs reported?					
R4	O	**Surrogate recovery data**					
		Were surrogates added prior to extraction?					
		Were surrogate percent recoveries in all samples within the laboratory QC limits?					
R5	OI	**Test reports/summary forms for blank samples**					
		Were appropriate type(s) of blanks analyzed?					
		Were blanks analyzed at the appropriate frequency?					
		Were method blanks taken through the entire analytical process, including preparation and, if applicable, cleanup procedures?					
		Were blank concentrations < PQL?					
R6	OI	**Laboratory control samples (LCS):**					
		Were all COCs included in the LCS?					
		Was each LCS taken through the entire analytical procedure, including prep and cleanup steps?					
		Were LCSs analyzed at the required frequency?					
		Were LCS (and LCSD, if applicable) %Rs within the laboratory QC limits?					
		Does the detectability data document the laboratory's capability to detect the COCs at the MDL used to calculate the SQLs?					
		Was the LCSD RPD within QC limits?					
R7	OI	**Matrix spike (MS) and matrix spike duplicate (MSD) data**					
		Were the project/method specified analytes included in the MS and MSD?					
		Were MS/MSD analyzed at the appropriate frequency?					
		Were MS (and MSD, if applicable) %Rs within the laboratory QC limits?					
		Were MS/MSD RPDs within laboratory QC limits?					
R8	OI	**Analytical duplicate data**					
		Were appropriate analytical duplicates analyzed for each matrix?					
		Were analytical duplicates analyzed at the appropriate frequency?					
		Were RPDs or relative standard deviations within the laboratory QC limits?					
R9	OI	**Practical quantitation limits (PQLs):**					
		Are the PQLs for each method analyte included in the laboratory data package?					
		Do the PQLs correspond to the concentration of the lowest non-zero calibration standard?					
		Are unadjusted PQLs included in the laboratory data package?					
R10	OI	**Other problems/anomalies**					
		Are all known problems/anomalies/special conditions noted in this LRC and ER?					
		Were all necessary corrective actions performed for the reported data?					
		Was applicable and available technology used to lower the SQL minimize the matrix interference affects on the sample results?					

1. Items identified by the letter "R" must be included in the laboratory data package submitted in required report(s). Items identified by the letter "S" should be retained and made available upon request for the appropriate retention period.
2. O = organic analyses; I = inorganic analyses (and general chemistry, when applicable);
3. NA = Not applicable; and NR = Not reviewed;
4. ER# = Exception Report identification number (an Exception Report should be completed for an item if "NR" or "No" is checked on the LRC)

Laboratory Review Checklist: Reportable Data	
Laboratory Name:	LRC Date:
Project Name:	Laboratory Job Number:

Reviewer Name:			Prep Batch Number(s):					
#[1]	A[2]	Description	Yes	No	NA[3]	NR[4]	ER#[5]
S1	OI	**Initial calibration (ICAL)**					
		Were response factors and/or relative response factors for each analyte within QC limits?					
		Were percent RSDs or correlation coefficient criteria met?					
		Was the number of standards recommended in the method used for all analytes?					
		Were all points generated between the lowest and highest standard used to calculate the curve?					
		Are ICAL data available for all instruments used?					
		Has the initial calibration curve been verified using an appropriate second source standard?					
	OI	**Initial and continuing calibration verification (ICCV and CCV) and continuing calibration**					
		Was the CCV analyzed at the method-required frequency?					
		Were percent differences for each analyte within the method-required QC limits?					
		Was the ICAL curve verified for each analyte?					
		Was the absolute value of the analyte concentration in the inorganic CCB < MDL?					
	O	**Mass spectral tuning:**					
		Was the appropriate compound for the method used for tuning?					
		Were ion abundance data within the method-required QC limits?					
	O	**Internal standards (IS):**					
		Were IS area counts and retention times within the method-required QC limits?					
S5	OI	**Raw data (NELAC section 1 appendix A glossary, and section 5.12 or ISO/IEC 17025 section 4.12.2)** ***(ONLY USE DATA FOR EPA LEVEL 3 QA/QC REVIEW, IF RAW DATA NOT APPLICATBLE, THEN CHANGE APPROPRIATELY).***					
		Were the raw data (for example, chromatograms, spectral data) reviewed by an analyst?					
		Were data associated with manual integrations flagged on the raw data?					
	O	**Dual column confirmation**					
		Did dual column confirmation results meet the method-required QC?					
	O	**Tentatively identified compounds (TICs):**					
		If TICs were requested, were the mass spectra and TIC data subject to appropriate checks?					
	I	**Interference Check Sample (ICS) results:**					
		Were percent recoveries within method QC limits?					
	I	**Serial dilutions, post digestion spikes, and method of standard additions**					
		Were percent differences, recoveries, and the linearity within the QC limits specified in the method?					
	OI	**Method detection limit (MDL) studies**					
		Was a MDL study performed for each reported analyte?					
		Is the MDL either adjusted or supported by the analysis of DCSs?					
	OI	**Proficiency test reports:**					
		Was the laboratory's performance acceptable on the applicable proficiency tests or evaluation studies?					
	OI	**Standards documentation**					
		Are all standards used in the analyses NIST-traceable or obtained from other appropriate sources?					
	OI	**Compound/analyte identification procedures**					
		Are the procedures for compound/analyte identification documented?					
	OI	**Demonstration of analyst competency (DOC)**					
		Was DOC conducted consistent with NELAC Chapter 5C or ISO/IEC 4?					
		Is documentation of the analyst's competency up-to-date and on file?					
	OI	**Verification/validation documentation for methods** (NELAC Chap 5 or ISO/IEC 17025 Section 5)					
		Are all the methods used to generate the data documented, verified, and validated, where applicable?					
	OI	**Laboratory standard operating procedures (SOPs):**					
		Are laboratory SOPs current and on file for each method performed?					

1 Items identified by the letter "R" should be included in the laboratory data package submitted to the TCEQ in the required report(s). Items identified by the letter "S" should be retained and made available upon request for the appropriate retention period.
2 O = organic analyses; I = inorganic analyses (and general chemistry, when applicable).
3 NA = Not applicable.
4 NR = Not Reviewed.
5 ER# = Exception Report identification number (an Exception Report should be completed for an item if "NR" or "No" is checked).

Memorandum

SAIC

To: TCEQ

From: Fred J. Doran, SAIC

Subject: Appendix 3M, Attachment 2

Date: November 2, 2012

The attached NMOC Monitoring Results were completed in 2007 and reference MSW Permit No. 729A throughout. It should be noted that the attached results are applicable to MSW Permit No. 729B and should be referenced within the document as part of MSW Permit No. 729B.

Municipal Solid Waste Landfill
40 CFR Part 60, Subpart WWW Reporting Submittal Forms

Revised NMOC Emission Rate Report (Tier 2) Submittal Form

Landfills that have 50 Mg/year or greater of NMOC emission rate as determined by using the Tier 1 formulas and defaults must submit this report if they choose not to submit a Collection and Control System Design Plan, but choose instead to use the Tier 2 procedures to recalculate the NMOC emission rate. ***Submit this form to the Report Submittal Address Number 1.***

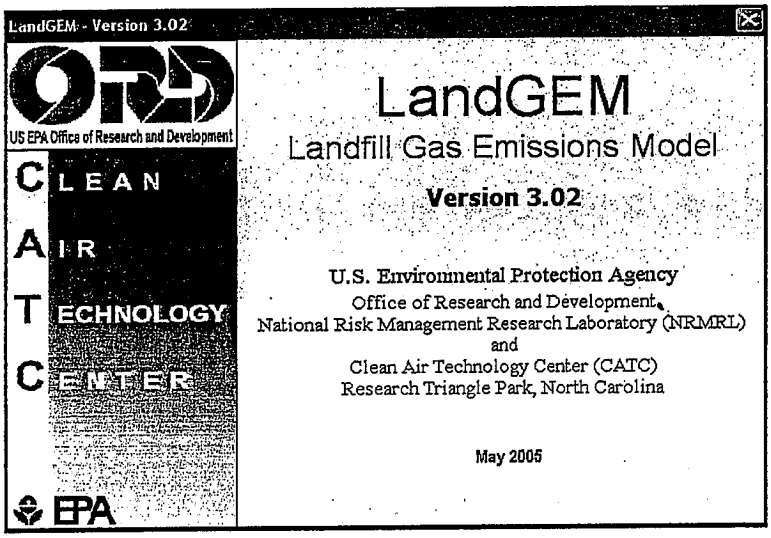
Title: Director of Environmental Services			
Check each line in the appropriate boxes, as applicable			
Was the report submitted within 180 days of the first calculated exceedance of 50 Mg/yr?			☒ YES ☐ NO
If the recalculated NMOC emission was less than 50 Mg/yr, then was annual period reporting resumed?			☐ YES ☐ NO
If the recalculated NMOC emission rate is greater than 50 Mg/yr, did the owner/operator submit a Collection and Control System Design Plan, or recalculated the NMOC emission rate according to Tier 3 procedures?			☐ YES ☐ NO



Summary Report

Landfill Name or Identifier: McCombs #729A, Inventory, waste report data

Date: Wednesday, April 11, 2007

Description/Comments:

About LandGEM:

First-Order Decomposition Rate Equation: $$Q_{CH_4} = \sum_{i=1}^{n} \sum_{j=0.1}^{1} kL_o \left(\frac{M_i}{10} \right) e^{-kt_{ij}}$$

Where,

Q_{CH4} = annual methane generation in the year of the calculation ($m^3/year$)
i = 1-year time increment
n = (year of the calculation) - (initial year of waste acceptance)
j = 0.1-year time increment
k = methane generation rate ($year^{-1}$)
L_o = potential methane generation capacity (m^3/Mg)
M_i = mass of waste accepted in the ith year (Mg)
t_{ij} = age of the jth section of waste mass M_i accepted in the ith year (*decimal years*, e.g., 3.2 years)

LandGEM is based on a first-order decomposition rate equation for quantifying emissions from the decomposition of landfilled waste in municipal solid waste (MSW) landfills. The software provides a relatively simple approach to estimating landfill gas emissions. Model defaults are based on empirical data from U.S. landfills. Field test data can also be used in place of model defaults when available. Further guidance on EPA test methods, Clean Air Act (CAA) regulations, and other guidance regarding landfill gas emissions and control technology requirements can be found at http://www.epa.gov/ttnatw01/landfill/landflpg.html.

LandGEM is considered a screening tool — the better the input data, the better the estimates. Often, there are limitations with the available data regarding waste quantity and composition, variation in design and operating practices over time, and changes occurring over time that impact the emissions potential. Changes to landfill operation, such as operating under wet conditions through leachate recirculation or other liquid additions, will result in generating more gas at a faster rate. Defaults for estimating emissions for this type of operation are being developed to include in LandGEM along with defaults for convential landfills (no leachate or liquid additions) for developing emission inventories and determining CAA applicability. Refer to the Web site identified above for future updates.

Input Review

LANDFILL CHARACTERISTICS

Landfill Open Year	1977	
Landfill Closure Year (with 80-year limit)	2046	
Actual Closure Year (without limit)	*2046*	
Have Model Calculate Closure Year?	No	
Waste Design Capacity		*megagrams*

MODEL PARAMETERS

Methane Generation Rate, k	0.020	$year^{-1}$
Potential Methane Generation Capacity, L_o	100	m^3/Mg
NMOC Concentration	270	*ppmv as hexane*
Methane Content	50	*% by volume*

GASES / POLLUTANTS SELECTED

Gas / Pollutant #1:	Total landfill gas
Gas / Pollutant #2:	Methane
Gas / Pollutant #3:	Carbon dioxide
Gas / Pollutant #4:	NMOC

	1,2-Dichloroethane (ethylene dichloride) - HAP/VOC	0.41	98.96		
	1,2-Dichloropropane (propylene dichloride) - HAP/VOC	0.18	112.99		
	2-Propanol (isopropyl alcohol) - VOC	50	60.11		
	Acetone	7.0	58.08		
	Acrylonitrile - HAP/VOC	6.3	53.06		
	Benzene - No or Unknown Co-disposal - HAP/VOC	1.9	78.11		
	Benzene - Co-disposal - HAP/VOC	11	78.11		
	Bromodichloromethane - VOC	3.1	163.83		
	Butane - VOC	5.0	58.12		
	Carbon disulfide - HAP/VOC	0.58	76.13		
	Carbon monoxide	140	28.01		
	Carbon tetrachloride - HAP/VOC	4.0E-03	153.84		
	Carbonyl sulfide - HAP/VOC	0.49	60.07		
	Chlorobenzene - HAP/VOC	0.25	112.56		
	Chlorodifluoromethane	1.3	86.47		
	Chloroethane (ethyl chloride) - HAP/VOC	1.3	64.52		
	Chloroform - HAP/VOC	0.03	119.39		
	Chloromethane - VOC	1.2	50.49		
	Dichlorobenzene - (HAP for para isomer/VOC)	0.21	147		
	Dichlorodifluoromethane	16	120.91		
	Dichlorofluoromethane - VOC	2.6	102.92		
	Dichloromethane (methylene chloride) - HAP	14	84.94		
	Dimethyl sulfide (methyl sulfide) - VOC	7.8	62.13		
	Ethane	890	30.07		
	Ethanol - VOC	27	46.08		

Pollutant Parameters (Continued)

		Gas / Pollutant Default Parameters:		*User-specified Pollutant Parameters:*	
	Compound	Concentration (*ppmv*)	Molecular Weight	Concentration (*ppmv*)	Molecular Weight
Pollutants	Ethyl mercaptan (ethanethiol) - VOC	2.3	62.13		
	Ethylbenzene - HAP/VOC	4.6	106.16		
	Ethylene dibromide - HAP/VOC	1.0E-03	187.88		
	Fluorotrichloromethane - VOC	0.76	137.38		
	Hexane - HAP/VOC	6.6	86.18		
	Hydrogen sulfide	36	34.08		
	Mercury (total) - HAP	2.9E-04	200.61		
	Methyl ethyl ketone - HAP/VOC	7.1	72.11		
	Methyl isobutyl ketone - HAP/VOC	1.9	100.16		
	Methyl mercaptan - VOC	2.5	48.11		
	Pentane - VOC	3.3	72.15		
	Perchloroethylene (tetrachloroethylene) - HAP	3.7	165.83		
	Propane - VOC	11	44.09		
	t-1,2-Dichloroethene - VOC	2.8	96.94		
	Toluene - No or Unknown Co-disposal - HAP/VOC	39	92.13		
	Toluene - Co-disposal - HAP/VOC	170	92.13		
	Trichloroethylene (trichloroethene) - HAP/VOC	2.8	131.40		
	Vinyl chloride - HAP/VOC	7.3	62.50		
	Xylenes - HAP/VOC	12	106.16

RE: Tier 2 NMOC McCombs Landfill

Dear Mr. Garza,

Archana Inc. submits this report, which presents the results for the Tier II analysis of the McCombs Landfill. These results of the Tier II testing were used to calculate the potential Non-methane Organic Carbon (NMOC) emissions at the landfill. Tier II sampling and analysis were performed in general accordance with 40 CFR 60.754(a) (3) using Method 25-C and Method 3-C to evaluate NMOC concentrations. Included in this letter, you will find field sampling techniques, results of laboratory testing.

Field Sampling

Environmental Services Network South completed sampling of landfill gas at the following sites shown in Figure 1 attached in this letter. Sampling depth is 6' (3' of screen), the installation of inline water trap at top of probe rod, which connects the summa canister assembly (vacuum gauge, cross flow valve to Landtech, and flow limiter) to the summa canister. Test the gases with the Landtech unit to determine that ambient air has not been drawn into the system. Log the O_2, CO_2, and CH_4 readings. The combined CO_2 and CH_4 should be greater than 90%, and the O_2 reading should be in the 1% range. Once methane and carbon dioxide levels have become constant, the summa valve and the 2-way valve are opened sampling of the landfill gas at a rate of approximately 250ml/min. A 1-liter sample will be taken in 4 minutes. The flow limiter may need to be adjusted due to changes in vacuum. At 250ml/min the vacuum will drop .1"hg every 5-6 seconds. The samples were composite three points per canister and were shipped to Air Technologies for analysis.

Laboratory Analysis

Landfill gas was submitted to Air Technologies for testing. As required by Method 25-C, NMOC concentrations were corrected for nitrogen and moisture content. Using the corrected results, a NMOC concentration of hexane was measured. Results of analytical testing are attached to this report.
